of α -nitroso- β -naphthol and cupferron (nitroso-phenylhydroxylamine-ammonium) is summarised and criticised, and the cases indicated in which these reagents may be used for the separation and estimation of metals. For the separation of copper neither of the reagents offers any real advantages over known methods, except in the case of the separation of copper from arsenic, and especially from antimony, by means of nitroso- β -naphthol. Cupferron is preferable to nitrosonaphthol for the separation of iron, the permissible limit of free mineral acid in the solution being higher and the precipitate less voluminous. Nitrosonaphthol is of value chiefly as a precipitant for cobalt, and in lesser degree for palladium. Cupferron is a valuable precipitant for iron and also for titanium, zirconium, and vanadium. (See J. Chem. Soc., Jan., 1920.)—T. H. P.

Molybdenum and tungsten; Colour reactions of — II. G. A. Barbjeri. Atti R. Accad. Lincei, 1919, 28, i., 390—392. (See this J., 1919, 881 A.)

IF the acetic acid of Braun's reagent is replaced by hydrochloric or sulphuric acid (see Péchard, Comptes rendus, 1894, 118, 804), the compound $NH_4SCN.(NH_4)_2O.4MoO_3.5H_2O$, is always formed, no matter whether ammonium permolybdate or the tri- or tetra- or normal molybdate is used with the ammonium thiocyanate. From potassium trimolybdate and thiocyanate in presence of acetic acid, the corresponding potassium compound, $KSCN.K_2O.4MoO_3.5H_2O$ is formed. (See also J. Chem. Soc., Jan., 1920.)—T. H. P.

Sodium thiosulphate; Titration of solutions of — I. M. Kolthoff. Pharm. Weekblad, 1919, 56, 644—657.

THE purification and application of various substances for the titration of thiosulphate solutions are described, and their relative merits discussed. A method for the detection and estimation of small quantities of free chromic acid or potassium chromate in potassium bichromate is based on the fact that the conductivity of a bichromate solution containing chromic acid decreases slightly on the addition of standard alkali until the free acid has been neutralised. After this point the conductivity increases rapidly on the further addition of alkali. A similar discontinuity in the curve is obtained when acid is added to a bichromate solution containing chromate. Pure bichromate for analytical purposes should be fused in an electric furnace before use. All the other substances examined—iodine, crystallised oxalic acid, cyanogen iodide, potassium iodate and bromate are easily purified and are equally suitable for the estimation of thiosulphate, the error in the titration being in each case less than 0.1%. The greatest error, 0.07%, was observed in titrating with bichromate.

—W. S. M.

Cerium; Detection of — F. Feigl. Oesterr. Chem.-Zeit., 1919, 22, 124—126. Chem. Zentr., 1919, 90, IV, 592.

CERIUM oxide, moistened with an acetic acid solution of benzidine gives a bright blue coloration. Other cerous and ceric compounds give the reaction, with the exception of cerous fluoride, cerous carbonate, and cerium bisulphate. The most sensitive reaction is obtained by rendering the solution alkaline, boiling, filtering a portion, and sprinkling the filter with the benzidine solution; 0.02 mgrm. of cerium in a litre can be recognised in this manner. The other metals of the ammonium sulphide group of the rare earths, except thallium, do not give the reaction, which depends upon oxidation by means of an oxygen-carrier, and all other oxidising agents, especially manganese, cobalt, thallium, and chromium must be absent. Feebly acid iron solu-

tions also give the reaction; alkaline solutions do not. Since ferric hydroxide carries down considerable amounts of cerium, the latter is best precipitated as fluoride in the presence of iron and converted into hydroxide.—J. H. J.

Uranium; Colorimetric determination of small quantities of —. Müller. Chem.-Zeit., 1919, 43, 739—740.

The red coloration obtained when a dilute (e.g., 0.02%) uranium salt solution is treated with sodium salicylate solution may be utilised for the colorimetric determination of the metal, the coloration being compared with that given by a known amount of uranium under similar conditions. Free mineral acids and acetic acid must not be present; if the solution contains free mineral acid, sodium acetate should be added and the acetic acid then expelled by evaporation. Further, iron salts, alcohol, and acetone interfere with the reaction, but neutral alkali salts appear to be without effect.—W. P. S.

Hydrocyanic acid; Detection of — in a case of poisoning. Its post-mortem transformation into thiocyanic acid. L. Chelle. Comptes rend., 1919, 169, 852—854. (See also this J., 1919, 899 A, 900 A.)

In the case of a dog poisoned by potassium cyanide, hydrocyanic acid as such but no thiocyanic acid was found in the brain, lungs, and blood two hours after death. Eight days after death thiocyanic acid but no hydrocyanic acid was found. Further, in the case of the brains and lungs the amount of thiocyanic acid found was far more than equivalent to the amount of hydrocyanic acid found in these organs two hours after death. To ensure estimation of all the toxic principle it is desirable to wait for a few days after death until putrefaction and consequent cytotoxicity has set in before performing the analysis.—W. G.

Acetylene, ethylene, and benzene. Treadwell and Tauber. See II A.

Wool and silk. Waentig. See V.

Mixed pulp in paper. See V.

Ferrocyanides. Kelley and Bohn. See VII.

Lead oxides. Andersen. See VII.

PATENTS.

Pyrometer or temperature alarm instrument. J. F. J. Malone, Newcastle-on-Tyne. Eng. Pat. 134,498, 27.5.19. (Appl. 13,357/19.)

The portion of the pyrometer to be immersed in the medium of which the temperature is required consists of members composed of two materials having different coefficients of linear expansion; and the relative changes in length of these members is transmitted to an indicating device by connecting and supporting rods made of the same materials

and having the same cross-sectional areas, so that the indications are not affected by thermal changes in the rods. In one form of the apparatus one of the working members is a tube (steel) surrounding the other member (invar), and the free end of the latter is secured to a sleeve adapted to slide within the tube. One end of the tube is attached to a fixed coupling, to which one set of transmitting rods is also secured, the other set of transmitting rods being secured to the sliding sleeve. The apparatus may be provided with an alarm device.

—W. E. F. P.

Still head. S. F. Dufton, Leeds. Eng. Pat. 134,629, 11.11.18. (Appl. 18,415/18.)

In a still head, a spiral passage is arranged within an annulus, the width of the latter being graduated from top to bottom so that the passage is only just large enough at any point to allow the vapour and condensed liquid to pass each other freely at the rate of distillation desired. The apparatus is constructed by winding a wire round a core, or by making a similar arrangement by casting or turning, and fitting the core inside a tube. A number of units may be combined to form a multiple still head; and the loss of heat from a single or multiple head may be regulated by surrounding the apparatus with a vacuum vessel. (See also this J., 1919, 45 T.)—W. E. F. P.

Urine; Medical analysis of — by the combined use of tungstic acid and other reagents. H. C. Ross, London. Eng. Pat. 134,710, 7.11.18. (Appl. 2267/19.)

When 0.2 c.c. of a reagent composed of an aqueous solution of colloidal tungstic acid 12%, acetic or tartaric acid 10%, and sodium potassium tartrate 2.5%, is added to 2 c.c. of urine, the presence of albumin will cause a precipitate. If the tungstic acid is impure, excess of urates also produces a precipitate, but this re-dissolves on boiling. In the latter case a diabetic condition is indicated, and the hot solution is further tested for reducing sugars by adding a tablet containing copper sulphate 0.02 gm., sodium carbonate 0.01 gm., and calcium oxide 0.01 gm. If desired both reagents may be prepared in tablet form.—G. F. M.

Gas-testing machine. L. A. Stenger, Denver, Colo. U.S. Pat. 1,320,584, 4.11.19. Appl., 14.10.18.

In a gas analyser, a gas chamber, which communicates with a solution tank and a pressure gauge, is charged with a predetermined volume of gas and closed to the atmosphere. The solution, in the form of spray, is then caused to pass through the gas chamber and back to the tank.—W. E. F. P.

[Combustible] gases; Method and apparatus for testing —. A. B. Lamb and A. T. Larson, U.S. Army. U.S. Pat. (A) 1,321,063 and (N) 1,321,064, 4.11.19. Appl., 17.2.19.

In apparatus for determining combustible gases at low concentrations, the gaseous mixture is caused to pass (A) over catalytic material in the vicinity of a thermo-junction, or (N) around one of a pair of electrically heated wires the change in resistance of which is measured.—W. E. F. P.

Inflammable gases in gas mixtures; Estimation of —. R. Naumann, Berlin-Schlachtensee. Ger. Pat. 313,858, 18.1.18.

The inflammable gas is estimated by burning at a catalytic surface, the rise in temperature of the latter being noted. The speed of flow of the gas mixture can be varied, and that speed is used which gives the greatest rise in temperature.—W. P.

Absorbent. A. B. Lamb, U.S. Army, and C. R. Hoover, Middletown, Conn. U.S. Pat. 1,321,061, 4.11.19. Appl., 28.12.18.

As oxidising, absorbent material is prepared by

treating iodic anhydride with sulphuric anhydride in the presence of a small amount of water.
—W. E. F. P.

Carbon monoxide in hydrogen. Eng. Pat. 134,243.
See VII.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Abogado. Process and apparatus for heating liquids. 30,834 and 30,835. Dec. 9.
Arraghi. Filters. 30,675. Dec. 8.
Beanes. Machines for drying and/or roasting granular substances. 31,945. Dec. 19.
Bourdet. Apparatus for treating pulverulent materials. 31,482. Dec. 16.
Bury, and Skinningrove Iron Co. 31,066. See XI.
Harris. Settling vats. 31,299. Dec. 13.
Hort. Method of evaporation. 30,821. Dec. 9.
Imbery. Furnaces. 31,324. Dec. 15.
Norske Aktieselskab for Elektrokemisk Industri. Manufacture of porous material. 31,371. Dec. 15. (Norway, 16.12.18.)
Rostados. Method of drying and dry storage of merchandise, foodstuffs, etc. 31,987. Dec. 20.
Soc. Anon. des Etabl. A. Olier. Filter presses. 31,298. Dec. 19. (Fr., 31.1.19.)
Soc. l'Air Liquide. Separation of constituents of gaseous mixtures liquefiable at very different temperatures. 31,696. Dec. 17. (Fr., 4.2.14.)

COMPLETE SPECIFICATIONS ACCEPTED.

10,453, 10,458, and 10,459 (1918). Elektro-Osmose A.-G. See XI.
20,253 (1918). Barron and Barron. Impact grinders. (135,955.) Dec. 17.
20,739 (1918). Fuller and Bedford. Furnaces. (136,270.) Dec. 24.
21,057 (1918). Webster. Filter presses. (135,976.) Dec. 17.
21,756 (1918). Acton. Apparatus for separating solid particles from liquids. (135,992.) Dec. 17.
21,759 (1918). Alexander (United Filters Corporation). Continuous vacuum filters. (136,309.) Dec. 24.
2097 (1919). South Metropolitan Gas Co., and Chandler. Gas furnaces. (136,356.) Dec. 24.
13,336 (1919). Mond (International Precipitation Co.). Separation of suspended material from gases. (136,464.) Dec. 24.
19,318 (1919). Chenard. Apparatus for fractional distillation. (130,992.) Dec. 17.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Brown and Hoover. Working oil shales. 30,930. Dec. 10.
Dale. Coal etc. briquettes, and manufacture thereof. 31,820. Dec. 18.
Davidson. Preparation of peat fuel for producer gas. 31,074. Dec. 11.
Davidson. Preparation of peat fuel for general purposes. 31,075. Dec. 11.
Duckham, and Woodall, Duckham, and Jones. Introduction of steam into vertical retorts or ovens. 31,799. Dec. 18.

France. 31,821. See X.
Goold (Universal Oil Products Co.). Process of converting hydrocarbons. 31,138. Dec. 12.
Knibbs. Treatment of hydrocarbon oil. 32,019. Dec. 20.

McEwen, and Underfeed Stoker Co. Carbonisation or destructive distillation. 31,073. Dec. 11.
Marshall. Manufacture of incandescent gas mantles. 31,853. Dec. 19.

Rushton. Composite fuel, and manufacture of same. 31,196. Dec. 12.
Soc. Indus. de Prod. Chimiques. Recovery of ammonia from coke-oven etc. gases. 31,688 and 31,689. Dec. 17. (Fr., 27.5.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

10,972 (1917). Wellington. Production of gas. (136,186.) Dec. 24.
3715 (1918). Lynn. Producer-gas plant. (136,189.) Dec. 24.
15,809 (1918). Rowntree and Co., and Fryer. See III.
18,392 (1918). Dellwik, and Techno-Chemical Laboratories, Ltd. Combustion of fuel. (136,212.) Dec. 24.
20,002 (1918). Umsted. Purifying gas and obtaining by-products. (135,931.) Dec. 17.
20,392 (1918). Climie and Lees. Gas-producing plant. (135,959.) Dec. 17.
901 (1919). Bamber and Abrahams. Gas-producers. (136,333.) Dec. 24.
2097 (1919). South Metropolitan Gas Co., and Chandler. See I.
5002 (1919). Cummins. Vertical gas retort settings. (136,398.) Dec. 24.
9903 (1919). Berglund. See X.
11,177 (1919). Marks (U.S. Industrial Alcohol Co.). Liquid fuel. (136,452.) Dec. 24.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Badier and others. 31,663 and 31,664. See XX.
Boot's Pure Drug Co., and Marshall. 31,660. See XX.
Green and others. 31,978. See XX.

COMPLETE SPECIFICATIONS ACCEPTED.

15,809 (1918). Rowntree and Co., and Fryer. Combustion of pitch. (135,886.) Dec. 17.
10,864 (1919). Marks (Soc. Franco-Belge de Fours à Coke). Continuous distillation and fractionation of crude benzols etc. (136,450.) Dec. 24.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Imray (Soc. Chem. Industry in Basle). Manufacture of monoazo dyestuffs. 30,839. Dec. 9.
Ward. Scarlet dye. 31,234. Dec. 13.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Fort, Lumsden, Mackenzie, and Robinson. Treatment and purification of yarns and fabrics composed of vegetable fibres. 31,292. Dec. 13.
Frood. Manufacture of fibrous fabrics or compositions for frictional and wearing purposes. 30,760. Dec. 9.
Great Northern Paper Co. Manufacture of paper. 31,790. Dec. 18. (U.S., 14.3.18.)
McCredie. Retting flax, hemp, ramie, etc. 31,289. Dec. 13.
Müller. Manufacture of cellulose compounds. 31,377. Dec. 15.
Soc. Gillet et Fils. Treatment of vegetable fibres. 31,188—31,192. Dec. 12. (Ger., 13.12.18, and 12.6.23.7, and 2.9.19.)

VI.—BLEACHING; DYEING; PRINTING; FINISHING.**APPLICATIONS.**

Chambers. Process of metallising lace etc. 31,039. Dec. 11.
McKittrick and Pethick. Printing or dyeing patterns or ornamenting fabrics. 31,052. Dec. 11.
Maupai. Process of dyeing raw silk. 30,951. Dec. 10.

COMPLETE SPECIFICATION ACCEPTED.

21,134 (1919). Calico Printers' Assoc., Turner, and Fournaux. Ageing-machines. (136,507.) Dec. 24.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.**APPLICATIONS.**

Douglas. Apparatus for manufacture of sulphate of ammonia. 31,970. Dec. 20.
Field, and Metals Extraction Corporation. Purification of zinc solutions. 31,936. Dec. 19.
Harger. Manufacture of hydrogen. 31,849. Dec. 19.
Marks (West Coast Kalsomine Co.). Manufacture of iron compounds. 30,832. Dec. 9.
Newall. Means for calcining magnesite etc. 30,816. Dec. 9.
Pedersen. Extraction of sulphur from sulphide ores. 30,977. Dec. 10.
Pestalozza. Apparatus for direct production of hypochlorites. 31,908 and 31,909. Dec. 19.
Soc. Indus. de Produits Chimiques. 31,688 and 31,689. *See II.*
Welter. Production of soda or mixtures thereof with other substances. 31,816. Dec. 18. (Ger., 23,318.)

COMPLETE SPECIFICATIONS ACCEPTED.

3792 (1918). Partington, Jones, and Brownson. Production of ammonium nitrate. (136,190.) Dec. 24.
17,364 (1918). Haslup. Fixation of atmospheric nitrogen and production of ammonia. (135,889.) Dec. 17.
21,659 (1918). Norske Aktieselskab for Elektrokemisk Industri. Production of alumina poor in iron. (125,578.) Dec. 24.
1442 (1919). Parsons and Jones. Purification of ammonia. (136,342.) Dec. 24.
7872 (1919). General Chemical Co. Apparatus for the synthetic production of ammonia. (124,762.) Dec. 17.
14,950 (1919). Bergve. Production of alkali sulphides. (129,629.) Dec. 24.

VIII.—GLASS; CERAMICS.**APPLICATION.**

Laycock and Laycock. Annealing lehrs or kilns for glass etc. 31,877. Dec. 19.

COMPLETE SPECIFICATION ACCEPTED.

19,688 (1919). Marlow. Ovens or kilns for the manufacture of tiles, pottery, or other ware. (136,127.) Dec. 17.

IX.—BUILDING MATERIALS.**APPLICATIONS.**

Armstrong, Lee, and Pearson. Production of bricks, tiles, etc. 30,758. Dec. 9.
Bagguley. Manufacture of bricks etc. 30,894. Dec. 10.
Laurie, Sutcliffe, and Sutcliffe, Speakman and Co. Mixtures for blocks or slabs for building etc. 30,805. Dec. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

2035 (1919). Scarlett. Cement. (136,355.) Dec. 24.

9678 (1919). Dale. Manufacture of concrete. (136,075.) Dec. 17.
15,154 (1919). Scott, Scott, and Scott. Cement. (136,478.) Dec. 21.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.**APPLICATIONS.**

Adams and Melrose. Solder for aluminium and its alloys. 30,788. Dec. 9.
Annable, and Nickel Concentration, Ltd. Extraction of nickel from its ores. 31,699. Dec. 17.
Ballantine. Production of alloys. 31,761. Dec. 18.
British and Foreign Chemical Producers (Rheinische Kampferfabrik). Pickling iron or steel. 30,960. Dec. 10.
Bury, and Skinningrove Iron Co. 31,066. *See XI.*
Collins. Purification of tin. 30,950. Dec. 10.
Collins. Winning tin. 30,951. Dec. 10.
Elmore. Treatment of argentiferous lead-zinc ores. 31,791. Dec. 18.
Elmore. Treatment of argentiferous sulphide ores. 31,797. Dec. 18.
France. Mineral washing processes. 31,821. Dec. 18.
Hadfield. Manufacture of alloy steel. 30,724. Dec. 8.
Hadfield. Manufacture of steel. 30,725. Dec. 8.
Johanson. Treating weakly magnetic iron ore containing sulphides. 31,814. Dec. 18.
Pedersen. 30,977. *See VII.*

COMPLETE SPECIFICATIONS ACCEPTED.

18,529 (1918). Harvey. Metal-melting furnace. (136,213.) Dec. 24.
20,541 (1918). Tucker, Edser, and Minerals Separation, Ltd. Concentration of ores. (136,255.) Dec. 24.
20,550 (1918). Haywood. Copper-aluminium alloy. (135,963.) Dec. 17.
20,761 (1918). Amalgamated Zinc Co., and Ganelin. Recovery of lead and silver from sulphide ores etc. (135,968.) Dec. 17.
9903 (1919). Berglund. Apparatus for sintering concentrates, distilling shale, etc. (136,076.) Dec. 17.
10,755 (1919). Lenoir. Manufacture of manganese and its alloys in the electric furnace. (126,303.) Dec. 17.

XI.—ELECTRO-CHEMISTRY.**APPLICATIONS.**

British Thomson-Houston Co., Hastings, and Laycock. Electric furnaces. 31,899. Dec. 19.
Bury, and Skinningrove Iron Co. Apparatus for electrostatic deposition of particles from gases. 31,066. Dec. 11.
Gush. Apparatus for purifying liquids by electrolytic treatment. 31,642. Dec. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

10,453, 10,458, 10,459 (1918). Elektro-Osmose A.-G. Apparatus for electro-osmotically removing water etc. from materials. (135,815, 135,819, 135,820.) Dec. 24.
19,671 (1918). Bibby. Electric arc shaft furnaces. (135,905.) Dec. 17.
20,988 (1918). Joel. Electric accumulators. (136,282.) Dec. 21.
3024 (1919). Cooke. Storage batteries. (136,026.) Dec. 17.
3555 (1919). Moore. Electric arc furnaces. (136,034.) Dec. 17.
10,755 (1919). Lenoir. *See X.*
17,988 (1919). Winne. Electric furnace control apparatus. (136,500.) Dec. 21.

XII.—FATS; OILS; WAXES.

APPLICATION.

Marlborough. Liquid detergents etc. 30,653. Dec. 8.

COMPLETE SPECIFICATION ACCEPTED.

20,079 (1918). Blichfeldt. Apparatus for use in the manufacture of margarine or the like. (135,939.) Dec. 17.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Ioco Proofing Co., Vickers, Ltd., and Nuttall. Condensation of phenolic bodies with aldehyde compounds. 31,391—31,393. Dec. 15.

Pettigrew and Scudder. Phenol resin condensates. 31,550. Dec. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

20,208 (1918). American Zinc Lead and Smelting Co. Preparing pigment zinc oxide. (122,170.) Dec. 17.

21,352 (1918). Robinson, and Damard Lacquer Co. Phenol formaldehyde condensation products. (136,298.) Dec. 24.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Bashford. Rubber compound. 30,814. Dec. 9.

Conner and Lyttlemore. Process for vulcanising indiarubber. 30,739. Dec. 9.

Willard. Process for devulcanising vulcanised rubber. 30,870. Dec. 9.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATION.

Reuhig and Seemann. Process of tanning skins. 31,065. Dec. 11. (Ger., 2,10,18.)

COMPLETE SPECIFICATIONS ACCEPTED.

7720 (1918). Clark (Chem. Fabr. Worms A.-G.). Tanning animal hides. (136,193.) Dec. 24.

19,902 (1918). Drury. Leather compositions. (135,921.) Dec. 17.

5124 (1919). Dufour and Dufour. Tanning and liming of hides and skins. (125,362.) Dec. 24.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Field, Grinberg, and Grinnell. Treatment of organic matter for fertiliser purposes. 31,584. Dec. 16. (U.S., 27,4,17.)

XVII.—SUGARS; STARCHES; GUMS.

COMPLETE SPECIFICATION ACCEPTED.

20,836 (1918). Martin. Manufacture of lactose or milk sugar. (135,969.) Dec. 17.

XVIII.—FERMENTATION INDUSTRIES.

COMPLETE SPECIFICATION ACCEPTED.

10,315 (1919). Franks. Preserving non-alcoholic beer and other fermentable liquids. (136,448.) Dec. 24.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Ballochmyie Creamery Co., and McCrone. Food product. 31,741. Dec. 18.

Broek, and Broek and Sen. Baking-powder. 31,759. Dec. 18.

Bruff. Preserving peas, beans, etc. 32,030. Dec. 20.

Collins, Hawkins, Sisson, and Travis. Treatment of sewage, trade waste, etc. 31,548. Dec. 18.

Gush. 31,642. See XI.

Hawker. Insecticide. 31,354. Dec. 15.

Hort. Manufacture of protein food products. 30,820. Dec. 9.

Rostados. 31,987. See I.

Spence and Wyllie. Treatment of milk. 30,773. Dec. 9.

Townsend. Milk foods. 30,978 and 30,979. Dec. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

14,970 (1918). Kestner. Food product containing cacao. (136,205.) Dec. 24.

20,079 (1918). Blichfeldt. See XII.

20,197 (1918). Cronstoe and Warnecke. Food-stuffs from marine plants. (121,295.) Dec. 17.

20,216 (1918). Wilton, Hepworth, and Fuessly. Softening, treating, and filtering water. (136,225.) Dec. 24.

I.—GENERAL; PLANT; MACHINERY.

Oiliness and lubrication. R. M. Deeley. Phys. Soc., 28.11.19. Engineering, 1919, 108, 788.

IN recent years the property of "oiliness" has become associated with the presence of unsaturated compounds, which constitute 20–40 of most lubricating oils. Hardy (this J., 1919, 77) concludes "that lubrication depends wholly on the chemical constitution of a fluid," and that "the true lubricant is always a fluid which is absorbed by the solid face." The static coefficients of various oils between metals were measured by allowing three pegs, each 5/32 in. diam., to rest on a flat metal plate which could be rotated. The pegs were attached to a weighted upper disc, which actuated a spindle, to which a spiral spring and recording pointer were attached. The movable disc on which the pegs rested lay in a circular dish which could be filled with oil. To ensure surfaces as clean as possible the rubbing metals were ground in water with carborundum flour, polished, and warmed to remove all traces of moisture. When no lubricant is used the static coefficient increases as the surfaces continue to rub against each other. Such clean surfaces are very sensitive to contaminating influences, e.g. moisture. The static coefficient of friction, and efficiency, obtained for a number of oils tested are shown below, the efficiency being calculated from the formula, $100 - (\text{static coefficient} \times 100) = E$;—

Surface flooded with oil.

Oil. Mineral=M. Animal=A. Vegetable=V.		Mild steel on cast iron.		Mild steel on lead-bronze.*	
		Static coeff.	Efficiency.	Static coeff.	Efficiency.
H.B. clock	M.	0.271	72.9	0.275	72.5
Castor	V.	0.183	84.7	0.159	83.1
Trotter	A.	0.123	87.7	0.152	84.8
Rape	V.	0.119	88.1	0.136	85.8

* The lead-bronze had the composition Cu 53.88, Sn 5.71, Pb 4.0, Zn 4.19, Fe 0.1, Ni 0.12%.

It is interesting to note that the oils which have the smallest coefficient of friction are those which have proved the best lubricants in practice. It would appear that the unsaturated molecules of the lubricant enter into a firm physico-chemical union with the metallic surfaces, forming a friction surface which is a compound of oil and metal. This surface would also appear to be of more than molecular thickness. Thin films of this kind cannot be removed by merely wiping, but must be ground off under water, or a thin layer of metal must be cut off.—C. A. K.

Liquid air; Vessels for the transport and handling of —. E. Moser. Z. angew. Chem., 1919, 32, 365–367.

THE extensive use of liquid air as an explosive in the mining industry in Germany in the latter years of the war led to a great demand for Dewar vacuum vessels. Glass containers were found unsuitable on account of their short life, whilst iron or copper vessels, although more durable, were much less efficient, especially in the smaller sizes. Double-walled vessels of hard glazed, or even unglazed, porcelain, silvered internally, were introduced, and the difficulties of obtaining an airtight seal after evacuation were eventually overcome. Such vessels possessed to a much lesser degree the disadvantages of glass or metal containers and showed an efficiency in the case of the larger transport vessels of 15–25 litres capacity, of 0.6–1.0%

evaporation per hour, whilst the smaller operating containers gave 1.2–2.1 evaporation per hour, compared with double that amount in the case of metal containers.—G. F. M.

PATENTS.

Refrigerating; Process of and apparatus for —. Apeldoornsche Maschinfabriek en Metaalgietterij voorheen Loog Landaal, Apeldoorn, Holland. Eng. Pat. 120,923, 20.11.18. (Appl. 19,084/18.) Int. Conv., 20.11.17.

THE refrigerating liquid is passed through a common pressure-regulating valve, and is evaporated part at high and the remainder at low pressure in separate evaporators with a liquid-vapour separator between the two. The level of the liquid in the separator is controlled by a valve mainly regulated by a float, but the valve opens towards the low-pressure evaporator, so that if the difference between the high and low pressures becomes too great the excess pressure acting on the valve will force it open independently of the float. A single compressor may be used to re-compress the two vapours by admitting the low-pressure vapour during nearly the whole of the outstroke of the piston (e.g. through an automatic inlet valve in the head of the hollow piston), while the high-pressure vapour is admitted through ports in the cylinder wall, which are uncovered by the piston near the outer dead centre only.—B. M. V.

Freezing media. A. J. Instone, London. Eng. Pat. 135,567, 22.11.18. (Appl. 19,244/18.)

A FREEZING mixture for maintaining cold storage chambers at a constant temperature is prepared ready for use by mixing sodium or calcium chloride with a suitable quantity of water, according to the temperature it is desired to maintain; the mixture is cooled nearly to congealing point and sprayed on to a still cooler revolving drum, whence the "ice" is scraped off as it is formed. The "ice" may be compressed into blocks if desired.—B. M. V.

Liquid-cooling apparatus. J. Elger, Chicago, Ill. U.S. Pat. 1,323,587, 2.12.19. Appl., 24.1.18.

THE liquid to be cooled flows from an inlet at the top of a casing down through a perforated plate, around a nest of air tubes, arranged transversely to the current of liquid, and to the outlet at the bottom of the casing. The inlet ends of the air tubes are enclosed in a chamber which has an opening for the inlet of cooling air, also one communicating with the top of the liquid compartment and serving as an expansion vent.—B. M. V.

Cooler for gases and vapours. E. Bergfried, Charlottenburg. Ger. Pat. 313,958, 27.8.16.

THE cooler consists of an outer cylindrical vessel surrounding a cylindrical collecting vessel which extends upwards beyond the top of the outer vessel. Mixed gases and vapours etc. are led into the projecting upper part of the inner vessel, thus allowing condensed liquid to run down into the lower portion, whilst a connecting pipe permits the passage of uncondensed vapours and gases to the annular cooling space surrounding the inner vessel. Uncondensed gases finally pass away by an exit arranged near the bottom of the outer vessel. The upper part of the inner vessel may be provided with a separator whereby heavier liquids such as tar may be collected in the inner vessel, whilst lighter liquids, such as ammonia liquor, are run off by a suitable pipe.—T. St.

Cooling apparatus composed of separate tubes. Bergedorfer Eisenwerk A.-G., Sande. Ger. Pat. 314,124, 1.2.18.

THE apparatus consists of separate tubes arranged

horizontally in a vertical plane and supported at the ends by two vertical members which consist each of one piece only and are bored out lengthwise through the centre. The horizontal tubes pass completely through one vertical boring, alternately at opposite ends, and just to the inner wall of the other vertical boring. The ends of the tubes which pass through the vertical boring are provided with holes in the upper side to afford communication with the vertical boring. The cooling liquid passes left and right through successive horizontal tubes in its passage from the bottom to the top of the apparatus, and the necessity of making water-tight joints is obviated.—T. St.

Heat interchanging apparatus. E. L. Pease, Darlington. Eng. Pat. 135,274, 18.11.18. (Appl. 18,910/18.)

A NUMBER of vertical heat-radiating columns are arranged so that the air or other fluid to be heated passes up them both inside and out. The vertical columns are heated by a hot fluid passing through superposed horizontal tubes in good metallic contact with the vertical tubes. Various diaphragms or concentric tubes may be placed within and between the vertical tubes to increase the radiating surface.—B. M. V.

Grinding, crushing, and pulverising mills. J. F. Wake, Darlington. Eng. Pat. 135,322, 29.11.18. (Appl. 19,770/18.)

A SERIES of loose rings running one within another, the outer diameter of one being less than the inner diameter of the next, are contained in a casing, the axes of all being substantially horizontal. The casing is rotated and grinding takes place between the cylindrical faces of the rings, which may be slightly tapered (say 6°) to the axes.—B. M. V.

Centrifugal attritional pulveriser. J. H. and J. Macartney, Assignors to H. T. Rudisill, Los Angeles, Cal. Reissue 14,764, 2.12.19, of U.S. Pat. 1,253,619, 15.1.18. Appl., 19.8.18.

THE pulveriser comprises two rotary hollow dished members placed face to face so as to form a shallow horizontal circular chamber. The two dished members are slightly separated so as to form a narrow peripheral outlet from the chamber. Material to be pulverised is supplied to the chamber through the hollow shaft, and is thrown against the outer wall of the chamber by centrifugal force. The two dished members rotate in opposite directions.

—W. F. F.

Corrosion in steam turbine plants; Method of preventing. A. Jude, and Belliss and Morcom, Ltd., Birmingham. Eng. Pat. 135,452, 27.8.19. (Appl. 21,041/19.)

OIL is admitted in regulated quantities to some point in the steam service of a turbine plant during the active period of service.—B. M. V.

Precipitating materials from solution; Process and apparatus for. T. B. Crowe, Victor, Colo., Assignor to The Merrill Co., San Francisco, Cal. U.S. Pat. 1,321,985, 18.11.19. Appl., 17.3.17.

THE precipitation process is facilitated by the simultaneous removal of gas from the solution, the presence of such gas interfering with the normal course of precipitation. (See also this J., 1918, 626 A.)—D. F. T.

Air dryer. B. Macfadden, New York. U.S. Pat. 1,322,804, 25.11.19. Appl., 25.3.19.

THREE vertical chambers are arranged side by side and separated by partitions having openings for the passage of horizontal endless belts of ab-

sorbent material. The first chamber is provided with means for projecting sprays of water upwards from the bottom of the chamber, and the third chamber is provided with means for heating and drying the air at the bottom of the chamber. Horizontal baffles are provided in this chamber between the heating means and the lowest endless belt. The first chamber acts as an "eliminating" chamber, the second as a cooling chamber, and the third as a drying chamber; a current of air passes upwards through all the chambers. The belts are arranged so that each is out of alinement with those immediately above and below.—W. F. F.

Solid substances; Methods of obtaining — from solutions carrying the same. G. A. Buhl, Assignor to The G. A. Buhl Co., Chicago, Ill. U.S. Pat. 1,322,875, 25.11.19. Appl., 8.7.15.

THE solution, freed from air, is forced through a coil heated to a temperature above its boiling point, where it is partly volatilised. The solution then passes into an expansion chamber, where it meets a current of air injected at a different angle, so that the two streams are mixed and the liquid evaporated. The vapour is withdrawn from the chamber, and the solid particles are collected.

—W. F. F.

Condensing apparatus. E. W. Christie, Sewaren, N.J., Assignor to Wheeler Condenser and Engineering Co., Carteret, N.J. U.S. Pat. 1,323,013, 25.11.19. Appl., 20.2.17.

A NUMBER of vertical condenser tubes are arranged in a cylindrical casing, and the upper horizontal tube-plate forms the bottom of a superposed reservoir. The condenser tubes terminate in the upper tube-plate, while a short vertical pipe of smaller diameter projects upward from the mouth of each tube into the reservoir, thus allowing a stream of water to flow downward over the inner surface of each condenser tube. A current of air is passed upward through the condenser tubes and short pipes into the atmosphere, and vapour to be condensed is passed through the space surrounding the condenser tubes.—W. F. F.

Filter leaf construction. E. J. Sweetland, Montclair, N.Y., Assignor to United Filters Corporation. U.S. Pat. 1,323,421, 2.12.19. Appl., 7.3.16.

THE filtering fabric is stretched on both sides of a circular ring and is turned over from both sides into a central channel running round the outer periphery of the ring. The ring is surrounded by an outer clamping ring T-shaped in cross-section. The central part of the T-section fits into the peripheral channel to secure the fabric at its edges.

—W. F. F.

Filter press-plate. Enzinger-Werke A.-G., Worms. Ger. Pat. 314,520, 22.4.17.

IN filter-press plates made of rubber or rubber substitute in the form of a corrugated sheet with reinforcing metal insertion fixed in an outer metal frame, the frame, together with a central metal portion, is constructed in one piece with the metal insertion, and the rubber or rubber substitute is fixed in place by a process of vulcanisation.

—L. A. C.

Filter; Plate suction — with continuous discharge for crystalline material. Konsolidierte Alkaliwerke, Westeregeln. Ger. Pat. 314,596, 7.7.16.

IN a plate suction filter the thickness of the layer of dried material ready for removal is adjusted by alteration of the distance between the filter plate and the scraper.—L. A. C.

Drying-machine. H. Parker, Berlin, N.H., Assignor to Brown Co., Portland, Me. U.S. Pat. 1,322,813, 25.11.19. Appl., 13.4.16.

ARTICLES to be dried are conveyed into a drying chamber by a quick-moving conveyor and then transferred to a slow-moving conveyor moving entirely within the chamber. The articles are transferred from the delivery end of the latter conveyor to another part of the quick-moving conveyor, which removes them from the chamber. Supports are provided on the conveyors to receive and hold the articles.—W. F. F.

Dryer. J. T. Le Messurier, Detroit, Mich. U.S. Pat. 1,323,481, 2.12.19. Appl., 31.5.17.

A CYLINDER having its curved surface formed of wire netting is mounted on a concentric perforated pipe, the common axis of both being horizontal. The cylinder is arranged in a casing having a longitudinal discharge conduit along the bottom and a removable receptacle for impurities mounted in the conduit. Air is drawn either from a heating device or from the atmosphere and forced into the pipe and cylinder by a blower at one end. The pipe and cylinder may be rotated alternately in opposite directions.—W. F. F.

Dehydration of moist materials. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin, Ger. Pat. 314,338, 14.7.17.

THE wet material is led from above into a chamber with an outlet at the bottom, the chamber being kept filled during the operation. The dehydrated material is deposited electro-osmotically upon a series of parallel plates inside the chamber resting on supports below and all attached to a horizontal rod above. By manipulation of this rod the plates can be variously inclined to the vertical position, and the distance between contiguous plates will vary correspondingly, being a maximum when the plates stand vertical. During the deposition of material between the plates the latter are turned towards the vertical position to allow for the accumulation of deposited material. When deposition is complete the chamber is emptied of liquid, the plates are then further turned until they are in vertical position, whereby the deposit drops upon the floor of the chamber and can be removed.

—H. J. H.

Liquefied gases; Vessel for transporting and storing — W. Rohn, and W. C. Heraeus G.m.b.H., Hanau, Ger. Pat. 302,532, 27.8.16.

THE actual container is surrounded by several insulating jackets contained one within the other. Each jacket is filled with a gas such that the average temperature prevailing in the jacket is very slightly above the condensation point of the gas, and is packed with so much insulating material that the combination gas plus insulating material yields the maximum insulation effect possible. Each jacket varies in thickness according to the difference in temperature between the inner and outer surfaces of the jacket at different points. Intermediate spaces between the jackets are provided with tubes leading to the outside, whereby vapour arising in the container may be made to circulate through more or less of the spaces before passing away. The rate of evaporation of the contents of the vessel can thus be controlled within a wide range. The vessel is suitable for containing all liquefied gases, including hydrogen.—T. St.

Bakelite; Method of coating autoclaves, vessels of metal or wood, etc., with — Arnstädter Malzfabrik H. & S. Windesheim, and C. ten Doornkaat-Koolman, Arnstadt, Ger. Pats. (a) 304,319, 20.8.16. (b) 305,179, 31.10.17, and (c) 307,699, 29.3.18.

(a) THE surface to be protected is roughened and

coated, by spraying, with bakelite lacquer, and this, before having completely dried, is covered with a layer of bakelite paste. Both layers are dried together, the temperature being first raised gradually to 90° C., and then, after a short time, to about 160° C. The coating is mechanically strong and resistant to acids and alkalis. (b) Protecting parts, such as rivet heads, rivet seams, etc., are covered by means of a brush with a mixture of equal parts of bakelite lacquer or enamel and bakelite paste. Hardening is made to take place under an air-pressure about half an atmosphere above the vapour pressure of the volatile solvent (alcohol) in the bakelite mixture at the respective hardening temperatures. The excess pressure during hardening prevents the formation of blisters in the bakelite coating. (c) With the object of heating uniformly and simultaneously all parts of a vessel which has been coated with bakelite, the vessel is enclosed in a sheet-iron container which is provided at the bottom with a warm-air distributor supplied centrally with a current of warm air.—T. St.

Gases; Automatic means for neutralising — L. Bergfeld, Heidelberg, Ger. Pat. 314,216, 11.10.16.

AN acid solution of known strength is brought in contact with the impure gas to be neutralised and is then added to an excess of a carbonate; the carbon dioxide liberated passes into a float contrivance, which automatically regulates the valve for admitting the liquid for washing the gas. Instead of treating the gas with an acid solution alone, both an alkaline and an acid solution of known strength, the latter in excess, may be employed, and in this case the two solutions are mixed after acting on the gas and then added to the carbonate solution. The motion of the float, instead of directly actuating the inlet valve for the wash liquor, may actuate the inlet and outlet valves of a second vessel provided with a float, which then controls the supply of wash liquor, and, either by adjusting this float or by control of the outlet for the carbon dioxide, the gas may be brought to any desired strength of alkalinity or acidity instead of to the neutral point.—L. A. C.

Mixing liquids and solids in powder or granular form. O. Stier, Heidelberg, Ger. Pat. 314,412, 4.8.17.

THE material is thrown outwards from a rotating disc or fan upon the walls of an enclosing chamber of funnel-shaped construction below so as to collect the material again. The angular velocity of the revolving parts can be varied at will. To avoid segregation of components of differing grades the discs must be suitably constructed and baffles provided to cause the material to be intimately mixed while falling through the air.—H. J. H.

Air or other gases; Compression of — with the addition of other previously compressed gas in the suction stroke. Melms u. Pfenninger Kommanditges., München-Hirschau, and F. Gensheimer, Fiume, Ger. Pat. 311,498, 24.8.17. Addition to Ger. Pat. 304,021.

THE original process is one in which the ordinary air or gas compression cylinder is equipped with an auxiliary cylinder in which additional gas is compressed to an intermediate pressure quite independently. The additional gas is drawn into the main cylinder towards the end of the suction stroke and compressed on the return. The compression in the main cylinder is therefore assisted by the compression in the auxiliary cylinder. In the present patent the apparatus is so constructed that the main piston operates both the compression of the addition gas in the auxiliary compressor and its transference after cooling to the main cylinder.

—H. J. H.

Absorption apparatus; Tubular packing for —. Deutsche Ton- und Steinzeugwerke A.-G., Charlottenburg. Ger. Pat. 314,597, 14.10.16.

STONEWARE tubes for packing absorption apparatus and the like are provided inside with baffles, some of which are inclined so as to form pockets in which liquid collects. A number of layers of the tubes are arranged one above another, and the liquid passing down the apparatus splashes on to the liquid collecting in the pockets and also on to the walls of the tubes, thus effecting good contact between liquid and gas.—L. A. C.

Heating liquids electrically; [Liquid-tight insulating joints in] apparatus for —. G. Bellaviti, Milan, Italy. Eng. Pat. 135,225, 2.11.17. (Appl. 16,017/17.)

High-temperature reactions; Apparatus for conducting —. N. Testrup, Assignor to Techno-Chemical Laboratories, Ltd., London. U.S. Pat. 1,322,652, 25.11.19. Appl., 19.3.18.

SEE Eng. Pat. 115,087 of 1917; this J., 1918, 357 A.

Desiccation of air or gases. G. Claude, Assignor to L'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude), Paris. U.S. Pat. 1,323,014, 25.11.19. Appl., 5.5.14.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Ozonisation of — suspended in non-aqueous media. F. Fischer and H. Tropsch. Ges. Abhandl. zur Kenntnis der Kohle, 1919, II., 160—168. Chem. Zentr., 1919, 90, IV., 842—843.

"SOFT" coal suspended in chloroform was rapidly attacked by ozone with simultaneous chlorination and a considerable increase in weight. The pale

brown reaction product was insoluble in chloroform, soluble in alcohol, less soluble in acetone, acetic acid, and ethyl acetate, sparingly soluble in ether, water, and aqueous acids, but soluble in aqueous alkalis. When suspended in carbon tetrachloride coal was not affected by ozone. In glacial acetic acid a reaction readily occurred and, on evaporation of the acetic acid *in vacuo*, a syrup was obtained from which ether precipitated a light brown strongly acid substance, the solubility of which in water increased with increasing duration of the ozone treatment. The yellow-coloured solution darkened on boiling, and had a strong odour of caramel. By the action of diazomethane on these products compounds of the nature of esters were obtained, insoluble in soda. The substance remaining dissolved in the acetic acid after precipitation with ether yielded a dark reddish-brown mass containing small quantities of oxalic acid. The main portion consisted of readily decomposable coloured substances of strongly acid character, insoluble in organic solvents, which formed with most metallic salts compounds insoluble in acetic acid. The ozonisation of lignite in acetic acid was analogous to that of ordinary coal. Oxalic acid was the primary product of the prolonged ozonisation of coal, but the oxalic acid was itself partially destroyed by ozone.—J. F. B.

Low temperature carbonisation. Tern. Ber., 1919, 52, 1836.

FACTORY plant embodying the features described by Fischer and Glund (this J., 1919, 563 A) was constructed by Tern as early as 1910.—J. C. W.

Ignition-temperatures [of gases]; Determination of — by the soap-bubble method. A. G. White and T. W. Price. Chem. Soc. Trans., 1919, 115, 1248—1264.

THE soap-bubble method for the determination of the ignition-temperature of mixtures of inflammable gases (McDavid, this J., 1917, 1264), in which a soap-bubble containing the vapour is made to impinge on a heated wire coil of known temperature, has been applied to determine the ignition temperatures of certain mixtures of ether, benzene, light petroleum, and hydrogen with air. After careful standardisation the results given by this method were found to be affected by the physical state of the igniting surface and the nature of the material of which it was made. Even the addition of small quantities of the salts used for standardisation purposes altered the results obtained. The ignition-temperature of a particular gas mixture often varied by more than 150° C. as determined by two different coils, and the results indicate that the method is not trustworthy even for comparative purposes.—E. H. R.

Dehydrogenation of hydrocarbons by means of palladium-black. J. Tausz and N. von Putnok. Ber., 1919, 52, 1573—1583.

A METHOD is described by which cyclohexanes can be estimated in mixtures with paraffins, depending on a measurement of the hydrogen liberated when a convenient quantity is circulated over a specially active palladium-black maintained at 270°—300° C. Cyclohexanes are completely converted into benzenes in this way, but the paraffins themselves also produce a little hydrogen, an equilibrium with the olefines being established. The volume of hydrogen produced by the cyclohexanes, however, is nearly 20 times that developed by equal quantities of the paraffins under the same conditions, so that quantitative results are obtained with a fair degree of accuracy if there is more than 1% of the cyclic hydrocarbons in the mixture. As an example of the application of the method, the proof of the presence of cyclohexane in a sample of hexane from American petroleum is given. Whereas 30 c.c. of

synthetic *n*-hexane only gave 338 c.c. of hydrogen, 30 c.c. of the natural oil gave 446 c.c., corresponding to 2.1% of cyclohexane in the sample. (See further, *J. Chem. Soc.*, 1920, ii., 61.)—J. C. W.

Ichthyol oils. Chemical constituents of the bituminous tar oils rich in sulphur. III. H. Scheibler. *Ber.*, 1919, 52, 1903—1910.

THE purification of the crude oil is effected as follows. The oil is heated with soda-lime, whereby it loses its obnoxious odour and becomes paler and more mobile. Then it is washed with dilute sulphuric acid, dried, and heated with sodium in a current of ammonia gas. After this it contains only a small quantity of a ketonic substance, which is destroyed by means of magnesium methyl chloride, and finally the oil is fractionated from sodium. A specimen of crude oil from the south of France gave nearly half its weight of a pleasant-smelling liquid, containing only carbon, hydrogen, and sulphur, all but the highest fractions being colourless. (See also *J. Chem. Soc.*, 1920, i., 74.)

—J. C. W.

Montan wax; Behaviour of — towards ozone. F. Fischer and H. Tropsch. *Ges. Abhandl. zur Kenntnis der Kohle*, 1919, 11., 162—172. *Chem. Zentr.*, 1919, 90, IV., 847.

DARK brown, powdered montan wax, suspended in carbon tetrachloride or glacial acetic acid, was changed to a light brown product by the passage of ozone for a short time, but after prolonged treatment products were obtained which were soluble in dilute alkalis, whereas montan wax itself is saponifiable only on boiling with caustic soda under pressure. Apparently the esters are decomposed by the action of the ozone with the formation of acids. The product obtained from montan wax in carbon tetrachloride was of a waxy nature, and on melting with water the latter showed a weak peroxide reaction; the waxy product could be fractionated by dissolving in alcohol, some of the fractions still containing neutral constituents. Montanic acid, which was isolated from the products of the saponification of montan wax, is also attacked by ozone in the presence of carbon tetrachloride, giving acids of lower molecular weight which form typical soaps with alkalis. When finely-powdered montan wax, suspended in aqueous caustic potash or sodium carbonate, was treated with ozone, no soluble products were formed after 24 hours. On melted montan wax ozone had only a bleaching action.—J. F. B.

PATENTS.

Damp peat; Preparation of — for the manufacture of producer gas. S. C. Davidson, Belfast. Eng. Pat. 135,348, 23.12.18. (Appl. 21,502/18.)

THE moisture in peat as taken from the bog cannot be reduced by mechanical pressure below about 65% without losing large quantities of valuable organic matter along with the expressed moisture. If, however, the peat is thoroughly mixed to a putty-like mass with enough lime to render the mixture distinctly alkaline, say 5%, the oily and resinous matter is coagulated, and the water content may be reduced to 30—35% by mechanical means.—B. M. V.

Peat briquettes; Manufacture of —. A. Pfisterer, Munich. Ger. Pat. 313,892, 19.5.18.

PEAT, humus, or the like is dehydrated by means of cloth-covered press rollers and mixed in a spiral mixer with a meal prepared from weeds or substances containing lichenin. The meal absorbs

water readily, and the mass becomes so stiff that it can easily be pressed into briquettes.—D. W.

Heating flues for combustion of gaseous, vaporous, or dust fuel, or for heating with waste gases. W. E. Davies, Penygraig, S. Wales. Eng. Pat. 135,549, 21.10.18. (Appl. 17,357/18.)

A BAND of flues lies between two parallel stretcher strips or concentrically-curved walls, 3 and 4, of brickwork, and consists of two alternating sub-series of flues, 1' and 1'', forming together a primary series of flues, and a secondary series of flues, 2. Both sets of flues of the primary series may be

used as combustion chambers, or alternate ones may be used as waste heat flues. By a suitable arrangement of primary and secondary flues the gases, after burning in the primary flues, are subdivided and sent in the opposite direction through the secondary flues. The arrangement is intended to withstand the contraction and expansion caused by the reversal during a change-over period in coke-ovens or vertical gas retorts of the regenerative type.—W. P.

Coking process. W. B. Marquard, Easton, Pa. U.S. Pat. 1,323,711, 2.12.19. Appl., 2.1.19.

A BATTERY of coke-ovens is arranged in a series of groups, each containing the same odd number of ovens. The ovens are so charged and discharged that when one oven has completed a run and is being discharged, each of the two ovens immediately adjoining the first has been running for such a time that the sum of these times is together equal to the time taken by the first for a complete run.

—W. P.

Gas producers. D. J. Smith, London. Eng. Pat. 135,319, 28.11.18. (Appl. 19,697/18.)

ALTERNATIVE means are provided for mechanically operating a producer of the type described in Eng. Pats. 120,599 and 121,416 (this J., 1919, 5A) in order that it may be operated independently of the internal combustion engine to which the producer supplies gas. A steam engine mounted on the producer is supplied with steam from a boiler heated by the producer. The steam engine operates the fuel feed, the ash discharge, and the pump for the water supply mechanically and continuously. The air supply may be controlled independently of the steam supply.—W. P.

Gas producers. D. J. Smith, London. Eng. Pat. 135,613, 9.12.18. (Appl. 20,636/18.)

SWIVELLING means are provided at the top of the producer, by means of which the lower fuel-feed tube may be readily displaced and a smoke pipe

or flue caused to register with and cover the fuel-feeding aperture. A slot arranged in some part of the feed pipe is fitted with a glass or other transparent material to enable the fuel to be watched. The invention is applicable more particularly to self-propelling vehicles (see Eng. Pats. 120,599 and 121,446; this J., 1919, 5 A), and the slot is so placed as to be within view of the driver of the vehicle.

—W. P.

Oils and semi-coke; Method for obtaining — from coal in rotating distillation apparatus. F. Fischer, Mülheim. Ger. Pat. 299,191, 14.11.16.

WHILST the coal in the retort is in a plastic condition it is rolled into a compact mass by a massive iron roller which is embedded in the charge. With a cylindrical retort 1.5 m. long and 0.5 m. in diameter, and a roller 0.1 m. in diameter, 15 kilos. of gas coal yields 11.3 kilos. of semi-coke, and 1.5 kilos. of tar oils with a calorific value of 8400 cals. The semi-coke is a transportable, dense, smokeless fuel.—T. St.

Gas producers. H. M. Iversen, Grandrup, Denmark. Eng. Pat. 135,339, 11.12.18. (Appl. 20,654/18.)

MEANS are described for improving the running conditions of producer-gas plant in which the fuel used, such as peat, lignite, or wood, gives rise to a gas which is cleaned only with difficulty. A pumping device forces the gas through a high column of washing fluid, a continuous circulation of gas being maintained by means of a relief valve and pipe.

—W. P.

Coal, water or other gases; Treatment of — and removal of substances contained therein. A. J. Pennington, Manchester, and M. C. Lamb, London. Eng. Pat. 135,577, 25.11.18. (Appl. 19,386/18.)

CONDENSED oils of the pyridine and analogous series, obtained by the destructive distillation of bones or leather, are utilised for removing naphthalene and anthracene from coal gas, or for enriching coal- or water-gas. The carbonaceous residue from the distillation of bones or leather may be treated with steam whilst still in the heated retort for the production of water-gas.—W. P.

Petrols, petroleum, benzols and the like; Process and apparatus for the continuous fractional distillation of —. E. Barbet et Fils et Cie, Paris. Eng. Pat. 117,615, 22.6.18. (Appl. 10,341/18.) Int. Conv., 3.7.17. Addition to Eng. Pat. 9088 of 1914.

IN an apparatus for the continuous fractional distillation of petroleum and the like, of the type described in the chief patent (see Fr. Pat. 468,068 of 1913; this J., 1914, 954), the oil, after dehydration, is heated under atmospheric pressure in a plate column in which the lighter fractions are separated; the residual oil is then distilled under vacuum with multiple (triple) heating effect for separation into different fractions.—L. A. C.

Shales and coals; Treatment [distillation] of —. D. E. Day, Washington, D.C. U.S. Pat. 1,323,681, 2.12.19. Appl., 4.3.18.

HOT flue gases containing not more than a trace of oxygen are utilised for distilling off the hydrocarbon oils from shales. These gases are passed, together with steam, through the material, which is subjected to agitation as it passes through the retort.—W. P.

Shale oils; Process for obtaining — in rotary carbonising retorts. Königl. Bau- und Bergdirektion, Stuttgart, and Zeller und Gmelin, Eisingen. Ger. Pat. 303,803, 1.3.17.

The shale is conveyed continuously to the upper

end of a rotary drum, and in the course of its passage through the drum it is subjected to a gradually increasing temperature and discharged at the other end, the resulting vapours being drawn off in the usual manner. The drum is divided into several sections, each surrounded by a separate heating chamber in which the temperature is raised to the desired degree. The shale is fed to the drum and the gases and the residue are withdrawn all under exclusion of air.—J. F. B.

Purifying liquids. U.S. Pats. 1,323,239, 1,323,251, and 1,323,256. See XIXb.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Cellulose-containing materials [e.g., peat]; Treatment [wet-carbonising] of —. N. Testrup, and Wetcarbonizing, Ltd., London. Eng. Pat. 135,578, 25.11.18. (Appl. 19,389/18.) (See also Eng. Pat. 18,030 of 1914; this J., 1914, 912.)

PEAT is wet-carbonised in suitable apparatus at the lowest economical temperature. The resulting mass is filtered, the press effluent evaporated, preferably in apparatus of the type described in Eng. Pats. 12,462 and 22,670 of 1911 (this J., 1912, 971; 1913, 183), and the acid recovered from the steam or concentrated in the liquor. The recovered acid is added, together with any additional acid required, to a fresh batch of peat. The process results in a great saving of heat.—W. P.

Peat, brown-coal, lignite, sapropel, oil-shales, wood, etc.; Treatment [distillation] of —. C. Francke, Berlin. Ger. Pat. 314,337, 2.11.17.

PEAT or other material is heated in slowly-revolving drums provided at the sides with tubes for leading gas to and away from the drums. The material is first dehydrated and then distilled at temperatures up to 550° C. The drums are heated from below by gas arising from the distillation, after treatment for the recovery of condensable products. Material containing 35% of water can be treated in two hours.—T. St.

Removing gases [from X-ray tubes]; Method of — and apparatus produced thereby. W. D. Coolidge, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,323,836, 2.12.19. Appl., 6.10.16.

III.—TAR AND TAR PRODUCTS.

Nitrobenzene; Determination of the course of the catalytic reduction of —. F. F. Nord, Ber., 1919, 52, 1705—1712.

β -PHENYLHYDROXYLAMINE is known to play an important part in the chemical or electrolytic reduction of nitrobenzene to aniline, and experiments were made to determine whether it is formed immediately during catalytic reduction. *o*-Nitrobenzaldehyde and *o*-nitroacetophenone were shaken with hydrogen and colloidal platinum, and by stopping the reduction after two molecular propor-

tions of hydrogen were absorbed the author was able to isolate anthranil and methylantranil, respectively, these being the internal condensation products of the phenylhydroxylamine derivatives. (Compare J. Chem. Soc., 1920, i., 21.)—J. C. W.

Phthalic anhydride, II. *Melting point of pure phthalic anhydride.* The system: *phthalic anhydride-phthalic acid*. K. P. Monroe. J. Ind. Eng. Chem. 1919, 11, 1116—1119.

PHthalic anhydride made by the catalytic oxidation of naphthalene (Gibbs; this J., 1918, 684A) shows a m. pt. (130° C.) about three degrees higher than that previously recorded. In producing still purer preparations the material was warmed for 5 hours in a vacuum oven at 80° C., and twice sublimed *in vacuo* in the presence of phosphorus pentoxide. No differences were observed by analysis or in the m. pt. of the first and second sublimates. A differential method of titration was devised by Adams in which 0.5 gm. of the sample was dissolved in 50 c.c. of acetone, a few drops of a solution of Bromo-phenol Blue (tetrabromophenolsulphon-phthalein) added, and the solution titrated with *M*/10 normal potassium phthalate solution in 80% alcohol. In the presence of phthalic acid the end-point of the titration is reached when sufficient phthalate has been added to produce the acid phthalate, and a further addition causes the colour to change to indigo-blue. Tested by this method the second sublimate of phthalic anhydride was found to contain less than 0.1% phthalic acid. The melting point was found to be 130.84° C. Mixtures of weighed quantities of pure phthalic acid and pure phthalic anhydride were tested in the same melting-point apparatus and the results plotted in freezing-point curves. It was found that the eutectic temperature (129.74° C.) corresponded to a mixture containing 1.96% of phthalic acid. Owing to the readiness with which this acid decomposes near its melting point into phthalic anhydride and water, direct determinations only afford an approximation to the true m. pt. By graphical extrapolation the m. pt. of pure phthalic acid is indicated to be $208^{\circ}\pm 2^{\circ}$ C.—C. A. M.

Phthalic anhydride, III. *The system: naphthalene-phthalic anhydride.* K. P. Monroe. J. Ind. Eng. Chem., 1919, 11, 1119—1120.

MIXTURES of pure naphthalene (m. pt. 80.05° C.) and phthalic anhydride (m. pt. 130.84° C.) were examined, and the freezing-point curves for the system plotted. The eutectic temperature 64.9° C. corresponded to a mixture containing 29.0% of phthalic anhydride. No evidence was obtained of the existence of solid solutions. (See also J. Chem. Soc., Feb., 1920.)—C. A. M.

PATENTS.

Tar; Removing the — from tar-containing liquids. E. Barbet et Fils et Cie., Paris. Eng. Pat. 120,558, 9.10.18. (Appl. 16,457/18.) Int. Conv., 11.10.17.

AQUEOUS solutions contaminated with tar, e.g., the pyroligneous liquid obtained in the distillation of wood, are treated with organic liquids insoluble in water but capable of readily dissolving the tar, such as cresol or the like. A cylindrical vessel is packed with porcelain balls, quartz, or coke supported by a perforated iron plate placed a short distance above the bottom of the vessel, and an open space is also left at the top of the vessel. Cresol and the aqueous liquid are admitted through the side of the vessel by inlets situated respectively near the top and bottom of the portion filled with packing; the aqueous liquid rises and is scrubbed by the descending stream of cresol. In the open space at the top of the vessel any cresol suspended

in the liquid separates, and a clear solution free from tar is drawn off continuously; cresol containing tar in solution is drawn off from the space below the packing, and is purified by distillation.

—L. A. C.

Wood tar; Extraction of higher fatty acids and other organic acids from —. E. Börnstein, Berlin. Ger. Pat. 314,358, 26.1.17.

The tar is fractionally distilled under reduced pressure and the fatty acids in the fraction boiling at 190°—235° C. at 15 mm. are extracted in the usual manner. The yield varies with the nature of the tar. One kilogram of a crude pine tar yielded approximately 28 grms. of oleic acid, 48 grms. of palmitic acid, and a small quantity of liquid and solid abietic acid; arachidic acid was present in the fractions of higher boiling point.—D. F. T.

Sulphonation of hydrocarbons with sulphur trioxide. C. R. Downs, Cliffside, N.J., Assignor to The Barrett Co. U.S. Pat. 1,321,991, 18.11.19. Appl., 11.6.19.

AN aromatic hydrocarbon whilst in the state of vapour is sulphonated with a gas containing sulphur trioxide.—D. F. T.

Nitro compounds; Process for the production of —. L. J. J. Perruche, St. Gervais, France. U.S. Pat. 1,325,168, 16.12.19. Appl., 19.8.18.

See Eng. Pat. 131,982 of 1918; this J., 1919, 812 A.

Distillation of benzols, etc. Eng. Pat. 117,615. See 11 A.

Purifying liquids. U.S. Pats. 1,323,239, 1,323,251, and 1,323,256. See XIX B.

IV.—COLOURING MATTERS AND DYES.

Alizarin; Action of potassium hypochlorite on — in alkaline solutions. R. Scholl, Ber., 1919, 52, 1829—1836.

ALIZARIN is oxidised by hypochlorite in potassium hydroxide solution, the bluish-black potassium salt of 3,4,3',4'-tetrahydroxy-2,2'-dianthraquinonyl being formed. This is much poorer than alizarin as a mordant dye. When distilled with zinc dust, in an atmosphere of hydrogen, under reduced pressure, it forms 2,2'-dianthryl, and when heated with zinc chloride it loses water and gives 1,1'-dihydroxy-2,2'-dianthraquinonylene-3,3'-oxide. (See further, J. Chem. Soc., 1920, i., 61.)—J. C. W.

Phenols as mordant dyes. R. Möhlau. Ber., 1919, 52, 1730—1731.

PHENOLS which are capable of forming internally complex salts impart more or less fast shades to mordanted wool. 1,8-Dihydroxynaphthalene, α - and β -anthrols, phenanthraquinol, and 1,2-dihydroxynaphthalene-4-sulphonic acid give colours which are fast to air and light, boiling soap solution, or boiling *N*/1 hydrochloric acid. (See further, J. Chem. Soc., 1920, i., 36.)—J. C. W.

Triphenylmethane dyes; Constitution of —. H. Kauffmann. Ber., 1919, 52, 1421—1422.

THE hypsochromic effect of the introduction of a third amino-group in Malachite Green can only be explained on electrochemical lines. By converting Michler's ketone into the chloride and condensing this with *m*-dimethoxybenzene in presence of aluminium chloride a compound is obtained having two methoxy groups in the third nucleus of Malachite Green, namely, 4,4'-tetramethyldiamino-2'',4''-dimethoxytriphenylcarbinol, m. pt. 195° C. Solutions of this white substance have the following

colours; dilute acetic acid, bluish-green; dilute mineral acids, red, becoming bluish-green on dilution; concentrated sulphuric acid, orange.

—J. C. W.

Phthalic anhydride; Condensation of — with phenols in the presence of aluminium chloride. F. Ullmann and W. Schmidt. Ber., 1919, 52, 2098—2118.

HYDROXYBENZOYLbenzoic acid derivatives are prepared in uniformly good yield by the condensation of phenols with phthalic anhydride by means of aluminium chloride in presence of acetylene tetrachloride as solvent. The carbonyl-group of the phthalic anhydride attaches itself for the most part to the carbon atom in the ortho-position to the hydroxyl-group of the phenol. Starting from tetrachlorophthalic anhydride, *o*-hydroxybenzoylbenzoic acid derivatives are almost exclusively obtained which are readily converted by alkalis into xanthone derivatives. Phthalic anhydride and *p*-cresol yield 5'-methyl-2-hydroxy-*o*-benzoylbenzoic acid, $C_6H_4(CH_3)(OH).CO_2C_6H_4.CO_2H$, colourless prismatic crystals, m. pt. 194°—195° C., which is converted by sulphuric acid into 1-hydroxy-4-methyl-anthraquinone, reddish-yellow needles, m. pt. 175° C. 2'-Hydroxy-4'-methyl-5'-chloro-*o*-benzoylbenzoic acid, colourless prisms, m. pt. 205°—206° C., is prepared from *p*-chloro-*m*-cresol and is transformed by sulphuric acid monohydrate into 1-hydroxy-3-methyl-4-chloroanthraquinone, orange-red needles m. pt. 177° C. The latter is converted by *p*-toluidine in the presence of copper powder into 1-hydroxy-3-methyl-4-*p*-toluidinoanthraquinone, bluish-violet needles, m. pt. 191° C. The chlorine atom can be replaced by the hydroxyl-group by treatment with sulphuric and boric acids at 150°—160° C., whereby 1,4-dihydroxy-2-methylanthraquinone (2-methylquinizarin), carmine-red needles, m. pt. 177° C., is formed. 1-Hydroxy-3-methyl-4-toluenesulphonaminoanthraquinone, yellowish-brown needles, m. pt. 213°—214° C., is obtained by heating the hydroxymethylchloroanthraquinone with potassium acetate, *p*-toluenesulphonamide, and copper acetate in amyl alcoholic solution and is hydrolysed to 1-hydroxy-3-methyl-4-aminoanthraquinone, violet needles, m. pt. 257°—258° C. When heated with potassium and copper acetates in the presence of naphthalene the hydroxymethylchloroanthraquinone yields 1-hydroxy-3-methylanthraquinone, m. pt. 178° C. The condensation of *p*-cresol with tetrachlorophthalic anhydride gives 2'-hydroxy-5'-methyl-3,4,5,6-tetrachloro-*o*-benzoylbenzoic acid, m. pt. 232°—235° C. according to the rate of heating, which is quantitatively transformed by alkali carbonate or hydroxide into 2-methyl-5,6,7-trichloroxanthone-8-carboxylic acid, colourless prismatic needles, m. pt. 263°—266° C. Under similar conditions *m*-cresol gives 2'-hydroxy-4'-methyl-3,4,5,6-tetrachloro-*o*-benzoylbenzoic acid, pale yellow plates, m. pt. 226°—228° C., which yields 3-methyl-5,6,7-trichloroxanthone-8-carboxylic acid, long, colourless prismatic needles, m. pt. 254°—256° C. (decomp.). 2'-Hydroxy-3'-methyl-3,4,5,6-tetrachloro-*o*-benzoylbenzoic acid, yellow rhombic plates, m. pt. 222°—225° C. and 4-methyl-5,6,7-trichloroxanthone-8-carboxylic acid, colourless prismatic needles, m. pt. 270°—273° C. (decomp.) are successively prepared from *o*-cresol. Phenol yields 2'-hydroxy-3,4,5,6-tetrachloro-*o*-benzoylbenzoic acid, colourless, shining leaflets, m. pt. 216°—218° C. and 5,6,7-trichloroxanthone-8-carboxylic acid, colourless prismatic needles, m. pt. 261°—264° C., whilst β -naphthol gives 2'-hydroxy-3,4,5,6-tetrachloro-2- α -naphthoylbenzoic acid, yellowish rhombic plates, m. pt. 214°—217° C. and 4',5',6'-trichloro-1,2-naphthoxanthone-1'-carboxylic acid, needles, m. pt. 273°—275° C. (decomp.). All the recorded m. pts. are "corrected."

—H. W.

PATENT.

Azo dyestuffs dyeing on mordants and process of making same. C. Jagerspacher, Assignor to Society of Chemical Industry in Basle, Switzerland. U.S. Pat. 1,323,285, 2,12.19. Appl., 14.5.19.

DYESTUFFS prepared by combining 1,8-dihydroxynaphthalenesulphocarboxylic acids with aromatic diazo compounds which do not contain a hydroxyl group in the *o*-position to the azo-group dye wool, in an acid bath, red to blue tints. On subsequent chroming of the dyed wool, or by printing the colours together with chromium mordants on cotton, fast blue to black shades are produced.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose; Modification of — in the beetling process. C. F. Cross. J. Soc. Dyers and Col., 1919, 35, 271. (See also this J., 1919, 7A.)

NORMAL bleached cotton cloth was damped and beetled continuously in a layer 2 ins. thick until the fibre was tendered up to the point of destruction. In this treatment considerable heat was developed up to a maximum temperature of 200° C. The following results were obtained on examination of the fibre under the action of sodium hydroxide solution of 17.5% concentration. Original cotton:— α -cellulose, 99.7%; β -cellulose, 0.8%. Half-tendered portion:— α -cellulose, 92.3; β -cellulose, 4.9; hygroscopic moisture, 3.6%. Fully tendered portion:— α -cellulose, 78.0; β -cellulose, 16.2; hygroscopic moisture, 3.3%. The results show that the destroyed fibre was not identical with the fine powder previously described.—J. F. B.

Cellulose; Colloidal —. Investigations on the dissociation of mordant salts by cellulose. C. G. Schwalbe. Z. angew. Chem., 1919, 32, 355—357. (See also this J., 1919, 858A.)

In the manufacture of "pergamyn" (greaseproof) papers, Mitscherlich wood pulp is beaten in the hollander until it acquires a slimy condition. This type of wood cellulose is characterised by a relatively high cupric-reducing value, and if hydrocellulose or oxycellulose be similarly beaten in the hollander, the colloidal condition is reached far more quickly than in the case of cellulose itself. Moreover, if a normal cotton cellulose with low cupric-reducing power be beaten, the conversion into a colloidal condition takes very much longer, and when the modification is ultimately effected the cupric-reducing power of the product is considerably higher than that of the original material. Hence it appears probable that the formation of colloidal cellulose by prolonged beating is connected with the production or presence of hydrocellulose and oxycellulose. The slimy modifications of cellulose exhibit typical colloidal properties; they dry up in the air to tough, horny masses which swell out again considerably in an atmosphere saturated with moisture, but if the colloid be dried at a high temperature it becomes irreversible, and the tendency to absorb moisture is strongly reduced. The gelatinous celluloses produced by mechanical treatment are different from those produced by the swelling action of concentrated solutions of acids, alkalis, or salts. The latter "mercerised" celluloses are characterised by the formation of a blue compound with iodine reagents, whereas the mechanically prepared colloids have little affinity for iodine. On the other hand, the colloids produced by prolonged beating have a very pronounced influence in promoting the dissociation of aluminium sulphate with fixation of aluminium hydroxide, and this property is enhanced in the case of colloids produced by the

mechanical treatment of hydrocellulose or oxycellulose. The dissociation of neutral salts which takes place during the steaming or ageing of mordanted goods and the fixation of metallic bases and dye-stuffs are probably intimately connected with the formation of hydrocellulose or oxycellulose or both. The conditions of the reaction have considerable influence on the result, and optimum effects are obtained by restricting the proportion of water vapour present. The utility of the reaction, however, is limited by the danger of tendering the fibre. In order to avoid this it may be possible to employ external applications of artificially-prepared hydrocellulose or oxycellulose or to utilise the natural hemicelluloses, in which case it is to be noted that the colloidal properties of these substances can be developed by pressure, whereby a gelatinous modification is produced. Possibly the merits of the jigger and padding machine methods of dyeing may be attributed to this influence of pressure. Lastly, it is pointed out that the presence of gelatinised hydrocellulose or oxycellulose has an important influence upon the wetting of the goods. Goods which have been mordanted with metallic salts are difficult to wet, owing to the formation of an irreversible condition of the colloid in combination with the metallic hydroxide, similar to the effect produced by hot ironing of the colloidal cellulose in the absence of metallic mordants.—J. F. B.

Wood; Constituents of — which give colour reactions. III. H. Wichelhaus. Ber., 1919, 52, 2054—2056. (Compare this J., 1916, 1151; 1918, 129 A.)

THE active constituents have been removed from the distillates by extraction with ether and purified by distillation under greatly reduced pressure; two fractions, b. pt. 88° C. at 0.4 mm. and 95° — 105° C. at 0.4 mm., are obtained together with formic acid. Analyses of the fractions give results in agreement with those required by the formulæ, $C_{14}H_{22}O_8$ and $C_{16}H_{22}O_{11}$, respectively, which are simply related to the formulæ of brasilin and hamatoxylin.—H. W.

Gloss of papers. Kieser. See XXI.

PATENTS.

Vegetable fibrous materials; Treatment of — and production of detergents. The Amber Size and Chemical Co., Ltd., London, and C. Weygang, Maidenhead. Eng. Pat. 135,210, 15.10.18. (Appl. 16,825/18.)

STRAW, wood, flax, jute, or the like, is boiled with water containing a mixture of 1 part of an alkali metal compound of low alkalinity, such as a sesquicarbonate, or "Crex," and 1 to 4 parts of calcium carbonate. The relative proportions of the constituents, the strength of the solution, and the time of boiling are varied according to the product desired; thus, if straw is boiled for 5—10 hours in an open vessel with water containing 6—8% of a mixture of 1 part of the alkali compound and 2 parts of calcium carbonate, the fibre is reduced to a gelatinous condition and gives a horny and more or less transparent paper, but if the proportions of the mixture are halved the fibres are left more distinct, but are softer and tougher than the untreated fibres. The liquor obtained after separation of the fibrous material may be utilised as such in the manufacture of soap, or it may be allowed to stand and the sediment, either in a pasty condition or dried and ground, may be added to soap, to which it imparts increased detergent properties.—J. A. C.

Wool; Process of treating [cleaning] —. H. Y. McBride, Artesia, N. Mex., Assignor to The United States Wool Co., Denver, Colo. U.S. Pat. 1,323,611, 2.12.19. Appl., 15.1.17.

IS the process of cleaning wool, dry pulverised cleaning material and a suitable proportion of dry pul-

verised lubricating material are applied to the wool, which is then combed in the presence of a further quantity of similar cleaning material. A quantity of dry pulverised lubricant is then applied to the fibre. The cleaning operation is conducted in progressive stages in which the cleaning material moves in counter-current to the fibre.—S. S. A.

Hop bark; Process for obtaining fibre from —. U. Dammmer, Berlin-Dahlem. Ger. Pat. 299,164, 27.1.17.

THE stripped bark is steeped for a short time in a highly-dilute solution of lactic acid; it is then transferred to pure water and the fibre is separated from the bark. The mass surrounding the fibre is converted by the lactic acid into a form in which it can be easily removed by water.—J. F. B.

Willow or poplar bark; Process for utilising —. J. Kersting, Weine. Ger. Pat. 300,611, 29.2.16.

GREEN willow or poplar wood is steamed at 150° — 180° C., the bark is stripped, shredded, and boiled with water under pressure, whereby a tanning liquor is obtained, and the bark is further shredded, washed, and rolled in order to prepare the fibre for spinning.—J. F. B.

Fibre plants; Process for treating —. E. Einstein, Hechingen. Ger. Pat. 305,633, 13.3.17.

THE plants are boiled for a short time in a nearly saturated solution of caustic alkali, with or without pressure, and the treatment is repeated if necessary. Plants which are easily treated, for instance, nettle stems or isolated bast, are given first a preliminary boil in spent liquor and then treated at about 100° C. in a caustic soda lye containing about 1 kilo. NaOH to 1 litre of water for 15—30 minutes. The material is squeezed or rinsed and boiled with several changes of water. The treatment is repeated until a spinning fibre sufficiently clean and colourless is obtained. In the case of fibrous materials more difficult to treat, such as broken hops or rushes, a caustic soda bath saturated at a higher temperature is used, and solid caustic soda is added during the boiling to replace that which has been consumed; the first boiling may be prolonged to 1—2 hours.—J. F. B.

Tree bark; Process for obtaining textile fibre from —. F. Kniebel, Rühn. Ger. Pats. (A) 305,655, 12.10.17, and (B) 307,721, 18.11.17.

(A) POPLAR twigs are boiled, the bark is stripped, boiled with sodium carbonate, washed, centrifuged, shredded by carding in the moist condition, dried, and spun. (B) Instead of poplar twigs, the twigs and branches of linden, willow, and other trees may be treated in the above manner.—J. F. B.

Tree barks; Manufacture of light-weight millboards from —. O. Zimmermann, Berlin-Lichterfelde. Ger. Pat. 305,697, 16.8.17.

TREE bark is ground in a kind of bone mill, beaten in a hollander, and delivered to a strainer, from which the beaten stuff, diluted with water, passes to a millboard machine, on which it is worked up as the middle layer of the finished board. The bark pulp has a certain colouring power for boards made of waste papers, and yields a board of low specific gravity.—J. F. B.

Textile goods; Process for rendering — water-repellent. Farbenfabr. vorm. F. Bayer and Co., Leverkusen. Ger. Pat. 307,111, 16.12.16.

THE fabrics are impregnated with an aqueous emulsion of montan wax prepared by the aid of alkalis. Montan wax is heated and stirred with a 1% solution of sodium hydroxide to form a permanent, non-separating emulsion, suitable for impregnating without weakening the fibre.—J. F. B.

Oxycellulose free from saline matter; Production of — R. Adler, Vienna. Ger. Pat. 314,311, 9.1.14.

SALTS of oxycellulose are mixed with an inert solvent such as methyl or ethyl alcohol, ethyl or amyl acetate, or acetone, and then treated with an acid of which the corresponding metallic salt is soluble in the solvent used; the free oxycellulose is then washed with more of the solvent and dried at a low temperature. The dried product forms a hard transparent mass which is completely soluble in alkalis and can be used for the preparation of cellulose solutions.—D. F. T.

Sulphate pulp; Recovery process in the manufacture of — E. Olsson, East Angus, Quebec. U.S. Pat. 1,322,043, 18.11.19. Appl. 16.8.18.

SODIUM bisulphate is added to the washing liquid ("black liquor?"), the solution is evaporated, and the residue burned.—C. A. K.

Paper pulp; Process of colouring — with sulphur dyestuffs (thiophor-dyestuffs). C. Jäger, G.m.b.H., Düsseldorf. Ger. Pat. 298,826, 17.3.16.

A COLLOIDAL suspension of a sulphur dyestuff, which may be prepared by boiling the dyestuff with Turkey-red oil or "monopol oil," is reduced by an alkaline solution of hydrosulphite, and the leuco compound so obtained is added to the pulp in the course of manufacture; it has a strong affinity for the pulp and the colouring, re-oxidation, and fixation take place in the cold, the pulp being sized at the same time. If hydrogen peroxide be used as the oxidising agent and aluminium sulphate as the fixing agent, very brilliant shades are obtained.—J. F. B.

Wood or other cellulose materials; Manufacture of cellulose from — Zellstoffabrik Waldhof, and H. Clemm, Mannheim, and R. Willstätter, Munich. Ger. Pat. 304,214, 20.10.16.

THE material is treated with liquid or gaseous reagents at a comparatively moderate temperature, but at a greatly increased pressure created not entirely by heating the liquid, but largely by forcing in a liquid or gas. The digestion may be carried out under a pressure of 50 atm. in order to obtain a good penetration of coarser material and a more complete digestion. The avoidance of high temperatures while maintaining all the advantages of a high pressure gives a cellulose fibre in a better state of preservation than by the usual process, and the constituents of the spent liquors are less profoundly decomposed, so that the by-products may be more advantageously utilised. The process may also be utilised in the saccharification of cellulose.—J. F. B.

Pyroxylin solvent and composition containing the same. E. M. Flaherty, Parlin, N.J., Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,323,624, 2.12.19. Appl., 5.3.18. Renewed 26.9.19.

A PYROXYLIN composition is dissolved in a mixture of butyl acetate, xylol, and butyl alcohol.—S. S. A.

Pyroxylin; Process of treating — and products thereof. A. Schwarzman, Assignor to S. Kellogg and Sons, Inc., Buffalo, N.Y. U.S. Pat. 1,323,792, 2.12.19. Appl., 29.3.19.

To reduce the inflammability of pyroxylin it is treated with halogen until a substantial amount of the latter is chemically combined.—S. S. A.

Cellulose preparations; Process for purifying and improving —. Elektra-Osmose A.-G. (Graf Schwerin Ges.). Ger. Pat. 305,118, 18.3.17. Addition to Ger. Pat. 296,053 (this J., 1917, 593).

THE process is conducted in the presence of substances with an alkaline reaction, for which purpose

small additions of ammonia or sodium hydroxide are suitable. Owing to the continuous presence of hydroxyl ions in the intermediate chamber the migration of the acid impurities is greatly accelerated, so that the purification of the materials can be effected in a much shorter time than without such additions. In the course of the treatment the added substances are themselves removed by the electric current, so that products, such as nitrocellulose, are obtained which are free from both acid and alkaline residues.—J. F. B.

Wood cellulose as a substitute for cotton in chemical industries; Manufacture of highly-purified — W. Schacht, Weissenfels. Ger. Pat. 306,366, 14.3.18.

WOOD cellulose prepared by any of the alkaline processes is further digested by boiling with a sulphite solution. The gelatinous substances (hemicelluloses) which are present in soda-wood pulps are removed by the sulphite treatment, and a highly-purified cellulose is obtained, suitable for use as a substitute for cotton in the chemical and paper-making industries.—J. F. B.

Beating and refining engine; Continuous — for use in the manufacture of paper and the like. T. H. Nash, St. Paul's Cray. Eng. Pat. 135,733, 5.3.19. (Appl. 5479/19.)

A SERIES of beating rolls is mounted in a common trough, the bottom of which is so constructed that the pulp or the like gradually ascends whilst passing under the rolls, and is thereafter returned, by pipes or ducts passing through or beneath the bottom, to an opening in the feed plate. An adjustable deflector is fitted near each opening in the feed plate, by means of which the stream of pulp passing from the feed plate may be narrowed, thereby causing the pulp to pass under the rolls a greater number of times.—S. S. A.

Paper and other absorbent materials; Process for sizing —. Holzverkohlungs-Ind. A.-G., Konstanz. Ger. Pat. 303,925, 24.2.16.

ALKALINE solutions or suspensions containing products of the condensation of tar and aldehydes in the presence of alkalis are added to the paper pulp, and the sizing constituent is precipitated by substances with an acid reaction. Example: Beechwood tar is freed from acetic acid and other acid substances and then condensed with formaldehyde in the presence of alkali. The quantity of formaldehyde is so chosen that it is not sufficient to condense all the tar constituents. Paper can be satisfactorily sized with 1% of the product. The product may also be mixed with bakelite resins soluble in alkalis.—J. F. B.

Paper; Process of sizing —. H. Wandrowsky, Berlin. Ger. Pat. 314,146, 30.11.17.

SIZING is effected by means of the natural resins present in wood cellulose by adding substances having an alkaline reaction to the wood pulp during the beating, in order to convert the resin into a resinate, which is then precipitated on the fibre by aluminium sulphate.—J. F. B.

Straw paper and straw-board factories; Utilisation of the spent time liquors from —. R. Adam, Bremen. Ger. Pat. 314,054, 28.3.17.

THE spent liquor separated from the straw pulp by mechanical means is evaporated, dried, and the residue submitted to destructive distillation. The products resemble those from the distillation of wood and comprise acetone and methyl alcohol.—J. F. B.

[Paper] coating machines. C. W. Mayer, Rochester, N.Y., U.S.A. Eng. Pat. 135,678, 6.1.19. (Appl. 397/19.)

Conditioning of textile fibres and other materials; Moistening or —. H. Smethurst, Hollinwood. Eng. Pat. 135,748, 5.4.19. (Appl. 8634/19.)

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Anthocyanins and certain related compounds; The tinctorial properties of some —. A. E. Everest and A. J. Hall. J. Soc. Dyers and Col., 1919, 35, 275—279.

THE anthocyan pigments give beautiful shades fast to light, but not fast to washing, and very sensitive to acids and alkalis. Both the anthocyanins (glucosides) and the anthocyanidins (products of hydrolysis) derived from them dye full shades on tannin-mordanted cotton from a faintly acid bath, but on wool mordanted with a metallic oxide the anthocyanins have scarcely any tinctorial power, whereas the corresponding anthocyanidins dye readily. Thus it would appear that the affinity for the tannin-mordant is due to the pyran ring containing basic oxygen, and that the affinity for the metallic mordants is due to the phenolic hydroxyls of the catechol nucleus, which, in the form of the glucosides, are masked by the sugar residues. Experiments with violamin chloride showed that in the change from the coloured form to the colourless pseudo-base the tinctorial properties are entirely extinguished. Several synthetic compounds have been prepared and studied, among them 2-phenyl-benzopyryronium chloride, the parent substance of the anthocyanins; full dyeings of straw-yellow shade were obtained with this substance on a tannin mordant in a bath made nearly neutral with alkali or sodium acetate. Like the natural compounds of the anthocyan series, this substance also tends to pass into a colourless pseudo base in dilute aqueous solution. In the case of pure pigments the dye-bath is made up by dissolving 0.0025 gm. of the pigment in a mixture of 10 c.c. of alcohol and 40 c.c. of water and the solution acidified by five drops of 10% sulphuric acid. In this bath 1 gm. of wool or mordanted cotton is dyed at 25°—30° C. When extracting the colouring matter from flower petals, fruit, or fruit skins the same procedure may be followed, or else the materials may be extracted with alcohol containing the acid and the solution poured into water to make the bath.—J. F. B.

Colloidal cellulose. Schwalbe. See V.

PATENTS.

Woollen goods; Process for increasing the resistance to wear of dyed —. L. Cassella und Co., Frankfort. Ger. Pat. 303,231, 17.10.16.

THE material is impregnated with chromium salts, e.g. chromium acetate, and then steamed or otherwise treated so as to separate chromium hydroxide. The quantity of chromium should be at least 1% Cr₂O₃ referred to the dry material.

Colouring paper pulp. Ger. Pat. 298,826. See V.

[Chrome] leather waste. Eng. Pat. 115,421. See XV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Ammonia; Synthesis of — at very high pressures. G. Claude. Comptes rend., 1919, 169, 1039—1041.

HAVING previously shown the possibility of using very high pressures in industrial processes (this J., 1919, 885 A), the author has studied the synthesis of

ammonia at pressures ranging up to 1000 kilos. per sq. cm. At this pressure and at a temperature of 536° C. the yield of ammonia exceeds 40% as against the 13% yield at the pressures used by the Badische Anilin Co. At these high pressures the temperature range within which a reasonable reaction velocity is obtained is 500°—700° C. At a temperature of 600° C., with the catalyst commonly used, 6 grms. of ammonia at a concentration of 25% is obtained per gram of catalyst per hour, as against 0.5 gram at a concentration of 6% obtained by the Badische Anilin Co.—W. G.

Ammonia gas equilibrium; Calculation of the —. E. Maurer. Z. anorg. Chem., 1919, 108, 273—302.

A COMPARISON is made of the results obtained for the nitrogen-hydrogen-ammonia equilibrium at different temperatures and pressures by Haber and Le Rossignol (this J., 1913, 134), and Jost respectively. It is concluded that the results of these experimenters are in full agreement, and, further, that the work of Jost (Z. anorg. Chem., 1908, 57, 414; J. Chem. Soc., 1908, ii., 362, 761) was a sufficient scientific foundation for the technical synthesis of ammonia.—E. H. R.

Ammonia oxidation; Heat of reaction of —. G. B. Taylor. J. Ind. Eng. Chem., 1919, 11, 1121—1123.

A GENERAL formula for calculating the theoretical heat of reaction for any mixture of ammonia and air, at any conversion efficiency is based upon the following equations:—

- (1) $4\text{NH}_3 + 5\text{O}_2 = 4\text{NO} + 6\text{H}_2\text{O} + 214,200 \text{ cal.}$
- (2) $4\text{NH}_3 + 3\text{O}_2 = 2\text{N}_2 + 6\text{H}_2\text{O} + 300,600 \text{ cal.}$

The optimum temperature for the catalytic oxidation of ammonia to nitric acid has been shown to exceed 800° C. Both calculation and experiment have shown that the heat developed in the reaction is insufficient to maintain the optimum temperature for the catalysis, and a source of external energy is therefore necessary. Experiments have shown that electric heating, pre-heating the ammonia-air mixture, or enriching the current of ammonia and air with oxygen give equally satisfactory results.

—C. A. M.

Nitrous anhydride; Properties of — pure or in solution in nitrogen peroxide. G. Baume and M. Robert. Comptes rend., 1919, 169, 968—970.

A STUDY of the melting-point and vapour pressure diagrams of the system N₂O₄—N₂O gives the b. pt. of pure nitrous anhydride as -27° C. at 760 mm. It is not possible to distil it in a vacuum because of the immediate formation of an atmosphere of nitric oxide at temperatures at which distillation is practicable. (See further J. Chem. Soc., 1920, ii., 31.)—W. G.

Ferrieyanide and ferrocyanide; Estimation of —. I. M. Kolthoff. Pharm. Weekblad, 1919, 56, 1618—1626.

FERRICYANIDE can be readily estimated iodometrically in acid solutions, and accurate results are obtained. Rupp's method for the estimation of ferrocyanide in which an excess of iodine and sodium acetate or sodium bicarbonate are added to the ferrocyanide solution, and the excess iodine titrated with thiosulphate after one hour (this J., 1902, 1099) gives incorrect results. The author gives a theoretical interpretation of the iodometric estimation of ferri- and ferrocyanide. (See also this J., 1918, 122 A.)—W. J. W.

Lithium silicate. K. A. Vesterberg. Medd. K. Vetenskapakad. Nobel-Inst., 1919, 5, No. 30, 1—9.

AMORPHOUS silicic acid, which has been dried at 100° C., dissolves slowly in a fairly concentrated solution (approx. 2N) of lithium hydroxide at

ordinary temperatures, giving finally a solution containing 3.4 mols. SiO_2 to 1 mol. Li_2O . Thus lithium behaves similarly to potassium and sodium in giving soluble silicates containing a large excess of acid over the base (compare *J. Chem. Soc.*, Feb., 1920). In warm lithium hydroxide solution, however, silicic acid is almost insoluble, the acid being transformed into a practically insoluble lithium silicate. Lithium metasilicate occurs in two modifications, the one easily soluble and the other almost insoluble. The latter, which has the formula $\text{Li}_2\text{SiO}_3 \cdot \text{H}_2\text{O}$, is obtained as a white granular precipitate when a fairly concentrated solution of sodium metasilicate is mixed with the equivalent quantity of lithium chloride, lithium hydroxide added in approximately $N/1$ concentration, and the solution heated for a short time at 80° – 90° C. It can also be obtained by dissolving silicic acid, which has been dried at a temperature not higher than 100° C., in twice the theoretical amount of $2N$ lithium hydroxide solution at ordinary temperature, and then heating the solution for a short time at 80° C.—T. S. P.

Radioactivity of uranium. C. Staehling. *Comptes rend.*, 1919, 169, 1036–1039.

OXIDES of uranium prepared from uranyl nitrate or ammonium uranate, after suitable preliminary purification, showed a lowering in their non-penetrating activity over the period Jan., 1913, to Nov., 1919, equal to from 1 to 30.7%, the curves indicating that half the lowering took place in 6.2 months. A black-green oxide, which showed a lowering from 5.95 to 4.64%, was dissolved in nitric acid and the nitrate again calcined giving the black oxide; the activity of the latter was 5.90%, and the conversion of this black oxide into the green oxide through ammonium uranate did not appreciably lower its restored activity. Renewing the surfaces of the discs carrying the test specimens did not modify the activities observed.—W. G.

Zirconium monoxide; Question of the existence of —. R. Schwarz and H. Deisler. *Ber.*, 1919, 52, 1896–1903.

THE black powder obtained by reducing zirconium dioxide with magnesium does not contain a monoxide, but is a mixture of free metal and dioxide. The more sudden the reduction (firing by thermite) the greater is the proportion of free metal in the product. (See further *J. Chem. Soc.*, 1920, ii., 42.)—J. C. W.

Chlorine and hydrogen; Interaction of —. Influence of mass. D. L. Chapman and J. R. H. Whiston. *Chem. Soc. Trans.*, 1919, 115, 1264–1269.

BODENSTEIN and Dux have concluded from their experiments (*Z. physik. Chem.*, 1913, 85, 297) that the reaction is of the second order, the velocity being proportional to the square of the concentration of the chlorine. The present authors cannot confirm this result, for they find that, within wide limits of concentration of the interacting gases, the rate of formation of hydrogen chloride is given by the expression $\frac{k \cdot I \cdot [\text{Cl}]}{[\text{O}]}$ where k is a constant, and I the intensity of the radiation. The rate of interaction with moist gases is found to be almost independent of the pressure, instead of proportional to the pressure, as it would be if the result of Bodenstein and Dux were correct. The results here recorded are in agreement with the theory of the reaction put forward by Chapman and his co-workers (this *J.*, 1909, 1196; 1913, 424).—E. H. R.

Silicon hydrides. VII Protosiloxane. A. Stock and K. Somieski. *Ber.*, 1919, 52, 1851–1860.

COMPOUNDS of the formula SiH_2Hal_2 react with water to form polymerides of protosiloxane. The

unimolecular form, $\text{O} \cdot \text{SiH}_2$, is obtained as a gas by the interaction of water vapour and the dichloride in a large flask under reduced pressure, but the tendency to polymerise is so great that the apparatus must be clean and smooth. On condensation, the gas polymerises at once, to benzene-like liquids, soluble in benzene, $(\text{SiOH})_n$ etc., and insoluble solids. All polymerides react with sodium hydroxide to give hydrogen and sodium silicate. (See further, *J. Chem. Soc.*, 1920, ii., 31.)—J. C. W.

Diamond; Experiments on the artificial production of —. C. A. Parsons. *Phil. Trans.*, 1919, A 220, 67–107.

BAKERIAN Lecture, 1918, containing a full account of work already described before the Institute of Metals (this *J.*, 1918, 300 A).

PATENTS.

Sulphuric acid; Manufacture of —. H. Royal-Dawson, Huddersfield. Eng. Pat. 135,359, 4.1.19. (Appl. 265/19.)

To facilitate the horizontal movement of gases in sulphuric acid chambers, columns of packing material are fixed in the chambers, the surfaces being kept wet by water sprays or steam jets. The chamber top may contain sunken channels or reservoirs for the feed acid, with inlets to the chambers immediately above the baffle columns.—W. J. W.

Ammonia; Oxidation of —. H. E. F. Goold-Adams, London, J. R. Partington, Lostock Grahm, and E. K. Rideal, London. Eng. Pat. 135,224, 7.7.17. (Appl. 9853/17.)

A CATALYST for the oxidation of ammonia consists of nickel or "other non-platinum metal" in the form of gauze or perforated plate, which may be covered with a layer of nickel oxide or other catalytic substance.—W. J. W.

Nitric acid; Continuous concentration of dilute —. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 297,901, 13.4.16.

A MIXTURE of concentrated sulphuric acid and dilute nitric acid flows down a tower packed with acid-resisting material, such as glass, quartz, or the like, and passes into an externally heated still or retort. An outlet siphon tube is attached to the retort at a suitable height, e.g., half way up the side. The mixture of acids is so adjusted that nitric acid of the required strength distils over, and about 70% sulphuric acid flows out of the retort.—L. A. C.

Nitrous sulphuric acid; Denitration of waste —. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 297,902, 11.7.16.

WASTE nitrous vitriol is concentrated to about 56° B. (sp. gr. 1.635); the greater part of the nitric oxide is then removed by passing a stream of air through the hot acid, and the last traces are eliminated by treating a stream of the acid with a counter-current of sulphur dioxide.—L. A. C.

Nitric acid; Manufacture of highly concentrated — from dilute nitric acid. Deutsche Gasglühlicht-A.-G. (Auerger.), Berlin. Ger. Pat. 299,681, 1.12.16.

NITRIC acid of less than 69% strength is concentrated to above that strength by distillation with

approximately 78% sulphuric acid; the partially concentrated acid is then distilled in an apparatus fitted with a fractionating column to produce an acid of high concentration. Complete separation of the dilute nitric acid from the mixed acids remaining in the still is effected in a separate apparatus, and both the dilute nitric acid thus obtained and the sulphuric acid, after concentration to about 78% strength, are returned to the vessel in which the first stage of the concentration takes place.—L. A. C.

Ammonia; Method of purifying gases intended for synthetic production of —. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude, Paris. Eng. Pat. 129,637, 4.10.18. (Appl. 16, 986/19.) Int. Conv., 15.2.18.

Is the purification by means of heated palladium-asbestos of mixtures of nitrogen and hydrogen intended for the synthesis of ammonia under very high pressures (500—2000 atm.; see Eng. Pat. 130,086; this J., 1919, 718A), the same "hyper-pressure" is used for eliminating the water formed in the purification process. Two temperature exchangers are employed, one of which brings the gases to the temperature of combination in the presence of the palladium-asbestos, while the other cools the gases to a temperature near the freezing point of water.—W. J. W.

Potassium chloride; Manufacture of —. E. E. and P. C. Dutt, Jubbulpore. Eng. Pat. 135,246, 18.10.18. (Appl. 17,080/18.)

A MIXTURE of potassium fluoride, silica, and carbon is heated in a rotary furnace and treated with gaseous hydrogen chloride. The mass is lixiviated and the solution evaporated. The silicon tetrafluoride evolved during the reaction passes into a chamber containing felspar heated to 500°—600° C., a stream of water vapour being introduced into the chamber. The mixture of potassium fluoride, silica, and aluminium silicate thus produced serves as the starting point for the process. (See also Eng. Pats. 124,554 and 133,474; this J., 1919, 323A, 901A.) —W. J. W.

Potassium sulphate; Manufacture of —. E. E. and P. C. Dutt, Jubbulpore, India. Eng. Pat. 135,545, 18.10.18. (Appl. 17,079/18.)

A MIXTURE of potassium fluoride and clay or silica is heated in a rotary furnace into which sulphur dioxide is introduced. The product is lixiviated and the solution evaporated to dryness. The silicon tetrafluoride evolved in the furnace passes into a chamber containing felspar heated to 500°—600° C., into which a stream of water vapour is also passed. The mixture of potassium fluoride, aluminium silicate, and silica thus produced serves as the starting-point for the process. (See also Eng. Pat. 124,554; this J., 1919, 323A.)—W. J. W.

Ammonium sulphate; Washing —. F. E. Dodge, Flushing, N.Y., Assignor to The Barrett Co. U.S. Pat. 1,321,993, 18.11.19. Appl., 19.6.19.

THE surplus liquid is removed from the crystals by whirling in a perforated centrifugal basket. By means of a three-way valve, liquid can be delivered from a storage tank to a secondary tank, and thence to the centrifugal basket, so that each batch of crystals may be washed with an equal pre-determined quantity of saturated ammonium sulphate solution. A uniform product is thus obtained. —D. F. T.

Greensand; Utilisation of —. E. Hart, Easton, Pa. U.S. Pat. 1,322,900, 25.11.19. Appl., 8.1.17.

THE glauconite fraction of greensand is separated and treated with a strong mineral acid.

—W. E. F. P.

Greensand, marl, and glauconite; Treatment of — [for extraction of potassium compounds]. E. Hart, Easton, Pa. U.S. Pat. 1,323,228, 25.11.19. Appl., 5.6.18.

THE material is treated to produce a solution containing the chlorides of all the metals present except iron. Calcium and aluminium are then precipitated and removed from the solution separately, and the filtrate is evaporated to concentrate the potassium compounds.—W. E. F. P.

Potassium and aluminium compounds; Recovery of — [from greensand]. M. Hauber, jun., West Haverstraw, N.Y. U.S. Pat. 1,323,764, 2.12.19. Appl., 15.7.19.

AN intimate mixture of greensand and ferrous sulphate is heated to convert the greater part of the aluminium and potassium present into sulphates.

—W. E. F. P.

Potassium-bearing silicates; Method of treating —. W. Glaeser, Brooklyn, Assignor to Potash Extraction Corporation, New York. U.S. Pat. 1,323,464, 2.12.19. Appl., 8.3.15.

THE silicate is heated to low redness and suddenly cooled, then powdered and mixed with powdered pyrites. The mixture is burnt in the presence of air and steam at a temperature above 900° C.

—W. E. F. P.

Hydrogen peroxide; Process of making —. D. Levin and L. A. Molin, Buffalo, N.Y., Assignors to Commercial Electrolytic Corporation, New York. U.S. Pat. 1,323,075, 25.11.19. Appl., 5.4.16. Renewed 2.5.19.

HYDROGEN peroxide is obtained from solutions of persulphates by distilling them over heated metallic surfaces resistant to sulphuric acid, a rapid rate of flow of the solution being maintained.—W. J. W.

Manganese dioxide; Purifying —. J. S. Gravely, Assignor to Winchester Repeating Arms Co., New Haven, Conn. U.S. Pat. 1,323,690, 2.12.19. Appl., 14.6.19.

MANGANESE dioxide containing lower oxides is purified by treatment with a solution of a peroxide which removes the water-soluble impurities.

—W. J. W.

Sulphides; Process of oxidation of —. G. N. Libby, Berkeley, Cal. U.S. Pat. 1,323,879, 2.2.19. Appl., 3.2.16.

INSOLUBLE sulphides are oxidised by the electrolysis of alkaline solutions in which they serve as anodes.

—W. J. W.

Sulphur; Method for the preparation of oxygen compounds of — from natural sulphates, especially calcium sulphate. Badische Anilin und Soda Fabrik, Ludwigshafen. Ger. Pat. 298,491, 28.11.16.

NATURAL sulphates are first converted into ammonium sulphate, which is then mixed with anhydrous sodium sulphate and the mixture subjected first to a moderate and finally to a dull red heat. At 400° C. ammonia is driven off and sodium pyrosulphate is formed. As the temperature rises the latter compound is decomposed into sodium sulphate and sulphur trioxide.—T. St.

Chlorine or sulphuryl chloride and sulphates; Method of preparation of —. F. Bergius, Essen. Ger. Pat. 299,031, 30.11.13.

SULPHUR dioxide and air or oxygen are caused to come in contact with a chloride, which must be in a finely divided state, on the counter-current principle, the temperature of the reaction being con-

trolled by the velocity of the gaseous mixture. The reaction is exothermic and if the gas current is properly adjusted, no external heating is required to complete the reaction. The temperature must be maintained between 500° C. and the melting-point of the chloride-sulphate mixture, the upper limit in the earlier stages being 623° C., the melting-point of the eutectic. An excess of sulphur dioxide leads to the formation of sulphuryl chloride.—T. St.

Sulphur dioxide; Purification of the gases containing — produced by calcining alkali bisulphates. Akt.-Ges. Dynamit Nobel, Vienna. Ger. Pat. 299,035, 19.9.16. Int. Conv., 13.9.16.

SULPHUR dioxide of a high degree of purity may be produced by scrubbing the gases generated in the calcination of sodium bisulphate with a saturated solution of sodium bisulphate. The solution, which gradually decreases in strength owing to absorption of water from the gases, is again brought to saturation by the addition of the solid bisulphate.

—L. A. C.

Nitric oxide; Manufacture of — from ammonia and air. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 299,643, 12.1.17.

IN the manufacture of nitric oxide the addition of 2–6 vols. of water vapour to a mixture of 8 vols. of ammonia and 92 vols. of air increases both the yield of nitric oxide and the output of the apparatus.

—L. A. C.

Aluminium silicates; Treatment of naturally occurring —. W. Borchers, Aachen. Ger. Pat. 300,092, 10.2.16.

CLAY and similar substances are mixed with reducing substances, and a quantity of sulphates of alkaline-earths, preferably of magnesium and calcium, sufficient to produce neutral silicates, and the mixture is heated to 900°–1300° C. with admission of steam if necessary. The sulphate sulphur is thus almost entirely driven off as sulphur dioxide, and an alkaline-earth silicate is formed. The alumina can be removed from the mass as sodium aluminate either by roasting with sodium carbonate or by heating with an aqueous solution of sodium hydroxide under pressure. As reducing material may be used sawdust, spent tan and dye-woods, tar and petroleum residues, water-gas, etc.—T. St.

Sodium alum; Production of crude — from clay or kaolin and sodium bisulphate. R. Linkmeyer, Barby. Ger. Pat. 301,611, 7.12.16.

CRUDE sodium alum is produced by treating clay or the like with sodium bisulphate containing approximately 1 mol. of water to 1 mol. of sodium bisulphate; under these conditions the greater part of the aluminium present in the clay combines with the sodium bisulphate, and when the reaction is complete a dry product is obtained which may be readily removed from the vessel.—L. A. C.

Sulphur compounds in gases; Process for precipitating —. Apparate-Vertriebs-Ges. m.b.H., Berlin-Wilmersdorf. Ger. Pat. 309,159, 26.8.16.

SULPHUR dioxide or hydrogen sulphide is introduced, according to whether the gas contains the one or the other of these constituents, and the reaction takes place in the presence of a liquid catalyst in an apparatus resembling a disintegrator, in which the liquid catalyst is atomised into particles of colloid-chemical dimensions. In contact with the impalpable particles of the liquid mist the reaction between hydrogen sulphide and sulphur dioxide takes place so rapidly that a gas containing only small quantities of these impurities is practically completely de-sulphurised. Suitable catalysts are oxides, hydroxides, sulphides, and salts.

—J. F. B.

Phosphates; Production of soluble — from crude phosphates. Chem. Fabr. Budenheim L. Utz m.b.H., Mainz. Ger. Pat. 313,964, 13.2.17.

CRUDE phosphates are treated with an acid, and the requisite amount of ammonia or an alkali base or carbonate is added to the product without previous filtration. The mass is then filtered and heated for the production of soluble phosphates. The preparation of primary ammonium phosphate is described as an example.—L. A. C.

Hydrogen; Method of manufacturing —. Badische Anilin und Soda Fabrik, Ludwigshafen. Ger. Pat. 300,032, 8.4.14. Addition to Ger. Pat. 279,582.

IN the manufacture of hydrogen from carbon monoxide and steam in the presence of a catalyst (Fr. Pat. 459,918 of 1913; this J., 1914, 24), where the latter consists of such forms of metals of the iron group (particularly iron, nickel, cobalt), or their oxides, as are only slightly active, hydroxides or salts of the metal in question are added to increase the activity of the catalyst. For example, iron oxide, which in its preparation was subjected to a high temperature, is formed into a contact mass with damp iron hydroxide; or fine-mesh iron wire gauze, conveniently in the form of a roll, is once or more times acted upon by a concentrated solution of iron nitrate, and then subjected to a moderate heat until the nitrate is completely decomposed. In all cases such contact masses show a considerably higher activity at, say, 500° C., than the original materials.—T. St.

Hydrogen; Regulation of water supply in apparatus for producing and compressing —. F. Lang, Frankenthal. Ger. Pat. 314,260, 24.9.16.

THE air-free cooling water from the compressors used in apparatus for compressing hydrogen is employed for cooling and scrubbing fresh supplies of the gas. Contamination of the hydrogen with the gases present in fresh water is thereby avoided and consumption of water is reduced.—L. A. C.

Nitric acid; Process for concentrating — and apparatus for use in connection therewith. E. C. R. Marks, London. From E. I. du Pont de Nemours and Co., Wilmington, Del., U.S.A. Eng. Pat. 135,535, 6.9.18. (Appl. 14,522/18.)

SEE U.S. Pat. 1,292,948 of 1919; this J., 1919, 285 A.

Sulphuric acid; Method for the concentration of —. A. Dryen, Assignor to Soc. Anon. Fabr. de Soie Artificielle de Tubize, Tubize, Belgium. U.S. Pat. 1,323,847, 2.12.19. Appl., 25.6.15.

SEE Eng. Pat. 10,386 of 1915; this J., 1916, 537.

Potassium; Recovery of — in the form of nitrate from the waste gases of cement kilns and the like. H. Fairbrother, London. From Chemical Construction Co., Los Angeles, Cal., U.S.A. Eng. Pat. 135,713, 20.2.19. (Appl. 4255/19.)

SEE U.S. Pat. 1,296,460 of 1919; this J., 1919, 362 A.

Potassium compounds; Process of recovering —. H. Fairbrother, London. From Chemical Construction Co., Los Angeles, Cal., U.S.A. Eng. Pat. 135,720, 24.2.19. (Appl. 4563/19.)

SEE U.S. Pat. 1,296,463 of 1919; this J., 1919, 362 A.

Ammonium sulphate; Method and apparatus for producing —. H. A. Carpenter, Sewickley, Assignor to Ritter-Conley Manufacturing Co., Pittsburgh, Pa. U.S. Pats. 1,322,757 and 1,322,758, 25.11.19. Appl., 15.2.16 and 18.7.18.

SEE Eng. Pat. 104,155 of 1916; this J., 1917, 548.

Strontium peroxide; Process for manufacture of —. J. B. Pierce, jun., Charleston, W. Va. U.S. Pat. 1,325,043, 16.12.19. Appl., 3.6.18

SEE Eng. Pat. 130,840 of 1918; this J., 1919, 719 A.

VIII.—GLASS; CERAMICS.

Egyptian bricks. G. R. Thompson. Analyst, 1919, 44, 403—405.

BRICKS from the Land of Goshen of undoubted Jewish origin and probably manufactured between 1580 and 1220 B.C., contained no trace of vegetable matter, especially of the nature of straw or wood fibre. The chemical composition of the bricks agreed closely with that of dried Nile mud. The author is of the opinion that straw or stubble was not an integral part of the bricks, and that it was used simply as a non-adherent material to prevent the bricks sticking to the ground during drying or to the workers' hands during moulding. The lumps of mud or the sides of the mould would be covered with chopped straw for this purpose. (See also this J., 1919, 439 B.)—W. P. S.

Anti-dimming compositions. Carleton. See XIXu.

Anti-dimming preparations. Holmes and others. See XIXu.

PATENTS.

Glass-melting furnaces; Gas-fired —. S. G. Curd, Queenborough, Kent. Eng. Pat. 135,636, 5.5.19. (Appl. 20,306/18.)

Is a regenerative gas-heated furnace for melting glass the producer gas is enriched prior to combustion by bringing it into contact with a mixture of iron and carbon, or superheated steam may be so treated and then mixed with the gas. A reservoir may be provided adjacent to the melting furnace, separated from it by a division wall having two cylindrical holes near its base which permit the glass to flow to the reservoir. A honeycombed partition may be mounted upon the division wall to act as a radiator of heat, and a second radiator may take the form of a longitudinal partition in the tank. The upper part of this partition may be honeycombed to permit a partial cross flow of the hot gases. The bottom of the tank and reservoir may be of curved cross-section and the roof of the tank may contain a niche-shaped head in which is the charging hole.—A. B. S.

[*China*] *clay and the like; Mining or quarrying* —. The Osmosis Co., Ltd., and J. S. Highfield, London. Eng. Pat. 135,277, 19.11.18. (Appl. 18,919/18.)

A SMALL quantity (0.05—0.20 %) of an alkaline electrolyte, such as caustic soda or sodium silicate or carbonate, is added to the water used for mining the clay or in the settling pit. The amount of clay which can be retained in suspension is thereby increased from about 5 to 25—50 %, and the amount of liquid to be pumped out of the pit is correspondingly reduced.—A. B. S.

Glass; Machinery for the manufacture of sheet —. A. L. Forster, West Smethwick. Eng. Pat. 135,697, 28.1.19. (Appl. 2017/19.)

Glass cane and glass tubing; Apparatus for drawing —. C. H. Quackenbush and J. C. Smedley, Cleveland, Ohio, Assignors to General Electric Co. U.S. Pat. 1,325,265, 16.12.19. Appl., 29.4.16. SEE Eng. Pat. 105,285 of 1916; this J., 1917, 551.

Clay; Treatment of —. W. Feldenheimer, London. U.S. Pat. 1,324,958, 16.12.19. Appl., 27.11.18. SEE Eng. Pat. 121,191 of 1917; this J., 1919, 41 A.

IX.—BUILDING MATERIALS.

PATENTS.

Mortar, concrete, and like material; Mixing of —. C. Candlot, Paris. Eng. Pat. 128,536, 15.11.18. (Appl. 18,778/18.) Int. Conv., 17.6.18.

THE raw materials for concrete, mortar, and the like are discharged in suitable proportions from separate hoppers, through a common pipe, into a hydrating apparatus and thence into a rotating cylinder, wherein they are further mixed without the addition of any more water.—A. B. S.

Concrete aggregates and materials of a similar nature; Apparatus for mixing together various materials for the dry mixing of —. T. Lea, Wolverhampton. Eng. Pat. 135,511, 16.4.19. (Appl. 16,857/18.)

A MIXING apparatus for dry concrete aggregates and the like consists essentially of two cones or pyramids, one above the other, the higher one, which may be rotated mechanically, having its apex projecting upwards under a feed outlet and its base within the second or inverted hollow cone or pyramid. The materials to be mixed fall on the upper cone or pyramid and pass down its surface, then through the lower cone or pyramid, and through an outlet in the bottom of the latter. —A. B. S.

Portland cement reinforced with organic fibres; Manufacture of plates of —. N. V. Hollandseho Asbest-Cement Fabriek, Schiedam, Holland. Eng. Pat. 130,312, 12.4.19. (Appl. 9393/19.) Int. Conv., 20.7.18.

FIREPROOF and waterproof plates or blocks which can be sawn, bored, nailed, cut, and planed are made of Portland cement reinforced with vegetable fibres, such as wood cellulose, or straw cellulose, which have previously been impregnated successively with a solution or suspension of a fluosilicate and with an alkali silicate in a milling engine or autoclave and then dried.—A. B. S.

Portland cement; Apparatus for manufacture of —. *Utilisation of low-grade carboniferous material.* R. W. Lesley, Haverford, Pa. U.S. Pats. (A) 1,323,293 and (B) 1,323,294, 2.12.19. Appl., 3.9.18 and 21.1.19.

(A) A ROTARY kiln is connected to a retort heated by the waste gases from the kiln. Oil shale is distilled in the retort and the combustible gases are used as fuel for the kiln. The residue from the retort is then conveyed to the kiln and burned to form Portland cement. (B) The heat escaping from a rotary kiln in which Portland cement is burned is used to heat a retort containing low-grade carboniferous material; the gas from the latter is used to heat the kiln.—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; Future development in the manufacture of puddled — J. E. Fletcher. Staffs. Iron and Steel Inst., 22.11.19. Engineering, 1919, 108, 804—806, 836—840.

HALL's process (1820), by promoting intimate contact of molten pig metal and liquid iron oxides, has been shown to be the basis of all open-hearth refining operations in the manufacture of steel and iron, and is not likely to be superseded. The small single-hearth furnace, operated by hand, remains the best means of producing a regular product, though the ordinary puddling furnace is wasteful and the labour and shingling costs are high. The coal consumption per ton of metal produced is twenty times as much in a puddling furnace as in the large open-hearth steel furnace, and this indicates the thermal advantage to be gained by increasing the size of the furnace. Possible improvements in the fire-grates are suggested by employing tubular grate-bars, perforated for air ejection, on which cast-iron discs may be rotated to remove clinker and to disturb the fire. The use of a basic brick capable of withstanding splashes of iron oxide would reduce the erosion losses. The application of gas firing to puddling furnaces has been suggested, and in a design due to Chantaine the furnace is provided with a double arch, the lower one being perforated for the admission of preheated air. Gas passes along the under side of the arch, and combustion is effected in a series of flame jets issuing from the arch and impinging on the metal in the hearth.—C. A. K.

Steels; Phenomena and experimental data in the hardening of — A. Portevin. Chim. et Ind., 1919, 2, 1139—1160.

A GENERAL review of the thermal transformations of carbon steels, together with the variation in mechanical, electrical, and structural characteristics of the metal. The composition of the steel, the quenching temperature, and the rate of cooling are the three principal factors, and the two latter are determined by a consideration of overheating and other defects, and by the mechanical properties desired in the metal after treatment. The necessity of control of all variables is emphasised, and to satisfy the different objectives the proper treatment of any particular steel must be studied independently. (See also this J., 1919, 179 A, 417 A, 418 A.)

—C. A. K.

Steel forgings; Physical defects in — A. Portevin. Publ. de la Rev. de Mét., 1918, 23 pages.

DEFECTS in steel forgings may arise during the casting of the ingot, during the forging or mechanical working stage, or during heat treatment. The different kinds of defects are considered in some detail, and the precautions generally adopted to prevent the occurrence of imperfections in the forged pieces are explained. The methods for detecting the presence of defects at different stages of the process are also indicated. The paper is illustrated with a large number of photographs and diagrams.—E. H. R.

Valve steels in internal-combustion engines; Valve failures and — L. Aitchison. Inst. Automobile Eng., 5.11.19. Engineering, 1919, 108, 799—802, 834—836.

VALVES in petrol engines are subjected in use to a temperature of 100°—600° C. (inlet) and 250°—860° C. (exhaust). The various types of failure are elongation of the stem, distortion of the head, cracks in the valve face, excessive wear of the stem or foot, burning of the head, scaling, and breaking

due to self-hardening. Among other properties steel for valves should possess great strength at relatively high temperatures, and give a satisfactory result under the notched bar test. It should have the capacity for being worked and heat-treated without developing cracks or excessive scale, and its physical properties should be retained after exposure to high temperatures. Experimental data on different classes of steel show that each class of steel, e.g., tungsten-steels, chromium-steels, is different in its properties at high temperatures, but that members of one type are similar. Steels having similar constitution, although belonging to different classes, are alike in mechanical properties. Variation in composition (e.g., in carbon) has a distinct effect on the properties of the steel when hot, though this effect is reduced by a larger proportion of alloying elements. Low-carbon high-chromium (stainless) steel is weaker than a steel with lower chromium and higher carbon content, or than 0.6% tungsten-steel, and nickel or nickel-chromium steels are quite weak at high temperatures compared with other steels. Vanadium has apparently little effect on the properties of tungsten steels when hot. Nickel-chromium steels are unsatisfactory, and high chromium steels (above 7% Cr) are the most resistant to scaling. Tungsten-steels begin to scale rapidly about 850° C. The following steels are recommended:—For inlet valves, 3% nickel steel (C 0.30—0.35, Ni 2.75—3.75, Mn 0.40—0.70%), quenched in oil from 830° C. and tempered at 625° C.; for exhaust valves with a working temperature of 600°—700° C., high chromium steel (C 0.65, Si 0.60, Mn 0.50, Cr 10.0%), hardened in air from 900° C. and tempered at 750° C.; for exhaust valves working above 760° C., tungsten-steel (C 0.65, W 16.00, Cr 3.75%), refined at 950° C., cooled in air, and tempered at 800° C.—C. A. K.

Zinc ores, residues, and ashes; Utilisation of low-grade — Wöbling. Metall u. Erz, 1919, 16, 420—422.

THE materials dealt with are poor calamine deposits, residues from ore washing, ashes and muffle fragments containing zinc. Proposed methods of treatment, including leaching and electrolytic processes, are reviewed, and it is concluded that the extraction of zinc from these low-grade materials is only possible if the cost of treatment can be considerably reduced. In laboratory experiments complete reduction has been obtained by means of charcoal.

—T. H. Bu.

Zinc retorts; Influence of the pressure in — on the output of metal. O. Mühlhæuser. Metall u. Erz, 1919, 16, 363—373.

THE author has previously shown the effect of difference of pressure between the retort and the combustion chamber on the movement of gas through the retort walls (this J., 1919, 725 A). In further tests the output of retorts kept artificially under pressure has been determined and compared with the results of ordinary practice. The permeability of muffles varies considerably. In damaged retorts the loss of metal increases with the pressure in a measure corresponding with the extent of the damage. In undamaged retorts the loss does not generally increase with the pressure. When the retort is not very permeable the metal loss may sometimes be reduced by opening the receiver. If a retort is damaged and the permeability of the muffle correspondingly high the gases of combustion will penetrate the vessel in large quantities in consequence of the excess pressure in the furnace, and correspondingly larger amounts of zinc vapour are expelled from the condenser, as indicated by the intense green colour of the condenser flame. Zinc furnaces should be always kept under the highest possible pressure. In retorts with cracks or

holes the loss of metal generally becomes excessive only if a resistance to the passage of the gases is formed in the throat of the muffle or the interior of the receiver, or if the plug sealing the throat of the receiver becomes too impervious by clogging up with zinc dust.—T. H. Bu.

Pyrophoric [zinc] alloys; Utilisation of German supplies of —. W. Guertler. *Z. Metallkunde*, 1919, 10, 209—213. *Chem.-Zeit.*, 1919, 43, Rep., 260.

The alloy consists of zinc with a few per cent. of copper and aluminium, and is available in large quantities. Different methods of separation are discussed. The alloy may be heated until it separates into solid and fluid components, pure zinc being isolated. Electrolytic refining gives pure copper and zinc, but has not yet been technically perfected. The distillation of zinc is at present too costly. The removal of aluminium and copper is possible by chemical methods; also by melting the alloy with zinc oxide to oxidise the aluminium and removing the copper by another method. The alloy is too brittle for most purposes. It might be useful for galvanising.—T. H. Bu.

Aluminium-copper-zinc; The ternary system — with special reference to the zinc corner of the equilibrium diagram. V. Jares. *Int. Zeits. Metallg.*, 1919, 10, 1—11. *Chem. Zentr.*, 1919, 90, 111., 512.

THE copper corner of this ternary system has already been worked out satisfactorily by Carpenter and Edwards (this J., 1912, 778), and the present work is confined to the zinc corner of the diagram. From the results of the thermal investigation of the alloys a space diagram has been constructed. For the examination of the mechanical properties of the alloys they were prepared from a commercial zinc containing 1% Pb. In the zinc-aluminium system the hardness of the slowly cooled samples increases very rapidly with the aluminium content up to 70 (Brinell) at 10% Al, remains constant up to about 20% Al, and then increases very slowly. In the zinc-copper system it reaches a maximum at about 5% Cu, then sinks to a minimum at 12—14% Cu, and again rises very quickly. The minimum of the Zn-Cu alloys also appears in the ternary alloys when these are cooled slowly, but with quick cooling it does not occur and the hardness increases more regularly. The tensile strength of the Zn-Al alloys tested was lower than that given by Portevin (this J., 1911, 1216) and Ewen and Turner (this J., 1910, 1163), probably owing to the lead content. The Cu-Zn alloys show a maximum tensile strength at about 10% Cu. The strength of the Zn-Al alloys increases fairly rapidly with increase of copper up to about 8—10% Cu and then falls. The fractured surface of zinc becomes finer with increase of Al, retaining its ray structure, but with addition of copper it quickly becomes fine-grained. An alloy with 90% Zn, 6% Cu, and 4% Al has a very high crushing strength, twice that of tin bearing metal. Al-CuZn alloys ("white brass") as hard and strong as brass or bronze can readily be obtained, but owing to their brittleness they are not efficient substitutes for these. For technical use white brass should not contain less than 4% nor more than 10% Cu. The aluminium content should not exceed 5%, and should be diminished as the copper content increases. The addition of certain metals (Pb, Fe, Mn, Ni) may slightly increase the hardness and strength, but the tenacity and elasticity are not improved. The Al-Cu-Zn alloys rich in zinc can be used as substitutes for bearing metals, although they are less soft and plastic. White brass is not suitable for use with steam, as it oxidises too readily, withstands only moderate pressures and is rapidly corroded

by many salt solutions, natural waters, etc. It can very well be used for mechanical and physical instruments.—E. H. R.

Detinning industry. L. Hackspill. *Chim. et Ind.*, 1919, 2, 1161—1167.

A REVIEW of the methods employed for the recovery of tin from tinned iron. Complete removal of tin should be effected so as to enable the iron to be used again, and this can never be accomplished by the process of brushing or centrifuging the molten tin coating. An interesting though not a commercial process of physical separation consists in cooling the tinned metal in liquid air, thus converting the tin into an allotropic modification which is easily detachable. In chemical methods for detinning iron an agent is used which will attack tin, and the resulting solution is treated for the recovery of the small quantities of iron compounds also formed. Thus, hydrochloric acid is used with formation of stannous chloride and small quantities of lead chloride and ferrous chloride. After precipitating lead by means of sulphuric acid metallic tin is obtained by treating the solution with zinc or aluminium or magnesium alloys. An ingenious method of reducing the tin salt by the residual iron, due to Schultze (*Eng. Pat.* 3669 of 1887, this J., 1888, 388; see also this J., 1890, 550), is very slow, and has not been employed on the large scale. Sodium hydroxide in presence of an oxidising agent, e.g., lead oxide or sodium nitrate, will dissolve tin with the formation of sodium stannate, without attacking the iron. The process applied to 75% of the metal treated depends on the reaction between chlorine and tin. This reaction is extremely rapid, and the principal difficulty lies in dissipating the heat evolved. In the recovery of tin by electrolytic means the tinned metal is employed as anode, with an insoluble cathode, in an electrolyte consisting of a solution of sodium hydroxide or sodium sulphide.—C. A. K.

Zirconium ore; Analysis of Brazilian —. A. R. Powell and W. R. Schoeller. *Analyst*, 1919, 44, 397—400.

FIVE grms. of the sample, ground to pass a 90-mesh sieve, is treated with a magnet to remove particles of iron introduced in the grinding and then dried at 100° C. for 1 hr.; the loss on ignition is determined on 1 gm. of the dry ore. A further 5 grms. of the sample is then ground under water in an agate mortar and the slime decanted from time to time into a porcelain basin; when but little sandy material is left, iron is removed with a magnet, the grinding finished, and the slime evaporated to dryness. About 0.5 gm. of the dry slime is ignited in a platinum basin to constant weight, then fused with 5 grms. of sodium carbonate for 1 hr., the melt dissolved in boiling water, and any insoluble residue collected on a filter. This insoluble matter is ignited, fused with potassium bisulphate, the melt treated with 1% sulphuric acid, and the still insoluble portion collected on a filter (filtrate A). The solution from the sodium carbonate fusion is meanwhile evaporated with the addition of hydrochloric acid and the silica separated and collected (filtrate B). The silica precipitate, together with the insoluble residue from the bisulphate fusion, is ignited, weighed, evaporated with hydrofluoric and sulphuric acids, the residue weighed, fused with bisulphate, and dissolved in 1% sulphuric acid. This solution is added to the two filtrates (A and B), the solution nearly neutralised with sodium carbonate, a slight excess of sulphuric acid is added together with a little pulped filter-paper, and the mixture is saturated with hydrogen sulphide. After 18 hrs. the platinum sulphide is collected and washed with 1% sodium chloride solution. The filtrate is nearly neutralised with sodium carbonate and boiled while a current of carbon dioxide is

passed through it to expel all hydrogen sulphide. The solution is then boiled for 1 hr. with the addition of 10 grms. of sodium thiosulphate, the precipitate collected, washed with boiling water, ignited and weighed; it consists of ZrO_2 , TiO_2 , and Al_2O_3 . To determine these constituents separately the ignited precipitate is fused for 1 hr. with 30 times its weight of sodium carbonate, the melt boiled with water and 2 grms. of sodium hydroxide, the solution filtered, and the insoluble portion washed with 2% sodium carbonate solution. The alkaline filtrate is poured into an excess of dilute nitric acid, the solution boiled to expel carbon dioxide, and the aluminium then precipitated as hydroxide by ammonia. The precipitate is ignited and weighed, then fused with bisulphate, dissolved in sulphuric acid, and tested with hydrogen peroxide; it sometimes contains a trace of titanium. The insoluble portion from the sodium carbonate fusion is ignited, fused with 5 grms. of bisulphate, the melt extracted with 1% sulphuric acid, the solution diluted to 200 c.c., and 20 c.c. is treated with 2 drops of hydrogen peroxide. The colour obtained is compared with that produced by a known amount of titanium under the same conditions. The amount of zirconia is found by difference. Iron, manganese, calcium, and magnesium are determined in the filtrate from the thiosulphate precipitate after the solution has been boiled with nitric acid and filtered to remove sulphur.

PATENTS.

Iron or steel articles; Hardening or like treatment of —. E. H. Jones, London. Eng. Pat. 134,864, 12.8.18. (Appl. 13,054/18.)

IRON or mild steel articles, turned to finished size, are plated with a metal having a fusion point near to or higher than that of iron, e.g., nickel, cobalt, vanadium, chromium. The plated articles, protected from oxidation, are then heated to and maintained at 1000° – 1200° C. for 8–4 hours until the metal coating penetrates the iron. It is necessary to protect a chromium or vanadium plating by a further deposit of a comparatively non-fugitive metal, e.g., nickel or iron. In many cases the articles may with advantage be subjected to a case-hardening process during the heating period.

—C. A. K.

Steel; Manufacture of —. *Casting iron or steel or their alloys.* F. E. Falvet, Paris. Eng. Pats. (A) 134,915, and (B) 134,916, 12.11.18. (Appls. 18,518 and 18,519/18.)

(A) The necessary proportions of iron, tungsten, vanadium, or other metals required for high-speed steels are heated together to about 1200° C., and 0.2–5% of ferro- or ferri-cyanide of potassium or sodium is added, together with slag-forming material. The temperature is then raised to 1800° C., and the metal cast, with or without a supplementary addition of ferro- or ferri-cyanide. (B) The addition of ferro- or ferri-cyanide as specified under (A) is applied to the production of castings of steel, iron, or their alloys.—C. A. K.

Pig-iron; Process of producing high-phosphorus — [and nitrogen-potassium-carbon compounds from greensand]. T. C. Meadows, New York. U.S. Pat. 1,322,038, 18.11.19. Appl., 4.5.18.

A MIXTURE of greensand, phosphate rock, and fuel is smelted in a blast furnace, molten high phosphorus pig-iron being tapped off, and nitrogen-

potassium-carbon compounds recovered from the furnaces gases, which are drawn off immediately, above the reaction zone.—C. A. K.

Steel; Product for carbonising —. T. R. Ferguson and E. L. Larson, Chicago, Ill., Assignors to A. O. Blach Co. U.S. Pat. 1,322,298, 18.11.19. Appl., 1.4.18.

A CASE-HARDENING compound for steel consists of charred pecan shells, free from moisture or oils.

—C. A. K.

Foundry and pig-iron; Method and shaft furnace for the synthetic production of high-grade —. Rombacher Hüttenwerk, J. I. Bronn, and W. Schemmann, Rombach. Ger. Pat. 299,662, 17.4.15.

MOLTEN refined iron of low carbon content is allowed to descend through a shaft furnace filled with coke which is maintained at a high temperature throughout by means either of a blast introduced through tuyeres or electrodes, or both, at different levels, whereby the iron is caused to take up carbon up to 3%, or more, according to the height of the coke column. By mixing small pieces of ferrosilicon or ferromanganese with the coke silicon or manganese may also be added to the iron.

—T. St.

Lead and tin; Recovery of — from their solutions. W. G. Rumbold, London. Eng. Pat. 135,052, 28.1.19. (Appl. 2132/19.)

A SOLUTION of lead (or tin) chloride in ferrous chloride solution, obtained by the known method of treating the metals with a solution of ferric chloride, is mixed with an excess of ferrous chloride in concentrated solution and treated with clean scrap iron at 60° – 80° C. The lead or tin is deposited on the iron, and the solution may be regenerated for the treatment of a further quantity of metal. A similar reaction for tin takes place from its sulphate solution in the presence of a concentrated solution of ferrous sulphate.—C. A. K.

Alloys rich in lead; Process of making —. J. P. Arend, Dommeldange, Luxembourg. Eng. Pat. 135,056, 31.1.19. (Appl. 2496/19.)

ALLOYS of copper, tin, zinc, and lead consist of a skeleton of the alloy of the higher melting metals, in which the lead is carried. Such alloys are usually not uniform in structure, particularly if such a metal as zinc is present in sufficient quantity to prevent the solidification of the skeleton alloy until considerable separation of the lead has occurred. By the present method the alloy mixture is melted in an induction furnace. The unalloyed lead particles offer a much higher electrical resistance than the particles of copper-tin or copper-zinc, and thus acquire a higher temperature and more rapid motion. The lead thus becomes disseminated and "emulsified," and during the solidification period the small particles readily adhere to the other metals and produce an alloy of more uniform structure.—C. A. K.

Electrolytic copper; Process for manufacturing pure — from cement copper. A. G. Sundberg and T. E. Thomasson, Helsingborg, Sweden. Eng. Pat. 135,125, 6.5.19. (Appl. 11,312/19.)

CEMENT copper is roasted, or oxidised by other means, and is dissolved in a quantity of acid electrolyte, withdrawn during the normal process of electrolysis with insoluble anodes, the solution then being returned to the electrolysis tank. The process is made continuous by withdrawing acid solution equivalent to the metallic copper deposited, an equal amount of copper then being dissolved by the acid solution. Impurities in the cement copper are prevented from passing into solution by the

excess of copper oxide present when the neutral stage of the extraction is reached.—C. A. K.

Crucible furnaces. W. A. Shilton and R. A. Munden, Coventry. Eng. Pat. 135,241, 17.10.18. (Appl. 16,937/18.)

THE crucible heating chamber is made in the form of a bell open at the bottom, and adapted to stand on the furnace base and enclose the crucible. It is heated either by gas or by hydrocarbons, the burners passing through lateral openings. The bell can be raised or lowered, and in the top is a central outlet for waste gases with inclined or rounded shoulders so as to deflect the flames and heat into the crucible.—J. W. D.

Crucible furnaces for melting aluminium and the like. C. F. Price, Birmingham. Eng. Pat. 135,247, 21.10.18. (Appl. 17,151/18.)

THE crucible, which can be tapped either at the top or bottom, fits into the top plate of the furnace, and is retained in an upright position by firebrick projections from the back and sides of the furnace lining, the bottom resting on an arch which spans the fire grate below. In the top plate are openings for charging fuel, and in the sides of the furnace a series of openings with removable blocks for admitting and regulating a supply of air. Below the outlet flue a baffle is provided between the crucible and the casing in order to deflect the heat round the crucible.—J. W. D.

Crucible and like furnaces. J. H. Ratson, Gateshead-on-Tyne. Eng. Pat. 135,447, 10.7.19. (Appl. 17,349/19.)

AT the bottom of the furnace a metal base-plate is arranged having bangers or depending brackets which support the fire-bars and are connected to or support perforated side plates through which air can enter the fire in addition to that entering from beneath the fire-bars. The firebrick casing or lining of the furnace is supported by this base-plate.—J. W. D.

Retort furnace for the recovery of zinc by the reduction of zinc oxide. H. Bursitzky, Laura-hütte. Ger. Pat. 314,131, 23.2.15.

ALL the retorts are connected with a common condensing chamber in the form of a shaft which extends downwards sufficiently for the temperature at the bottom to remain below the vaporising point of zinc, and is provided with an outlet for carbon monoxide at the top. The retorts are each provided with two projecting openings, one above, constituting a hopper for the continuous charging of the retort, and one in front for the periodical removal of ashes. The masonry surrounding the condensing chamber contains a sand-seal to prevent the penetration of air.—T. St.

Martin furnace; Operation of a tilting — using a mixture of low-grade and high-grade gas. Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G., Abteil. Dortmunder Union, and A. Klinkenberg, Dortmund. Ger. Pat. 314,235, 4.7.18.

THE charge in a Martin furnace is first melted by the mixed gas under normal oxidising conditions; the supply of low-grade gas is then shut off, and by means of the high-grade gas the charge is heated to a higher temperature in an atmosphere as low in oxygen as possible, whereby a slug of high basicity is formed which takes up the phosphorus and sulphur from the charge. The slag is then removed by tilting the furnace. The carbon content of the charge is not lowered by the treatment, and chromium, nickel, tungsten and the like

are not taken up by the slag. By the addition of more lime and subsequent removal of the fresh slag the last traces of phosphorus and sulphur may be removed.—L. A. C.

Roasting furnace; Gas-fired —. Donnersmarckhütte, Oberschlesische Eisen- und Kohlenwerke A.-G., Hindenburg. Ger. Pat. 314,263, 17.7.18. Addition to Ger. Pat. 310,283 (this J., 1919, 641 A).

IN roasting ores which require heating to 300° C. or more to drive off water of constitution there is a danger, if ore dust has been allowed to cake on the plates, that when this temperature is reached the water vapour may escape with explosive violence, and thus interfere with the smooth working of the furnace. To prevent the formation of such caked dust on the plates in the high-temperature zone of the furnace these plates are made with perforations through which loose dust drops. This dust is received on parallel plates situated below, and is returned to the main stream of ore.—T. St.

Minerals; Flotation of —. C. L. Perkins, Pittsburgh, Pa., Assignor to Metals Recovery Co., New York. U.S. Pat. 1,322,816, 25.11.19. Appl., 2.7.19.

A SMALL amount of toluidine is added to the mineral pulp, and the mixture is subjected to a flotation operation.—S. S. A.

Casting molten metal. A. R. Earnshaw, Riverton, N.J. U.S. Pat. 1,323,583, 2.12.19. Appl., 12.6.18.

MOLTEN metal on the way from the ladle or other container to the mould is broken up into relatively small globules and subjected to a gaseous cooling medium. Both actions can be effected by means of a suitable jet of gas under pressure.—B. M. V.

Alloys; Method of separating the constituents of — by "blowing" the molten metal. J. E. Knudsen, Mühlbach. Ger. Pat. 299,631, 17.7.15. Int. Conv., 11.6.15.

COPPER alloys are melted with scrap iron and air is blown through the molten metal, the oxidation of the iron furnishing the necessary heat to keep the copper molten; whilst zinc distils and is recovered as oxide. The action is interrupted for the addition of quartz sand, which serves as a flux for the iron oxide formed. About 85% of the copper in brass is thus recoverable with a purity of 99%, and about 71% of the zinc. Bronze requires more iron than does brass, and the tin passes into the slag. Nickel bronze and German silver yield a copper-nickel alloy, and any precious metals present are concentrated in the copper or copper-nickel.—T. St.

Slags rich in iron; Producing — from lead and copper smelting. W. Buddens, Berlin. Ger. Pat. 302,537, 20.3.17.

SLAGS from lead and copper smelting are unsuitable for the blast furnace on account of the presence of zinc (10%), lead, and copper. Complete separation of the metallic impurities is effected if a small part of the iron in the slag is reduced to metallic iron, which quickly takes up the copper, the lead and zinc being driven off. The slag, with or without addition of material rich in iron, is mixed with fuel in a shaft furnace having two widely distant rows of tuyères and smelted with hot blast, so that at the level of the upper row the slag is quickly melted, and at the level of the lower row the iron

is partly reduced. The mixture of ferrous oxide slag and iron containing some copper flows into the fore-hearth or slag pot in which the iron is separated from the slag.—T. H. Bu.

Tungsten; Production of chemically pure — for incandescence bodies in electric lamps. Lohmann und Heckmann Metallfabr. Ges., Neukölln. Ger. Pat. 306,364, 31.1.15.

AMORPHOUS tungsten metal, tungstic anhydride or the like is transformed in a carbon tube resistance furnace into tungsten carbide. This is finely powdered and placed in a carbon mould which is introduced into a high temperature furnace fixed to a rotating wheel. The high temperature and the centrifugal force produce a homogeneous body of tungsten carbide. The latter is mixed with tungsten oxide or other material containing oxygen, and exposed for a long time to a temperature not reaching the melting point of tungsten. By this means the carbon is extracted from the carbide and pure workable tungsten metal free from pores is obtained.—T. H. Bu.

Fine-grained ores; Smelting — in a blast-furnace or the like. O. Baumann, Amberg. Ger. Pat. 312,935, 2.11.17.

THE fine ore is introduced into the furnace, together with finely-divided carbon and flux, by means of the air blast. To prevent premature slagging in the furnace and stoppage of the tuyères the ore is preferably reduced as far as possible before adding to the air blast, so that finely-divided iron generally containing gangue is blown into the blast-furnace. In the blast-furnace the usual charge of ore and coke is fed into the shaft and the fine dusty material is introduced through the tuyères with the blast. A considerable part of the waste gases is withdrawn from the furnace hearth, so that the direction of the blast is principally downwards and the melting zone lies below the tuyères. These gases are used in the ore reduction furnace. To obtain iron low in carbon the molten iron is withdrawn from contact with the coke and collected in a fore-hearth.—T. H. Bu.

Tin; Production of — free from iron, from waste tin-plate and the like. Chem. Fabr. Buckau, Magdeburg, and T. Silbermann, Halle. Ger. Pat. 314,592, 16.1.15.

WASTE tin-plate and the like is treated with an acid, and a stannous compound is precipitated from the solution obtained by the immediate addition of just sufficient alkali or alkaline-earth oxide, hydroxide, or carbonate to give a precipitate free from iron compounds.—L. A. C.

Metal articles; Hardening, or hardening and tempering, of needles, pins, spikes and like —. A. Imbery, Halifax. Eng. Pat. 135,640, 7.12.18. (Appl. 20,385/18.)

XI.—ELECTRO-CHEMISTRY.

Electro-chemical industry [in Germany]; Development of —. H. Goldschmidt. Z. Ver. deutsch. Ing., 1919, 918. Chem.-Zeit., 1919, 43, Rep., 272. (See also this J., 1919, 951 A.)

FERRO-TUNGSTEN is now prepared containing 75—85% W and 0.5—0.8% C. A 50—60% product can be made by a continuous process, but the product of higher tungsten content is too viscous and must be withdrawn from the furnace intermittently. The world-production of tungsten rose from 72 tons in 1892 to 10,600 tons in 1913. In that year Germany imported 5000 tons of tungsten ore, and exported 2200 tons to England. During the war tungsten was recovered from tin slags, 220—230 tons being thus recovered in 1916. The price rose from M. 5.5 per kilo. in 1914 to M. 80 in 1915. Ferro-chromium has been manufactured in large quantities (7000 tons) during the war, but Germany does not control any supplies of chrome ore; 5000 tons of chromium was imported formerly from France, Switzerland, and Scandinavia. Ferro-silicon was imported (20,000 tons) from Switzerland and Scandinavia, but here also war-time developments will render this unnecessary in the future. To make 1000 kilos. of ferrosilicon (75% Si) 10,000 kilowatts is required. Phosphorus, fused quartz, carborundum, and graphite are all produced electrolytically. Artificial graphite is superior in some respects to the natural material, e.g., in electrical conductivity. Of the pre-war German consumption of copper (260,000 tons) the home production amounted to 40,000 tons. In America over 1,000,000 tons was made in 1918, i.e., more than the world's output before the war. There is also general over-production of chlorine, so that the prospects for German export trade are poor. In inorganic chemistry chlorine might replace sulphuric acid. Electrolytic hydrogen and oxygen have been produced in increased quantities, the latter being used with advantage for cutting steel. The prospects of oxygen manufacture are considered very favourable. The cheap water power so necessary for these electro-chemical industries is available in Bavaria.

—H. J. H.

Electrolysis of solutions of iron; Potential necessary for the —. W. A. Noyes. Comptes rend., 1919, 169, 971—973.

THE minimum potential necessary for the electrolysis of a solution of a ferrous salt between electrodes of electrolytic iron is 0.66 volt at 20° C. This value decreases 0.007 volt for 1° C. rise in temperature, attaining a minimum at 110° C. and then rising with further rise in temperature.

—W. G.

PATENTS.

Depolarising agent; Electrolytic higher oxide of manganese — and process of making same. Densified polarising agent and process of making same. C. Ellis, Montclair, N.J., Assignor to National Carbon Co., Inc., Cleveland, Ohio. U.S. Pats. (A) 1,322,000 and (B) 1,322,001, 18.11.19. Appl., 6.12.16.

(A) A SOLUTION of manganous sulphate and another sulphate is electrolysed, whereby a higher oxide of manganese is produced; this is removed without coming into contact with the nascent hydrogen evolved. (B) Finely-divided basic manganous material is roasted to form manganese dioxide, which is mixed with finely-divided graphite and a binding agent. The mixture is subjected to a pressure of several tons per sq. in., then pulverised and re-shaped in moulds at a lower pressure than was previously used.—J. H. J.

Insulating aluminium-covered copper conductors; Methods of —. H. M. and H. D. Abernethy, Cleveland, Ohio, Assignors to H. Fuller, East Cleveland, Ohio. U.S. Pat. 1,323,236, 2.12.19. Appl., 17.4.16.

AN electrical conductor covered with a thin coating of aluminium is electrolysed by a current of low voltage and amperage in an aqueous solution of potassium permanganate and sulphuric acid. The conductor serves as the anode, and the cathode is composed of a porous cup filled with mercury.—L. A. C.

Electric furnace. W. H. Bristol, Waterbury, and M. J. Johnson, Naugatuck, Conn., Assignors to The Bristol Co., Waterbury, Conn. U.S. Pat. 1,323,576, 2.12.19. Appl., 14.1.19.

IN a furnace of the resistance type the resistance material is placed in an opening hollowed out of the top of horizontal electrodes.—B. M. V.

Gases; Method of purifying or separating — by means of high-tension electricity. Siemens-Schuckertwerke G.m.b.H., Siemensstadt. Ger. Pat. 314,171, 27.2.18.

THE gas is made to pass over high-tension electrodes provided with points or edges through a conduit on the sides of which are placed plate-like collecting electrodes. The composition of the gas stream over its cross-section thus alters, the impurities tending to pass towards the walls of the conduit. Separation of the gas into parts containing lesser and greater amounts of impurity is then effected by means of wedge-shaped separating walls placed in the conduit beyond the electrodes.—T. St.

Oxidation of sulphides. U.S. Pat. 1,323,879. See VII.

XII.—FATS; OILS; WAXES.

Tobacco seed oil. K. Preissecker and H. Brezina. Fachl. Mitt. Oesterr. Tabakregie, 1917, No. 4. Chem.-Zeit, 1919, 43, Rep., 288.

EXPERIMENTS on a large scale were made in 1915 on the extraction of Dalmatian tobacco seeds with trichloroethylene. The average yield was 35.4% of oil having the following characters:—Sp. gr. 0.9250 at 15° C.; acid value, 9.5; saponif. value, 196.4; and iodine value, 131.6. The oil-cake contained a relatively high proportion of nitrogen and fat; it would probably be suitable for fodder.—C. A. M.

Cnicus Benedictus oil. A. Ferencz. Arch. Pharm., 1919, 257, 180—190.

THE oil of *Cnicus Benedictus* seeds is odourless and tasteless, that pressed cold being pale yellow and

that pressed hot dark brown; both oils exhibit semi-drying properties. The physical and chemical characters are as follows:—Sp. gr. at 15° C., 0.9262; acid value, 1.2; refractive index, 1.47178; saponification value, 191; iodine value, 141; Hehner value, 95.75; Reichert-Meißl value, 2.53; Polenske value 0.60; unsaponifiable matter, 0.66; iodine value of unsaturated fatty acids, 146. The unsaturated fatty acids consist of about 71% of oleic and 26% of linolic acids, and the saturated fatty acids of about 40% of stearic and 60% of palmitic acids. According to Pater (Természettudományi Közlöny, 1917, 675—676) the seeds contain 24.1—28.3% of fatty oil, 14.83% being obtainable by pressing in the cold.—T. H. P.

Beeswax; Influence of cholesterol esters on the saponification of —. P. Böhrisch. Pharm. Zentralh., 1919, 60, 473—478.

A SAMPLE of East African beeswax examined by the author contained 0.61% of cholesterol esters and a sample of East Indian beeswax 0.22%. Since ordinary (German) beeswax contains 0.6—0.7% of these esters, the difficulty with which the foreign waxes saponify cannot be due to their presence.—W. P. S.

Colloidal electrolytes: Soap solutions as a type. J. W. McBain, M. E. Laing, and A. F. Tittley. Chem. Soc. Trans., 1919, 115, 1279—1300.

THE study of the electrical conductivity and other properties of soap solutions has led one of the authors to define a new class of compounds, colloidal electrolytes, of which soap solutions are a type (McBain, this J., 1918, 219 r). Conductivity and freezing point data are given for a number of sodium and potassium salts of fatty acids, including acetic, octoic, decoic, lauric, oleic, and stearic acids. The striking point about the conductivity curves is that they represent moderately good conductivities even in concentrated solutions. In many cases the conductivity curve, after passing through a minimum, rises on further concentration to a maximum, an effect which is more pronounced at lower than at higher temperatures, and more for potassium than for sodium salts. The soap solutions also show an abnormally high temperature coefficient of conductivity. The osmotic properties of soap solutions were best studied by the freezing point method. From the data obtained for the lowering of the freezing point it was possible to calculate the concentration of crystalloid in the solutions. It was found that, in all but the most dilute solutions, the soap exists almost entirely as colloid. In high dilution and especially at higher temperatures, e.g., 90° C., the soap is almost entirely crystalloid. The octoate shows properties intermediate between those of an acetate and a true soap. The phenomena are well explained by the hypothesis of ionic micelle, according to which the negative ions of the soap are aggregated to form the nucleus of a colloidal particle, termed the ionic micelle, whilst retaining their equivalent electric charges. Thus the ionic micelle exhibits conductivity as well as mobility even greater than the ions contained in it. The micelle probably combines with non-ionised molecules and with water of hydration. The change in hydration with increasing temperature explains the abnormal temperature coefficient of conductivity.—E. H. R.

Soap curd; Degree of hydration of the particles which form the structural basis of — determined in experiments on salting out. J. W. McBain and M. Taylor. Chem. Soc. Trans., 1919, 115, 1300—1308.

WHEN a soap, for instance, sodium palmitate, is salted out by sodium hydroxide, marked apparent negative sorption occurs, since the concentration of alkali in the lye becomes much higher than before.

By analysis of the soap curd and of the lye it is shown that the curd is a mechanical mixture of hydrate (or sorption compound) and enmeshed lye. The degree of hydration in the case of sodium palmitate varies with the concentration of the lye. Thus, when the concentration is 3*N* the sorption compound has the composition $\text{NaP} \cdot 3\text{H}_2\text{O}$, and for 1.5*N* the composition is $\text{NaP} \cdot 6.5\text{H}_2\text{O}$, where *P* represents the palmitic acid radical. Under extremely high pressures the degree of hydration is lowered considerably.—E. H. R.

Althaea root. Von Friedrichs. See XX.

PATENTS.

Oils and fats and the like; Deodorising and purifying —. G. Calvert, Twickenham Park. Eng. Pat. 135,295, 21.11.18. (Appl. 19,126/18.)

OILS, fats, etc., are heated in contact with a finely divided substance or substances and a non-oxidising non-flavouring gas, such as hydrogen, nitrogen, or carbon dioxide, or a non-aqueous vapour, such as petroleum spirit, ethyl acetate, or a mixture of these. The contact material may either be of natural occurrence, e.g. kieselguhr, or it may be prepared artificially, e.g., hydrated aluminium silicate deposited on kieselguhr, and be capable of acting as a carrier for objectionable substances not removed by the gas or vapour, whilst being itself left in a condition suitable for separation from the oil or fat. In one modification of the process the fatty acids or glycerides are sprayed into a chamber, where they are mechanically agitated in contact with the material and in the current of gas. Various forms of apparatus for carrying out the process are described.—C. A. M.

Fuller's earth [for oil refining]; Process for the production of —. J. Kohndorfer, Landshut. Ger. Pat. 305,452, 3.6.14.

FINELY powdered silicate rocks or silicious earths are treated with dilute sulphuric acid at 80°–100° C. The hot mixture is neutralised with ammonia, and the precipitate is separated from the liquid which can be further worked up for ammonium sulphate.—J. H. J.

Oils and fats containing phosphoric acid; Process for the production of —. Chem. Fab. Flörsheim H. Noerdlinger, Flörsheim. Ger. Pat. 313,617, 23.11.17.

PHOSPHORIC anhydride is dissolved in the cold in castor oil or other hydroxy-acid oil and after a short time a tough glassy mass forms, from which by repeated washing and heating with water an oil is obtained soluble in ammonia and soda. The oil derived from castor oil has the following characters: sp. gr. at 15° C. 1.0133, acid value 192.3, saponification value 278.2; P_2O_5 content, 8.81%. The products are soluble in ether and petroleum spirit and insoluble in water and benzene. On heating with hydrochloric acid the phosphoric acid is not completely separated. If the oils are mixed with less than the quantity of alkali required for saponification and heated to the boiling point a gelatinous or solid soap is obtained, neutral in reaction and giving a clear solution in water.—J. H. J.

Pieric acid stains on the skin; Preparation of a reagent for the removal of —. J. Klemenz, Dresden. Ger. Pat. 312,772, 1.6.18.

A SUITABLE detergent, such as water glass, Glauber's salt, or soap, is mixed with bleaching powder.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Illumination from paint. H. A. Gardner. Circ. 76, Paint Manufacturers' Assoc., U.S.A., Nov., 1919. 8 pp.

The light-reflecting power of a number of paints and pigments was determined by applying three coats of the paint under test to pieces of sheet tin about 6 in. square, primed with flat lithopone paint. The reflection factor was determined in an integrating sphere in which a beam of light was thrown on the samples at an angle of 15° to the normal. A freshly surfaced block of magnesium carbonate having a reflection factor of 88 was taken as the standard. Examination of some commercial paints showed that flat paints gave higher reflection values than gloss paints, most probably on account of the higher pigment content. Aluminium enamel gave a reflection factor of 52, as against 76 for flat interior wall paint, a surprising result in view of the generally accepted view as to the high light-reflecting power of the former. Tests on various paints compounded on both a weight and a volume relationship showed conclusively the higher reflecting values obtained by increasing proportions of pigment. Paints of high reflecting power can be made by using a relatively small proportion of highly viscous binding medium thinned down with volatile solvent.—A. de W.

Resins; Determination of the saponification value of dark —. H. Salvaterra. Chem.-Zeit., 1919, 43, 765–766.

FOUR grms. of the resin is boiled for 30 mins. beneath a reflux condenser, with 50 c.c. of *N*/2 alcoholic potassium hydroxide solution, then treated with 32 c.c. of *N*/2 barium chloride solution and 300 c.c. of recently boiled water, and allowed to stand on the water-bath for three-quarters to one hour. The liquid is then cooled, diluted to a definite volume (500 c.c.), and filtered, and an aliquot portion of the filtrate (100 c.c.) titrated with *N*/2 hydrochloric acid (phenolphthalein as indicator). In some cases the insoluble barium resinate coagulates at the bottom, leaving a clear supernatant liquid which can be titrated without filtration. Simultaneously, a blank test is made and titrated under the same conditions, to make allowance for the possible action of atmospheric carbon dioxide upon the barium hydroxide during the filtration.—C. A. M.

Turpentine; Halogen absorption of —. E. M. Taylor. Analyst, 1919, 44, 401–402.

WHEN iodine (Wijs') solution is used absorption of halogen by turpentine is never complete (see also this J., 1902, 1439; 1904, 302). The author has studied the reaction, using a solution of iodine tribromide in chloroform. In one set of experiments the turpentine was treated with an excess of the reagent for varying lengths of time, in another set varying amounts of reagent were used and the excess of iodine titrated after one minute's contact. The results obtained indicate that the reaction between turpentine and halogen is according to the equation $3\text{C}_{10}\text{H}_{16} + 4\text{IBr}_3 = 3\text{C}_{10}\text{H}_{16}\text{Br}_4 + 2\text{I}_2$, and that there is no intermediate reaction. This reaction can be realised with practically no secondary reaction by adding 10 c.c. of *N*/1 IBr₃ solution in chloroform to 0.1–0.15 gm. of turpentine dissolved in 10 c.c. of chloroform, adding potassium iodide solution within 1 min., and titrating the excess of iodine immediately with thiosulphate solution.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Hevea latex; Natural coagulation of — in the absence of air. W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1919, No. 16, 313—337.

Is a comparison of the product of natural coagulation of undiluted latex in the absence of air with that obtained by coagulation of 15% latex with acetic acid, no practical difference was observable in the inner qualities of the rubber, although the former exhibited somewhat less variation in rate of cure. Factors which affect the rate of cure of rubber prepared by the ordinary method of coagulation, *e.g.*, prolongation of the coagulation period, alteration of the coagulation temperature, and resting of the trees, similarly influence the product of spontaneous coagulation. The addition of small quantities of sugar to the latex to facilitate natural coagulation has no appreciable effect on the rubber. A temperature of 40° C. gives a more satisfactory coagulation process than the 50°—55° C. mentioned by Barrowcliff (this J., 1918, 50 r). The porosity of the natural coagulum somewhat aids crêping, but the crêped material dries more slowly than crêpe from acetic acid coagulum.—D. F. T.

Rubber; Effect of soaking the rolled or unrolled coagulum in water on the properties of the — O. de Vries. Comm. Centr. Rubber Stat., Buitenzorg, 1919, No. 17, 339—373.

THE general effect of soaking the coagulum is an extraction of serum substances causing a loss in weight of 0.2—0.4% for crêpe, 0.5—3% for sheet, and 0.2—2% for unrolled coagulum; this involves a decrease in the rate of vulcanisation. Further soaking causes a "maturing" effect with continued loss in weight, but with increase in rate of vulcanisation, so that the original retardation is diminished or changed into an acceleration. The accelerators formed during "maturing" are only partly extracted by water. Soaking freshly-rolled sheet rubber does not prevent subsequent development of "rustiness," but is of considerable effect in preventing greasiness (due to hygroscopic substances on the surface of the sheet) and in decreasing the liability to develop mouldiness.—D. F. T.

Rubber; Cause of rustiness in sheet — H. J. Hellendoorn. Comm. Central Rubber Stat., Buitenzorg, 1919, No. 18, 119—136.

"RUSTINESS" on the surface of sheet rubber is not caused by the drying of a film of serum substances but is due to the decomposition of serum substances by an aerobic micro-organism; it may be induced by keeping freshly rolled sheets in a moist atmosphere for one or two days, the most favourable temperature being about 40° C. Smoking reduces the tendency to "rust," and the trouble may be inhibited

by treating the surface of the freshly rolled sheet with a disinfectant such as a solution of formalin or bisulphite; the simplest method of prevention, however, is to ensure rapid drying of the surface of the rubber.—D. F. T.

Caoutchouc; Bromination and constitution of — W. C. Schmitz. Gummi-Zeit., 1919, 34, 167—169, 193—195.

THE various and somewhat contradictory results which have been recorded as to the behaviour of rubber towards bromine are probably to be attributed to the interference of colloidal phenomena with the purely chemical stoichiometrical process. In order to avoid this disturbing influence the author has studied the bromination of rubber after a preliminary "depolymerisation" by heat. After the removal of the resinous constituents by prolonged extraction with acetone, the rubber was heated under 15 atm. pressure in an autoclave for 10 hours with xylene of b. pt. 130°—160° C.; the resulting mobile solution readily yielded its insoluble protein and other constituents when centrifuged; the xylene was then removed by distillation and after dissolving in carbon tetrachloride the rubber was submitted to the action of a solution of bromine in the same liquid. The consumption of bromine was in the proportion 5Br:C₂₀H₁₂; in view, therefore, of the addition of a molecule of bromine at each double bond, the molecular weight of the depolymerised hydrocarbon must be at least C₂₀H₁₂, whilst that of the original rubber is presumably much greater. In the course of several hours the reaction liquid developed hydrogen bromide due to elimination of this substance from the soluble primary additive compound, C₂₀H₁₂Br₁₀, with formation of a micro-crystalline insoluble compound, C₂₀H₁₂Br₄; the former is probably an open-chain compound, whilst the latter is possibly cyclic, but with smaller rings than the original rubber, and is quite distinct from the ordinary "caoutchouc tetrabromide." Whether the opening of the cyclic caoutchouc molecule occurs during bromination or is effected already in the depolymerisation process it is at present not possible to decide. Depolymerised rubber is therefore regarded as undergoing bromination as a simple chemical process without any complications due to colloidal phenomena. The results of the investigation are in accord with Harries' more recent views of the constitution of the rubber molecule (this J., 1915, 670).—D. F. T.

Vulcanisation coefficient; Effect of organic accelerators on the — D. F. Cranor. India-rubber J., 1919, 58, 1199—1205.

A MIXTURE of smoked sheet rubber (100), sulphur (6), and zinc oxide (1), when vulcanised over a range of periods between 85 minutes and 235 minutes at 292° F. (144° C.) or 45 lb. steam pressure in a platen press gave a maximum tensile strength with the 190 minutes period, the corresponding coefficient of vulcanisation being 4.76; after an accelerated "ageing" test, however, the product of 130 minutes vulcanisation and coefficient 2.85 had the maximum strength. The latter product is therefore regarded as the "best cured" sample. Other mixtures were then tested, derived from the above by the addition of 0.5 to 1% of an organic accelerator such as hexamethylenetetramine and dimethylammonium dimethyldithiocarbamate. With the former catalyst a vulcanisation coefficient of 2.83 was attained in 50 minutes, whilst the corresponding tensile strength and resistance to stretch were much greater than in the catalyst-free mixing. With the latter accelerator satisfactory physical properties, much superior to those of the "blank" mixing, were obtained after 3, 4, and 5 minutes, the corresponding vulcanisation co-

efficients being 1.09, 1.21, and 1.45. With the unaccelerated mixture, to obtain a product showing 700% elongation at a load of 1000 lb., the presence of about 4.9% of combined sulphur was necessary; with the hexamethylenetetramine and dimethylammonium dimethyldithiocarbamate mixings the corresponding coefficients necessary were 1.8% and 0.9%. Indeed, distinct signs of vulcanisation were visible after the last-mentioned mixture had been merely stored in the dark for a month at the ordinary temperature. The results suggest that the shorter the necessary period of heating for vulcanisation the lower the proportion of combined sulphur required to produce the desired physical condition. Comparable indications were obtained with similar mixings prepared with an inferior brown plantation crêpe, which indeed could not be vulcanised satisfactorily without an accelerator.—D. F. T.

PATENTS.

Rubber; Process for devulcanising —. Devulcanising process and product thereof. Process for devulcanising vulcanised rubber. C. F. Willard, San Diego, Cal. U.S. Pat. (a) 1,322,077, (b) 1,322,151, and (c) 1,322,152, 18.11.19. Appl., (a) 31.5.17, (b) 18.3.18, and (c) 5.12.18.

(a) VULCANISED rubber is boiled with a liquid consisting largely of a viscid, gummy hydrocarbon; this forms a froth on the surface of the liquid and on account of its greater affinity for sulphur under the prevailing conditions, removes combined sulphur from the rubber. (b) Vulcanised rubber is boiled with a viscous mixture of a tar and a flux of a liquid hydrocarbon in the presence of water. (c) More or less of the combined sulphur of vulcanised rubber is liberated by boiling the rubber with an emulsoid colloid solution and a detergent solution.—D. F. T.

[Chrome] leather waste; Process for the utilisation of —. C. Bennert, Grünau, Germany. Eng. Pat. 115,421, 9.4.18. (Appl. 6050/18.) Int. Conv., 30.4.17.

CHROME-LEATHER cuttings are freed from materials and colours used in finishing the leather by treatment at 35° C. with a dilute alkaline solution, agitation with sand, ground pumice or the like, and repeated boiling with water, containing if necessary oxidising or reducing bleaching agents, and are then heated to 75°–80° C. for 2–3 hours with a solution containing 15 parts of sodium hydroxide in 500 parts of water for each 100 parts of the cuttings. After cooling and standing for some time, the mixture is filtered and the liquor is made neutral to phenolphthalein by the addition of acetic or formic acid, and is concentrated to a syrupy consistence. The product contains protalbinic acid, lysalbinic acid, and other similar substances formed by hydrolysis of the leather which possess the property of yielding silver salts capable of keeping silver, silver oxide or hydroxide in colloidal solution, and may be used in cleaning, fulling, and dyeing textile fabrics. Chromium compounds may be recovered from the residue obtained on filtration of the liquor.—L. A. C.

Tanning leather for belts. F. Gilardini, Turin, Italy. U.S. Pat. 1,321,730, 11.11.19. Appl., 21.5.18. (See also Eng. Pat. 114,631; this J., 1919, 297 A.)

XVI.—SOILS; FERTILISERS.

Soil analysis. F. Münster. Landw. Versuchs-Stat., 1919, 94, 181–189.

THE following method of extraction is recommended:—300 grms. of the soil is mixed with 900 c.c. of concentrated hydrochloric acid, and the mixture is shaken every hour for 48 hours; the clear liquid is then decanted, filtered, and 300 c.c. of the filtrate is evaporated, with the addition of ammonium chloride. The residue is moistened with nitric acid, hydrochloric acid is added, and the mixture is again evaporated; this operation is repeated, the residue then dissolved in hydrochloric acid and water, the silica collected on a filter, and the filtrate used for the determination of iron, alumina, calcium, magnesium, potassium, and phosphoric acid.—W. P. S.

Soil-sorption. E. Ramann and A. Spengel. Landw. Versuchs-Stat., 1918, 92, 127–146. (See also J. Chem. Soc., 1919, i., 615.)

THE results of experiments in which an artificial zeolite (permutite, hydrated aluminium alkali silicate) was treated with solutions of neutral potassium, ammonium, calcium, and sodium salts, showed that the interchange of bases which takes place has the character of a chemical exchange; no signs of physical adsorption could be detected. Potassium and ammonium are mutually replaceable, and displace sodium and calcium completely from the zeolite, whereas the displacement of potassium and ammonium by sodium and calcium is incomplete. The ratios between the bases in the solutions and in the zeolite are different; bases present in small proportions in the solution are combined by the zeolite in relatively greater amounts. Within wide limits the absolute concentrations of the salts in the solution are without appreciable influence on the composition of the zeolite, this being the case even with mixtures of calcium salts with those of univalent metals.

—T. H. P.

Copper; Content of — in cultivated soils. L. Maquenne and E. Demoussy. Comptes rend., 1919, 169, 937–942.

THE amount of copper brought into solution by boiling 6 grms. of the soil for half an hour with 50 c.c. of 10% sulphuric acid has been estimated in a number of ordinary arable soils and a number of vineyard soils. With the arable soils the copper content varied from 1 to 50 mgrms. per kilo. of fine soil, but in some of the vineyard soils it rose to 250 mgrms. Despite these high figures, there has not been any indication of a toxic effect of the copper on the vines. Most of the copper is in the surface layer of the soil, the penetration being very slow.

—W. G.

Calcium carbide content of crude calcium cyanamide. V. Maly. Z. Landw. Versuchsw. in Oesterreich, 1916, 19, 445. Bied Zentr., 1919, 48, 369–370.

ALL the samples of crude calcium cyanamide intended for agricultural use which were examined showed a calcium carbide content of under 0.24%.

The carbide content of crude calcium cyanamide filled into sacks was at first 2.7%; it fell after one day to 2.1%, and on the third day was 0.2%. Pipes of varying width and length, closed at one end, were filled with crude calcium cyanamide containing 2.7% of carbide. On the 29th day the carbide content at the closed end of a 15 cm. pipe had sunk to 0.66%, and in a 45 cm. pipe to 1.67%. In both cases the pipes were 3.5 cm. wide, and at the open ends there was found 0.014% of carbide. In layers of material which are not easily accessible to air, the decomposition goes on only very slowly.

—J. H. J.

Calcium cyanamide; Influence of storage on the nitrogen losses and nitrogen changes occurring in crude —. D. Meyer and R. Gorkow. *Illustr. Landw. Zeit.*, 1919, 39, 27—28. *Bied. Zentr.*, 1919, 48, 370—373.

CRUDE calcium cyanamide was spread in a layer 1 cm. thick on glass plates, some of which were kept in a room the temperature of which varied from 7° to 24° C. from winter to summer, and the remainder in a cellar at 6°—18° C. Increases in weight took place after 18—25 weeks' storage of 21—26% during summer and 22% during winter in the room and of 63—65% during summer and 69% during winter in the cellar. Hardly any loss in total nitrogen took place during storage, but there was a considerable decrease in cyanamide nitrogen and an increase in dicyanodiamide nitrogen and in other forms of nitrogen. This was especially marked in the samples stored in the cellar during summer, when about 50% of the cyanamide was converted into dicyanodiamide. It is concluded that calcium cyanamide should be stored in a dry, closed room, and if loose it should be covered with sacking and straw. Paper bags of the material should be stored close together, the spaces being filled with more material and the whole covered with straw.

—J. H. J.

Calcium cyanamide and ammonium sulphate; Influence of iron oxide and common salt upon the fertilising action of —. O. Lemmermann and A. Einecke. *Mitt. Deut. Landw.-Ges.*, 1918, 33, 574. *Bied. Zentr.*, 1919, 48, 290—292.

FIELD experiments were made during two years with the usual fertilisers, to which were added calcium cyanamide and iron oxide, but the addition of the iron oxide failed to produce any better crop than the calcium cyanamide alone. Sodium chloride caused no increased crop when used with calcium cyanamide and ammonium sulphate respectively. Calcium cyanamide containing 10% of soda produced no better results than the ordinary variety, and both were inferior to saltpetre. The crops used were rye, mangolds, and turnips.

—J. H. J.

Peat; Experiments on the action of various fertilisers made from —. B. Tacke. *Mitt. Ver. Förderung der Moor-Kultur im Deut. Reiche*, 1918, 36, 369—373. *Bied. Zentr.*, 1919, 48, 289—290.

For these experiments a special fertiliser was used made from peat and containing ferric salts. Its analysis was: mineral matter 10%, nitrogen 1.5%, lime 12%, potash 0.6%, phosphate 0.5%. Another fertiliser used was humus silicic acid, which had the following composition: mineral matter 30%, nitrogen 0.9%, lime 1.5%, potash 0.3%, phosphate 0.2%. Pot cultures of oats in sand were made, to which were added potassium phosphate, calcium carbonate, and one of the special fertilisers. The crops obtained were poor, as also were those obtained in peat cultures. The peat fertilisers did not appear to have provided any nitrogen for the use of the plants.—J. H. J.

Phosphoric acid; Rate of solution in water containing carbon dioxide of the — present in basic slag and other phosphates. J. G. Maschhaupt Versl. Landbouwk. Onderzoek. Rijkslandbouwproefstat., 1919, 23, Sept. *Chem. Zentr.*, 1919, 90, IV., 866.

THE rate of solution of various phosphates was determined by continuous extraction at 30° C. with water containing carbon dioxide, with a view to testing the theory that the value of a phosphate as a manure depends primarily upon the rapidity with which the compounds taken up by the plants from the moisture of the soil are replaced in solution. The results obtained were somewhat irregular, for example, the rate of solution of Florida phosphate was much greater than that expected, and Algerian phosphate dissolved more rapidly than basic slag.—L. A. C.

Ammonium polysulphide wash. Eyre and others. See XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Frothing of boiling liquids, foam separators, and juice-traps in sugar factories. H. Claassen. *Zentr. Zuckerind.*, 1919, 27, 500—502. *Chem. Zentr.*, 1919, 90, IV., 871—872.

THE particles of liquid escaping from the evaporating pans may exist either as small or large droplets suspended in the vapours or as froth, and the type of trap required to catch them must be differently designed according to their nature. According to whether the bubbles at the surface of the boiling liquid immediately disappear or persist for some time, a distinction is made between non-frothing and frothing liquids. In the case of non-frothing liquids the drops can be trapped simply by providing in the upright evaporators a vapour space 3—4 m. in height, the efficiency of which is increased by one or two baffle plates suitably placed about half-way up. The physical properties of liquids which are the cause of foaming are not well known. Bundles of suitably disposed steam-heated tubes, through which the stream of vapour is led, may constitute a very effective foam destroyer. Less effective is the use of a steam jet in the upper part of the evaporator. A special kind of frothing takes place at the beginning of the boiling; this may be largely prevented by destroying the initial froth by the addition of some fat and then increasing the evaporation by the admission of more heating steam, whereby a stronger circulation of the de-aerated and no longer superheated liquor is induced. Froth separators are apt to be ineffective in cases where frothing is caused by a sudden increase in the vacuum, and it is better in such cases to endeavour to arrive at an arrangement which will ensure more uniform conditions of pressure in

the evaporator plant. Effective froth separators will cause a very considerable loss of heat efficiency (up to 14%), and they should only be installed in cases where they are really necessary.—J. F. B.

Cane sugar; Construction of an autocalculus [nomon] or chart for the indication of commercial —. W. E. Appleby. Chem. Eng. and Min. Rev., 1919, 11, 173–178; 12, 33–38.

THE author anticipated Deming (this J., 1918, 217A) by several years in the principle of the nomon. In 1898 he elaborated a "sucrograph" for the rapid calculation of the results of sucrose determinations by the double polarisation method, whilst, later, he devised graphs for a number of other routine calculations in the factory and laboratory. Instructions are given for the construction of "autocalculus" charts relating to the determination of the "commercial cane sugar" in cane. This value serves for the purchase of cane in Queensland, the method recently prescribed by the Government of that country being as follows:—

$$\begin{aligned} \text{Total soluble solids} \times \frac{100 - (3 + \text{fibre})}{100} &= \text{total soluble solids in the cane.} \\ \text{Sucrose in the juice} \times \frac{100 - (5 + \text{fibre})}{100} &= \text{sucrose in the cane-juice.} \\ \text{Total soluble solids} - \text{sucrose in the cane} &= \text{impurities in the cane.} \\ \text{Sucrose in the cane} - \text{impurities} &= \text{"commercial cane sugar."} \end{aligned}$$

Total soluble solids are found by the Brix hydrometer reading; sucrose by direct polarisation; and the fibre by the diffusion method. The graphic indication of results according to the nomon or autocalculus principle cannot compare in minute accuracy with correct arithmetical or algebraic computation, and the results are neither so exact nor obtained as rapidly as those given by a modern calculating machine. The method is nevertheless of sufficient accuracy for a number of routine calculations.—J. P. O.

Mannitol; Oxidation of — by nitrous fumes. E. Votocék and C. Kranz. Z. Zuckerind. Böhm., 1919, 43, 577–580.

AQUEOUS solutions of mannitol are slowly oxidised by nitrous fumes, yielding a mixture of mannose and hexulose; reaction can be accelerated by the addition of small quantities of a ferrous salt. Nitrous fumes in this case behave like other oxidising agents, yielding a mixture of ketonic and aldehydic products.—H. W.

Starch; Systematic ageing experiments with solutions of various kinds of — under exact time conditions: Time law of the ageing of starch solutions. H. Sallinger. Kolloid-Zeits., 1919, 25, 111–115.

THE ageing of starch solutions at 7° C. has been followed by precipitating the starch gel at various times by means of ptyalin and weighing it after drying at 110° C. If G is the weight of dry gel and t the time of ageing in hours, $G = g t^a$, g and a being characteristic constants for the different kinds of starch. Some values obtained for the constants are shown in the following table:—

	g	a
Soluble potato starch I.	4.06	0.445
" " " " II.	3.00	0.455
Soluble wheat starch	5.37	0.165
Soluble barley starch	11.17	0.214
Amylodextrin from soluble potato starch	3.51	0.521

Sugar beet; New edible product [syrup] and process of obtaining same. P. Kestner, Paris. Eng. Pat. 135,235, 14.9.18. (Appl. 14,969/18.)

A SYRUP free from any unpleasant odour or flavour is obtained from beet juice by treatment in an evaporator (preferably of the climbing film type) in which the temperature is raised by setting up a counter-pressure. If, for example, the desired concentration of the syrup be such that its boiling-point under atmospheric pressure would be 120° C., a counter-pressure is provided sufficient to raise the boiling point to 130° C., but it is essential that the syrup shall not be maintained at this degree for more than a few seconds.—J. P. O.

Sugar solutions; Process for continuous defecation of —. G. B. Williamson, Gramercy, La., Assignor to Industrial Apparatus Corporation, Brooklyn, N.Y. U.S. Pat. 1,317,607, 30.9.19. Appl., 30.4.18.

SUGAR solutions are treated with an acid, neutralised with lime, drained off, aerated, heated to cause the impurities to rise to the surface, and then drawn off from the bottom. (See also Coates, this J., 1919, 872A.)—J. H. L.

[Beet] diffusion battery. J. Masin, Prague. Ger. Pat. 314,200, 19.4.18. Addition to Ger. Pat. 313,433 (this J., 1919, 958A).

IN the middle of each of the vessels of the battery described in the chief patent, in place of the partition, there is a vertical tube, the lower end of which reaches the bottom, while the upper part bends over into the next vessel. Each of these tubes is provided with an injector by means of which the beet slices are forced from one vessel to the next, while the extract is made to pass in the contrary direction from vessel to vessel through suitable overflow tubes. To prevent an excess of juice being carried over with the slices, the bend of each tube is perforated and is surrounded by a jacket connected with the vessel by a return tube. —J. P. O.

XVIII.—FERMENTATION INDUSTRIES.

Alcoholic fermentation; Correlative formation of acetaldehyde and glycerol by the scission of sugar, and new contributions to the theory of —. C. Neuberg and E. Reinfurth. Ber., 1919, 52, 1677–1703.

IN outline, Neuberg's theory is as follows. Sugar is converted into methylglyoxal, which may be hydrated and reduced to glycerol or oxidised to pyruvic acid, this breaking down into carbon dioxide and acetaldehyde, which is reduced to alcohol. In the presence of sulphites, the best being calcium sulphite, as is now shown, the acetaldehyde is fixed, and the available hydrogen works in the direction of the production of glycerol. In fact, practically equimolecular proportions of aldehyde and glycerol are produced, and in the more concentrated solutions the quantitative realisation of the reaction,

has been achieved as well as might be expected of such a biochemical process. This evidence, therefore, strongly supports the theory. (See further, J. Chem. Soc., 1920, i., 124.)—J. C. W.

Alcoholic fermentation; Course of — in presence of calcium carbonate. J. Kerb. Ber., 1919, 52, 1795–1800.

ALCOHOLIC fermentation by pure cultures of yeast proceeds quite normally in the presence of calcium carbonate. The yield of alcohol is practically the

same, and no calcium pyruvate is formed, whereas Fernbach and Schön (this J., 1914, 97, 707) reported the production of a very large quantity of this salt. Probably they used a very impure ferment, and were, therefore, not really studying alcoholic fermentation at all.—J. C. W.

Yeast; Utilisation of amides by —. P. Thomas. Ann. Inst. Pasteur, 1919, 33, 777—806.

UNDER suitable conditions, yeasts are capable of utilising urea and, to a lesser extent, acetamide and its immediate homologues as sources of nitrogen. (See further, J. Chem. Soc., 1920, i, 126.) —W. G.

Diastatic properties of formaldehyde. G. Woker and H. Maggi. Ber., 1919, 52, 1594—1604.

A RECAPITULATION of the evidence on which the authors base their view that formaldehyde resembles diastase in its action on starch (this J., 1916, 1268). Recent criticisms (this J., 1919, 433 A, 508 A) are met by the assumption that the opponents of the theory kept their mixtures too long, for the authors believe that the hydrolytic products are in time rebuilt into non-hydrolysable and non-reducing substances, such as the so-called "reversion dextrin," just as when egg-albumen is digested with papain there is a reversion of the process after a time.—J. C. W.

[Yeast] *Saccharomyces thermantilonum*. H. Euler and I. Laurin. Biochem. Zeits., 1919, 97, 156—170.

THE inversion capacity, the catalase activity, the rate of fermentation at 35°—40° C., and the growth of *S. thermantilonum* have been studied. After the tests the culture showed certain deviations in its behaviour at the characteristic temperatures from the original culture. It is suggested that adaptation may be responsible for this.

—S. S. Z.

Glycerol; Influence of the presence of trimethyleneglycol on the estimation of [fermentation] — by Zeisel's isopropyl iodide method. C. A. Rojahn. Ber., 1919, 52, 1454—1460.

ZEISEL'S method (this J., 1902, 992) is not applicable to the estimation of fermentation glycerol (the German "protol"-glycerol), for this contains trimethyleneglycol, which develops di-iodopropane. This passes over more or less completely with the isopropyl iodide, although its boiling-point is much above the reaction temperature (120°—125° C.).

—J. C. W.

Tyrosinase of potatoes; Separation of — into components. H. Huehn. Ber., 1919, 52, 2029—2041.

POTATO tyrosinase can be separated by ultra-filtration into a thermolabile residue (α -tyrosinase) and a filtrate (activator) which is stable towards heat; when separately tested, neither component shows the tyrosine reaction, but the mixture of the two is again active. The inactive residue can be activated by the addition of the solution obtained by boiling expressed potato juice in dilute acetic acid solution and subsequent filtration, as also by addition of an aqueous solution of the ash obtained by igniting the residue left on the evaporation of such a solution. Toluene appears to act as an oxygen carrier, since the preservation of solutions beneath toluene does not inhibit the enzymic process of tyrosinase as would be expected in consequence of the assumed exclusion of air. Alkaline solutions of pyrogallol become brown when placed beneath a layer of toluene 8 cm. high, and the result is not due to hydroclastic activity of toluene, since the

pyrogallol solutions remain unchanged when the experiment is performed in an atmosphere of hydrogen.—H. W.

PATENTS.

Alcohols; Process and apparatus for continuous rectification of —. E. Barbet et Fils et Cie., Paris. Eng. Pat. 107,975, 4.7.17. (Appl. 9659/17.) Int. Conv., 19.10.11.

XIXA.—FOODS.

Rice; Chemical composition of natural and polished Italian —. I. G. Issoglio, Atti R. Accad. Sci. Torino, 1917-1918, 53, 423—436.

POLISHED rice is very poor in ash and also in total phosphoric anhydride, the phytin phosphoric anhydride being reduced to a minimum.—T. H. P.

Rice; Chemical composition of residues from the treatment of —. II. G. Issoglio, Atti R. Accad. Sci. Torino, 1918—1919, 54, 440—451.

RICE residues derived from the husk are very poor in nutritive substances, whilst those obtained by removal of the outer cortical layers of the corns are very rich in organic and inorganic phosphorus compounds, fats, and proteins, and contain phytin and vitamins. (See J. Chem. Soc., 1920, i, 132.)

—T. H. P.

Moisture content of feeding stuffs; Change in the — by grinding, a source of error in analysis. H. Neubauer. Landw. Versuchs Stat., 1919, 94, 1—8.

EXPERIMENTS made with potatoes and barley showed that when the moisture was determined on the un-ground sample, and on the same sample after grinding to 1 mm. fineness, the moisture was always less in the ground sample, the decrease varying from 1 to 5%. This difference was nearly the same as the loss of weight which occurred when the sample was exposed in a warm room for 24 hours. If the sample was partially dried before grinding, a further loss of moisture equal to the above difference still took place during grinding. The moisture content was determined also at different stages during the grinding process, and it was found that the loss of moisture occurred gradually in each stage. As the other constituents of the feeding stuff are usually determined on the ground sample, it is necessary to make allowance for the change in moisture content.—J. H. J.

Straw fodder; Treatment of — by Beckmann's [alkali] method. G. Fingerling and K. Schmidt. Landw. Versuchs Stat., 1919, 94, 115—152.

IN Beckmann's process of making fodder (see this J., 1919, 384 A, 789 A) straw is simply treated with alkali solution in the cold, and the authors have carried out numerous experiments with the object of ascertaining how the product thus obtained compares with that produced by methods in which the

straw is heated under pressure with alkali. They find that there is no appreciable difference in the digestibility of the two products. The results obtained show that three hours' treatment with 1.5% sodium hydroxide solution yields the best product.

—W. P. S.

Tyrosinase of potatoes. Haebl. See XVIII.

PATENTS.

Chocolate, cocoa butter, or other materials which coagulate when cold; Apparatus for cooling —. E. L. A. Savy, Paris. Eng. Pat. 124,196, 18.2.19. (Appl. 4047/19.) Int. Conv., 13.3.18.

A COOLING chamber is provided with two or more conveyors side by side and with horizontal fans supported on standards both above and below the conveyor. The conveyors may be worked at different speeds. A temperature-adjusting chamber is situated below the conveyors, in which the cooled material is placed and into which air at ordinary temperature is drawn by horizontal fans and caused to pass with a swirling motion over the material, so that its temperature is rapidly raised to that of the atmosphere.—J. H. J.

Hay, straw, and similar forage; Method of treating —. C. J. Coleman and H. G. Jones, London. Eng. Pat. 134,944, 15.11.18. (Appl. 18,787/18.)

THE material to be treated is placed in a revolving drum and heated to 300°–400° F. (about 150°–200° C.) at atmospheric pressure for 20–30 mins., whereby assimilable substances are produced from the starch and cellulose.—J. H. J.

Baking-powder and self-raising flour; Manufacture of — and materials to be used therein. A. E. Berry, Wanstead, and A. Boake, Roberts, and Co., Ltd., Stratford. Eng. Pat. 134,987, 30.11.18. (Appl. 19,815/18.)

PHOSPHORIC acid or a solution thereof is sprayed into agitated flour or other absorbent material, whereby a product which can be used as the acid ingredient of a baking-powder is produced. This product may be mixed with sodium bicarbonate to form a baking-powder, and with flour in addition to form a self-raising flour.—J. H. J.

Proteid substances; Process of manufacturing vegetable —. S. Satow, Sendai, Japan. U.S. Pats. (A) 1,321,479 and (B) 1,321,480, 11.11.19. Appl., 25.11.16.

(A) PROTEIN-CONTAINING material is treated to destroy its cellular structure and to remove oil, after which it is extracted by a liquid without heat, and the protein precipitated from the solution by ferment action. (B) In the preceding process the protein is precipitated by sulphurous acid.

—J. H. J.

Cereal food and process of production. J. L. Kellogg, Battle Creek, Mich. U.S. Pats. (A) 1,321,753 and (B) 1,321,754, 11.11.19. Appl., 10.6.19.

(A) GRAIN is heated at a temperature sufficient to dextrinise starch partially, after which it is slightly dried and formed into separate particles, which are afterwards dried or toasted. (B) In the preceding process the separate particles, which may be in the form of shreds, are subjected to a high temperature, about 400° F. (about 200° C.), for some minutes so as to puff the particles and cook them completely. The preliminary heating may be effected with live steam. The food produced has the characteristic of retaining its puffed form when added to milk.

—J. H. J.

Food product; Process for the production of a — rich in proteins from cereal grains. A. Backhaus. Ger. Pat., 301,365, 22.12.16.

AFTER removing the oil as completely as possible, the grains are heated with a small amount of alkali, dried, and ground. A product of good keeping quality and improved taste, containing about 40% of proteins, is thus obtained. It may be added to other foods, or used as a coffee substitute.

—J. P. O.

Food condiments; Process for the preparation of —. A. Backhaus, Berlin. Ger. Pat. 303,994, 20.4.17.

THE germ of grain, from which the fat and bitter principle have been removed, is treated with acid and submitted to the combined action of proteolytic enzymes and yeast. By this treatment the albuminous matter is dissolved, the starch and sugar fermented, and flavouring substances are formed. The product is filtered and evaporated to any desired consistence.—J. H. J.

Meat-juice preserves; Manufacture of —. Nobel und Co., Hamburg. Ger. Pat. 307,135, 13.5.16.

RAW meat is chopped, partly fine and partly in cubes or irregular pieces, suitable quantities of salt and spices are added, and the meat is then mixed with readily soluble dried milk. The mixture is placed in the containers in which it is to be packed, and exposed to the air at 10°–12° C. for about 24 hours, in order to obtain a uniform distribution of the dried milk throughout the mass and a change of the alkaline reaction to acid, with the liberation of small quantities of gas, after which the containers are sealed and sterilised.—J. F. B.

Bran; Process for the removal of — from whole grain for the purpose of making meal. E. W. Wippermann, Hamburg. Ger. Pat. 313,798, 30.1.16.

WHOLE grain is moistened with water or with 0.5 salt solution and is immediately afterwards roasted, the quantity of water or salt solution used being such that only the outer bran coat is acted upon, whilst the grain proper remains unchanged.

—J. H. J.

Food or fodder from scrap leather; Process for the production of a —. J. G. Bader, Mühlhausen. Ger. Pat. 311,323, 23.3.15.

LEATHER scrap is washed, soaked, treated with milk of lime, again washed and soaked, treated in an acid bath, once more washed, pressed, ground, and dried, and if necessary reduced to a meal.

—J. H. J.

Milk; Device for skimming or creaming —. R. Clavel, Basle, Switzerland. U.S. Pat. 1,323,015, 25.11.19. Appl., 26.11.18.

SEE Ger. Pat. 314,090 of 1918; this J., 1920, 40 A.

XIXB.—WATER PURIFICATION; SANITATION.

Waters; Effect of sea-salt on the pressure of carbon dioxide and alkalinity of natural —. E. B. R. Prideaux. Chem. Soc. Trans., 1919, 115, 1223–1230.

TO determine the effect of carbon dioxide on the alkalinity of sea water, experiments were made in which standard carbonate and bicarbonate solutions were mixed with artificial brine solutions having approximately the composition of sea water, and the alkalinity was determined by comparison with

standard solutions, using phenolphthalein or α -naphtholphthalein as indicator. When the value of R , the ratio of equivalents of alkali to molecules of carbon dioxide, was between 1.08 and 1.12, the alkalinity in the case of fresh water was $p_H=8.9$ and in salt water $p_H=8.1$. All waters of higher alkalinity than $p_H=8.1$ will gain carbon dioxide from the air, and this is true of nearly all surface sea waters. The alkalinity of surface waters cannot fall much below 8.1, for then the pressure of carbon dioxide in the sea becomes greater than that in the atmosphere. The alkalinity of bicarbonated fresh waters is kept at about the same value, $p_H=8$, but in these cases the ratio R is about equal to 1.0. Solutions having the higher ratios, 1.06 to 1.16, found in sea water would contain an appreciable amount of carbonate and could not long exist.

—E. H. R.

Drinking water; Purification of — with *potassium permanganate*. H. Drunk. Veröff. Gebiete d. Milit. Sanitätswesen [66], 1. Chem.-Zeit., 1919, 43, Rep., 270.

THE use of an excess of hydrogen peroxide in the permanganate process of purification is not detrimental, as any remaining over is decomposed by the manganese oxides. Tests on the Berlin Nordkanal water and a well water are reported. The observed increase in the total solids left on evaporation is accounted for by the residue of the purifying material. Iron was completely removed and nitrous acid oxidised to nitric acid. The carbonate hardness was only slightly reduced, and no reduction in lime content was observed. The manganese content was usually considerable. Copper sulphate did not behave as a catalyst, but fixed the potassium ions derived from the permanganate, and thus prevented the water from becoming alkaline. The reaction between copper sulphate, permanganate, and hydrogen peroxide was studied, but a regular course of the reaction was not observed. The manganese content of the water varied. On reducing the proportion of copper sulphate to permanganate, the manganese content of the purified water diminished and the minimum was found when the reagents were in equivalent proportions. When calcium carbonate was added before or during the process, the water was freed from manganese and copper. In general, the process yields clear, sterile, colourless drinking water of undiminished palatability and hygienically satisfactory.—H. J. H.

Eusol; Method for the accurate preparation of —. E. J. Hart. Pharm. J., 1919, 103, 535—536.

THE antiseptic hypochlorite solution for the treatment of wounds usually known as eusol (Rettie, this J., 1918, 237) should not contain an excess of boric acid beyond that required to liberate the hypochlorous acid, otherwise its keeping qualities are impaired and it is more irritating to the wound. A solution of suitable strength containing, when fresh, 0.45% of hypochlorous acid is made by dissolving separately 9.636 grms. of boric acid and 6.132 grms. of calcium hypochlorite (in practice an equivalent quantity of bleaching powder is used and the solution is filtered), each in a sufficient quantity of water to make 500 c.c. of solution, and when cold the two solutions are mixed. The above quantities include the amount of boric acid required to neutralise the calcium hydroxide passing into solution from the bleaching powder.

—G. F. M.

Hydrocyanic acid; Disinfection with —. H. Fühner. Pharm. Zentrbl., 1919, 60, 487—492.

HYDROCYANIC acid vapour has been used for destroying clothes moths, Indian meal moth, etc.,

with satisfactory results. To determine the risk of poisoning when rooms are so treated, the author carried out a disinfection experiment in a sealed room containing upholstered furniture, cushions, clothes, etc., 670 grms. of hydrocyanic acid (from sodium cyanide and sulphuric acid) being liberated in the 425 cb. m. of room space. After 15 hours the room was well ventilated. All moths, flies, etc., in the room were killed, as were also mice and ants placed in cages in the room. All the poison was removed by 10 hours' ventilation, except in the case of the cushions, which retained some of the gas for a considerable time longer.—W. P. S.

Anti-dimming compositions for use in the gas mask. P. W. Carleton. J. Ind. Eng. Chem., 1919, 11, 1105—1111.

EXPERIMENTS with various compositions to prevent the glass or celluloid eyepiece of gas masks from being rendered dim by condensed moisture showed that those made from sulphonated oils gave by far the best results. For use with unventilated gas masks of the English and American type sticks and paste were made in accordance with the following formula:—Turkey-red oil (85%), 100; caustic soda, 15; water-glass, 5; and paraffin oil, 5 parts, but subsequently sodium carbonate was used in place of caustic soda owing to the action of the latter on the hands of the workpeople. The product contained from 10% to 20% of moisture. In the case of the French ventilated "Tissot" masks an addition of glycerin was necessary, and the composition was made according to the following formula:—Turkey-red oil (85%), 100; caustic soda, 15 (subsequently replaced by sodium carbonate); water-glass, 5; paraffin oil, 5; and glycerin, 23 parts. In each case a little of the composition was applied to the glass or celluloid, and the latter then polished gently with a rag.—C. A. M.

Anti-dimming preparations for gas masks. H. N. Holmes, F. F. Jewett, G. Leavell, D. Bailey, and E. Shaver. J. Ind. Eng. Chem., 1919, 11, 1111—1116.

COMPARATIVE tests for anti-dimming preparations are described. The requirements of a good preparation are that it should lower the surface tension of water to a pronounced extent, that it should be soluble, but not too soluble, or it will not be retained by the glass, and that it be sufficiently deliquescent to prevent drying. Alkali soaps of unsaturated fatty acids have a much greater power of forming films than those of unsaturated fatty acids. The action of soaps in general is improved by the addition of a small percentage of glycerin, 10 to 15% of sodium hydroxide, and a small amount of "marine oil," with the addition of a small quantity of water-glass as a binding agent. The addition of paraffin oil recommended by other workers is not advantageous. Sulphonated oils made from castor, cottonseed, rape, maize, linseed, and olive oils and from olein all gave excellent results, which proved that the hydroxy group (present only in castor oil) is not a main factor in the process. The alkali salts of sulphonated saturated fatty acids are also effective. There is little difference in the effects of different alkali soaps of sulphonated oils, although the potassium soap of sulphonated cottonseed oil gave better results than the sodium soap. The preparations made in accordance with the following formulae are stated to be decidedly better than the official (U.S.A.) products:—*Sulphonated rape oil*: Sodium salt of 65% sulphonated rape oil (35% H_2O), 100; sodium hydroxide, 20; water-glass, 5; glycerin, 3; and "marine oil," 3 parts. *Sulphonated cottonseed oil*: Potassium salt of 62% sulphonated cottonseed oil (38% H_2O), 100; sodium hydroxide, 15; water-glass, 3; glycerin, 3; and "marine oil," 3 parts.

In both cases these are dried to form solid sticks when compressed. The "mariae oil" (Standard Oil Co.) was probably a mixture of blown rape oil and heavy mineral oil; it had fairly good film-forming properties by itself.—C. A. M.

Ammonium polysulphide wash. J. V. Eyre, E. S. Salmon, and L. K. Wormald. J. Bd. Agric., 1919, 26, 821—822. (See also this J., 1919, 335 A.)

EXPERIMENTS showed that a wash containing 0.11% of polysulphide sulphur was fungicidal to the conical stage of hop mildew (*Sphaerotheca humuli*). A new method of preparing a concentrated ammonium polysulphide wash is as follows: A current of hydrogen sulphide is passed through a mixture of 1 litre of ammonia solution (sp. gr. 0.880), 300 c.c. of distilled water, and 400 grms. of flowers of sulphur until all the sulphur is dissolved. This takes 46—47 hrs., and the mixture should be shaken occasionally. To the dark red liquid 250 c.c. more of ammonia solution is added. This liquid forms the stock solution. It contains 6.5% of sulphide sulphur and 21.9% of polysulphide sulphur. For use, $\frac{1}{2}$ gal. of the stock solution is poured into a solution of 5 lb. of soft soap in 99 $\frac{1}{2}$ gals. of water. This mixture forms the dilute wash and contains 0.5% of soap and 0.11% of polysulphide sulphur. Two applications of the wash should be given at intervals of 7 or 10 days.—J. H. J.

Chloropicrin; Influence of temperature and other physical agents on the insecticidal power of —. G. Bertrand, Brocq-Roussau, and Dassonville. Comptes rend., 1919, 169, 1059—1061.

In the use of chloropicrin against insects, light and the moisture content of the air have no influence on the result, but the temperature plays an important part. Over the temperature range 10°—30° C. the temperature coefficient of the velocity of action is 2—2.5.—W. G.

PATENTS.

Gas; Apparatus for measuring out charges of — [e.g. for sterilising water]. S. H. Menzies and H. J. Magrath, London. Eng. Pat. 134,615, 5.11.18. (Appl. 18,114/18.) (See also Eng. Pat. 121,521; this J., 1919, 63 A.)

A CYLINDRICAL measuring cylinder communicates at the top through a diaphragm with a pressure gauge and is closed at the bottom by a cap. The cap may vary in size so as to vary the capacity of the cylinder, and may carry bars to project into the cylinder and thus reduce its capacity. The cylinder communicates by narrow passages on each side with a paired valve apparatus, acting as inlet and outlet valves. The inlet valve is operated by a push plunger which impinges on a diaphragm connected by rods to a needle valve, which admits gas from a pressure reservoir. The gas first passes through a porous plug so as to equalise the rate of flow. The measuring cylinder is allowed to fill with the gas to the pressure desired, as indicated on the pressure gauge above the cylinder. The push plunger is then released and the one on the exit valve operated, which allows the gas to leave the measuring cylinder and to pass by a pipe to the liquid to be charged. The apparatus is specially suited for measuring a noxious gas, such as chlorine, for the treatment of water for sterilising purposes.—J. H. J.

Sterilising and drying animal and vegetable matter, including slaughter-house offal; Process for —. J. C. Marshall, Manchester. Eng. Pat. 133,983, 23.8.18. (Appl. 13,774/18.)

PIPES, arranged horizontally in series and spaced apart, are supported above the floor of a drying-room. Several such horizontal layers of pipes are arranged one above the other. All the layers are

supplied with valves and are jointly connected to a steam supply or a hot-air supply. The material to be dried is spread in a layer three or more inches deep on the pipes. As the material dries it falls through the spaces between the pipes.—J. H. J.

Liquids; Treatment of —. W. S. Elliott, Pittsburgh, Pa. U.S. Pat. 1,321,999, 18.11.19. Appl., 31.3.15.

LIQUID to be treated is heated and introduced into a chamber in which a partial vacuum is maintained, so that the entering liquid is caused to boil violently, whereby all dissolved gases are evolved and also scale-forming substances are precipitated.—J. H. J.

Liquids [containing phenolic substances]; Purification of —. (A) C. A. Basore, (B) H. S. Davis and S. D. Semenow, and (C) E. A. Dieterle and S. D. Semenow, Assignors to The Koppers Co., Pittsburgh, Pa. U.S. Pats. (A) 1,323,239, (B) 1,323,251, and (C) 1,323,256, 2.12.19. Appl., 15.2.19.

LIQUIDS containing phenolic bodies, such as waste ammonia still liquors, are clarified and filtered through a bed of (A) animal charcoal, (B) a phenol-absorbing humus material, such as ground lignite, or (C) peat. Animal charcoal after use may be re-charred and used for the treatment of more liquid.—L. A. C.

Germicide solution and method of making the same. C. A. Weeks, Philadelphia, Pa., U.S.A. Eng. Pat. 134,880, 11.10.18. (Appl. 16,606/18.)

CHLORINE gas is bubbled upwards through a tall column of eucalyptus oil or eucalyptol kept at 100°—125° F. (38°—52° C.). Hydrochloric acid is formed, and its escape from the oil is facilitated by passing in air or ozone. The treatment is continued until the oil contains 3% Cl, corresponding to the formula $C_{10}H_{17}OCl_2$. Hydrochloric and other acids are also present. The product is an oily liquid of sp. gr. 1.2, soluble in paraffin, alcohol, and ether, and miscible with water. For use, the oil is mixed with water in the proportion of $\frac{1}{2}$ —2 drachms of oil to 1 gal. of water.—J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Chelidonium alkaloids. J. Gadamer. Arch. Pharm., 1919, 257, 298—303.

ON the basis of the results obtained by the author, structural formulae are proposed for chelidonine and α - and β -homochelidonines. (See also J. Chem. Soc., 1920, i., 75.)—T. H. P.

Cervine and sabadinine. K. Hess and H. Mohr. Ber., 1919, 52, 1984—1988.

INVESTIGATION of the alkaloids themselves, of their hydrogen sulphates, potassium salts, aurichlorides, hydrochlorides, and monobenzoyl-derivatives, shows them to be identical. The formula is $C_{22}H_{43}O_8N$. Certain corrections of the data recorded in the literature are given. The alkaloid crystallises with 3.5 mols. H_2O , m. pt. 110° C. The hydrogen sulphate (+2.5 H_2O) has m. pt. 250° C. (decomp.) after becoming discoloured at 210° C. The hydrochloride forms anhydrous needles, m. pt. 247° C.—H. W.

Ormosine and ormosinine, two new alkaloids from Ormosia dasycarpa. K. Hess and F. Merck. Ber., 1919, 52, 1976—1983.

ORMOSINE has been isolated previously by Merck (Wiss. Abhandl. Gebiete Pharm., 1888, No. 22, 346) from *Ormosia dasycarpa*, Jack., a leguminous

plant growing in Venezuela. Its physiological relationship to the morphia alkaloids has been demonstrated by Harnack (Kobert's Jahresber. Fortschr. Pharm., 1881, 1, 59). The authors find that it is not related chemically to these substances, and, indeed, occupies a unique position among alkaloids. In addition, they have isolated ormosinine from the same source, the yield of the former amounting to 0.15%, and of the latter to 0.023%, of the dried seeds. These substances, however, only represent a fraction of the total alkaloid content. The alkaloids are isolated by extracting the crushed seeds with alcohol, evaporating the solvent in a vacuum, and extracting the residue with water; the aqueous solution is made alkaline with ammonia, and shaken with ether. The ethereal solution is agitated with powdered sodium carbonate, after which the solvent is removed, leaving a crystalline residue, from which ormosinine is isolated by taking advantage of its sparing solubility in alcohol, whilst ormosine separates from the alcoholic solution on addition of water. Ormosine, $C_{26}H_{41}N_3$, crystallises (with 3–4 H_2O) in long needles, m. pt. 85° – 87° C., and is readily soluble in alcohol or chloroform. When preserved over sulphuric acid, it loses its water of crystallisation, and forms a colourless gummy mass, which again becomes crystalline when brought into contact with water. At 100° C. it is converted into a viscous oil which does not recombine with water. Ormosinine, $C_{26}H_{41}N_3$, crystallises in well-defined anhydrous cubes and short prisms, m. pt. 203° – 205° C. It is probably the anhydrous form of ormosine.—H. W.

Aloes; Chemistry and pharmacology of —. Products of the oxidation of the constituents of aloes by alkali persulphate, Caro's acid, and hydrated sodium peroxide. E. Seel. Arch. Pharm., 1919, 257, 212–228, 229–254, 254–259.

THE products obtained on oxidising aloin, aloëtin, and the crude resin of aloes have been separated, and the physiological actions of certain of them investigated. (See also J. Chem. Soc., 1920, i., 67, 68, 69.)—T. H. P.

Athaea [marsh mallow] root; Some components of —. O. von Friedrichs. Arch. Pharm., 1919, 257, 288–298.

MARSH mallow root contains 1.7% of an oil, composed of palmitin and olein; butyric acid; a phytosterol, apparently identical with sitosterol; a hydroxy-acid of high molecular weight; an odorous substance of unknown composition; a lecithin containing palmitic and oleic acids and with a basis of choline; 10.2% of sucrose and 0.78% of invert sugar; a mucilage, $(C_6H_{10}O_5)_n$, consisting of glucosan (64%) and xylan; and another saccharo-colloid giving *d*-galactose on hydrolysis.—T. H. P.

Xanthosterol, a crystalline compound from the bark of Xanthoxylum Budrunga. H. Dieterle. Arch. Pharm., 1919, 257, 260–263.

THE bark of *Xanthoxylum Budrunga* contains about 0.25% of an alcoholic compound, $C_{27}H_{48}O$, related to lupeol and alstol, and named xanthosterol by the author. Its reactions and certain of its derivatives are described. (See also J. Chem. Soc., 1920, i., 42.)—T. H. P.

Cholesterol; Transformation of — into cholic acid. A. Windaus and K. Neukirchen. Ber., 1919, 52, 1915–1919.

THE saturated hydrocarbon, cholestane, $C_{27}H_{48}$, obtained by the chemical reduction of cholesterol, is oxidised by chromic acid to an isomeride of cholic acid, $C_{27}H_{46}O_2$, which differs from cholic acid, $C_{27}H_{46}O_2$, in having three hydrogen atoms for the three hydroxyl groups. ψ -Cholestane, which is the saturated hydrocarbon of coprosterol, the

bacterial reduction product of cholesterol, gives true cholic acid on oxidation. This shows that cholic acid has the same carbon skeleton as cholesterol, except that this has an extra isopropyl group, since it yields acetone on oxidation whilst the cholic acid derivatives do not. (See further, J. Chem. Soc., 1920, i., 11.)—J. C. W.

Novocaine; Aromatic analogues of —. J. von Braun and G. Kirschbaum. Ber., 1919, 52, 2011–2015.

IT has been recently shown by Fränkel and Cornelius (Ber., 1918, 51, 1654) that derivatives of primary β -aminoethyl alcohol, in contrast to the tertiary *N*-dialkylated alkamine derivatives (stovaine, novocaine) do not possess anaesthetic action. The compounds which they have examined, however, contain an acyl residue attached to the nitrogen atom in place of the alkyl radical of novocaine, and thus do not belong to quite the same type. Closer analogy is shown by a series of substances which are now described in which a phenyl or substituted phenyl group is introduced in place of one of the alkyl groups. It is found that the aromatic substitution at the nitrogen atom of novocaine is without influence on its anaesthetic power if the basicity of the molecule is also suitably increased. *N*-methyl-*N*- β -benzoyloxyethyl-*p*-phenylenediamine, $NH_2 \cdot C_6H_4 \cdot N(CH_3) \cdot CH_2 \cdot CH_2 \cdot O \cdot CO \cdot C_6H_5$, long slender needles, m. pt. 56° C., is obtained by reduction of the corresponding *p*-nitroso compound, pale green powder, m. pt. 90° C. Sodium *p*-nitrobenzoate reacts readily with β -chloro- or β -bromoethylmethylaniline yielding *N*-methyl-*N*-[β -*p*-nitrobenzoyloxyethyl]-aniline,

yellow needles, m. pt. 70° C., which is reduced to *N*-methyl-*N*-*p*-aminobenzoyloxyethylmethylaniline, colourless leaflets, m. pt. 112° C. When the solution of the latter in dilute hydrochloric acid is treated with sodium nitrite, it yields the corresponding *p*-nitroso-derivative, m. pt. 105° – 106° C., which is almost quantitatively reduced by stannous chloride to *N*-methyl- β -*p*-aminobenzoyloxyethyl-*p*-phenylenediamine,

m. pt. 98° C. Sodium 3,5-dinitrobenzoate and chloroethylmethylaniline yield *N*- β -3,5-dinitrobenzoyloxyethylmethylaniline, m. pt. 121° C., which is normally reduced to the corresponding diamino compound, m. pt. 80° C.—H. W.

Anaesthetics Local —. L. Launoy and Y. Fujimori. Comptes rend. Soc. Biol., 1919, 82, 732–736. Chem. Zentr., 1919, 90, III., 831.

THE benzoyl derivatives of a number of amino-alcohols of the formulae, $(CH_3)_2N \cdot CH_2 \cdot CR(OH) \cdot CH_3$, and $(CH_3)_2N \cdot CH_2 \cdot CH_2 \cdot CH(OH)R$, were examined in respect to their toxicity, their haemolytic action on red blood corpuscles, and their anaesthetic properties. Of the first series, to which stovaine belongs, the benzoyl derivatives of 2-methyl-, 2-ethyl-, 2-amyl-, 2-phenyl-, and 2-benzyl-propanol were investigated, and of the second series the derivatives of 3-ethyl- and 3-amyl-propanol. The derivatives of the second series were less toxic than those of the first, whilst those of the alcohol containing five carbon atoms were the most poisonous. Of the aromatic derivatives the benzyl-propanol derivatives were more toxic than the corresponding phenyl compounds. The haemolytic action on red blood corpuscles increased with increasing molecular weight; it appeared also to increase with increasing separation of the hydroxyl and amino groups. The anaesthetic action of the tertiary alcohols is superior to that of the secondary, and the maximum is attained with the C_5 alcohols.

—G. F. M.

Paracymene. III. Preparation of 2-chloro-5,6-dinitrocymene. H. A. Lubs and R. C. Young. *J. Ind. Eng. Chem.*, 1919, 11, 1130—1133.

THE nitration of 2-chloro-*p*-cymene does not result in the simple formation of dinitrocymene; the principal product is 2-chloro-5,6-dinitro-*p*-cymene, whilst an isomeric compound, not yet isolated, also appears to be formed. A small amount of another dinitrochloro compound (m. pt. 90°—91° C.), containing less carbon than dinitrochlorocymene, is also produced, together with a small quantity of another compound, possibly a chloroterephthalic acid.—C. A. M.

Tetrachlorodinitroethane. W. L. Argo, E. M. James, and J. L. Donnelly. *J. Phys. Chem.*, 1919, 23, 578—585.

ALTHOUGH wrought iron satisfactorily withstands the action of a mixture of dry liquid nitrogen tetroxide and tetrachloroethylene, it is in practice impossible completely to exclude moisture. A porcelain-lined autoclave is therefore more suitable for the production of tetrachlorodinitroethane, the mixture being heated at 80° C. for three to six hours. It is important that the nitrogen tetroxide be dry and be present in excess in the liquid form. (See further, *J. Chem. Soc.*, Feb., 1920.)—J. K.

Nitro-compounds; Influence of the position of substituents on the behaviour of aromatic — in the Kjeldahl estimation of nitrogen. B. M. Margosches and E. Vogel. *Ber.*, 1919, 52, 1992—1998.

THE behaviour of the isomeric nitrophenols, nitrobenzoic acids, and nitrobenzaldehydes when treated with sulphuric acid and potassium sulphate has been investigated. The nitrogen content of the *ortho*-derivatives can be estimated accurately in this manner, but the results for the *meta*- and *para*-compounds are much too low. The favourable influence of the hydroxy- or alkoxy-group in the *ortho*-position to the nitro-group is further shown by the fact that the process gives exact results with 2-nitroresorcinol, 3-nitro-*p*-cresol, and *o*-nitrophenetol, but low results with *p*-nitrophenetol. The presence of *o*-nitrophenol or of *o*-nitrobenzoic acid has a favourable influence on the behaviour of the corresponding *meta*- and *para*-derivatives, and this action cannot be ascribed solely to their content of phenol or benzoic acid. The use of salicylic acid appears particularly advantageous in the case of *meta*-compounds. It is somewhat remarkable that the three nitrocinnamic acids give accurate results. A further series of estimations is recorded with 2,4-dinitrophenol, 2,4-dinitro-*a*-naphthol, 2,4-dinitrobenzoic acid, 2,4-dinitrotoluene, 3,5-dinitrobenzoic acid, 2,6-dinitrotoluene, and 2,4,6-trinitrophenol; the results are considerably low in every case, although concordant amongst themselves. The facts, however, that the 2,4-dinitro-compounds give higher values than the corresponding 3,5- or 2,6-dinitro-derivatives and that 2,4-dinitrophenol gives results almost identical with those obtained with 2,4-dinitrotoluene are in accordance with the observations made with the mononitro-compounds.

—H. W.

Halogen attached to a ring carbon atom; Replacement of — by other substituents. I. Replacement by the carbonyl group. K. W. Rosenmund and E. Struck. *Ber.*, 1919, 52, 1749—1756.

HALOGEN atoms in cyclic compounds can be directly replaced by carboxyl groups by heating the compounds with aqueous or dilute alcoholic potassium cyanide and a little euprous cyanide, for some hours at about 200° C. in strong tubes. Good results have been obtained with halogen derivatives of benzene (mono- and di-), toluene, aniline, nitro-

benzene, phenol, carboxylic acids, naphthalene, and thiophen. (See further, *J. Chem. Soc.*, 1920, i., 44.)
J. C. W.

Aldehydes; New method of converting carboxylic acids into —. A. Sonn and E. Müller. *Ber.*, 1919, 52, 1927—1934.

THE replacement of the chlorine atom of anilide-imido-chlorides by hydrogen is readily effected by the action of an ethereal solution of pure stannous chloride containing the requisite quantity of hydrogen chloride; the tin double salts of the corresponding Schiff's bases appear to be formed as intermediate products, and these pass readily into aldehydes and aniline salts when heated with dilute acids or, in certain cases, when simply treated with steam. The preparation of benzaldehyde, cinnamaldehyde, *p*-hydroxybenzaldehyde, and 3,4,5-trimethoxybenzaldehyde in this manner from the anilide-imido-chlorides of the corresponding carboxylic acids is described, the yields being very satisfactory. The method does not appear to be applicable to the preparation of aliphatic aldehydes. (See also *J. Chem. Soc.*, 1920, i., 58.)

—H. W.

Acrolein; Stabilisation of —. IV. Compounds acting as stabilisers against the formation of desacryl (insoluble resin). C. Moureu, C. Dufrasse, and P. Robin. *Comptes rend.*, 1919, 169, 1068—1072. (See this *J.*, 1919, 923 A.)

Benzoic acid is present in certain of the fractions obtained in the fractional distillation of acrolein and exerts a marked but variable stabilising action. Phenol is also present, but is only a feeble stabilising agent.—W. G.

Arsenic acid; Action of — on polyhydric phenols. A. Sonn. *Ber.*, 1919, 52, 1704.

POLYHYDRIC phenols suffer oxidation when heated with arsenic acid in the usual way, but if pyrogallol and dilute arsenic acid solutions are concentrated in a vacuum and left in the cold, a crystalline acid of the formula $O:As[O:C_6H_3(OH)_3]$ is deposited.

—J. C. W.

Aromatic selenium compounds; Simple and convenient way to prepare —. A. Schoeller. *Ber.*, 1919, 52, 1517—1518.

DIAZONIUM salt solutions react with alkali polyselenides to form organic selenides and sometimes diselenides. The reagent is obtained by fusing black selenium with potassium hydroxide and dissolving the product in ice-cold water. The use of hydrogen selenide is thus unnecessary. (See further, *J. Chem. Soc.*, 1920, i., 41.)—J. C. W.

Thallium; Use of — in organic chemistry. K. Freudenberg and G. Uthemann. *Ber.*, 1919, 52, 1509—1513.

THALLIUM hydroxide or carbonate is useful in the isolation of acids of the gallie acid series. Uric acid, phthalimide, and lactulose also give well-defined thallium salts. Glycine may be prepared from the hydrochloride of its ester by boiling with thallium carbonate and water, filtering the precipitate of thallium chloride, saturating with hydrogen sulphide, and filtering again. (See further *J. Chem. Soc.*, 1920, i., 17.)—J. C. W.

Fluorine; Action of — on organic compounds. B. Humiston. *J. Phys. Chem.*, 1919, 83, 572—577.

THE action of fluorine on organic compounds is usually violent, leading to decomposition. Saturated hydrocarbons are ignited with incandescence and formation of free carbon, fluorides of carbon, and hydrofluoric acid. The behaviour of charcoal ("filthchar"), selenium, acetone, chloroform, phos-

gene, carbon monoxide, carbon tetrachloride, and tetrachloroethylene was also investigated. (See further J. Chem. Soc., Feb., 1920).—J. K.

Ichthyol oils. Scheibler. See IIa.

PATENTS.

Ethyl acetate; Manufacture of — from acetaldehyde. Konsortium für elektrochemische Industrie, Munich. Ger. Pat. 314,210, 27.10.14.

THE catalytic action of aluminium alkyl-oxide (alcoholate) on the conversion of acetaldehyde into ethyl acetate (see Eng. Pats. 26,825-6 of 1913; this J., 1914, 666) is aided by the presence of small quantities of substances which, by themselves, effect the conversion of the aldehyde into paraldehyde or into alcohol. When present to the extent of 5% calculated on the acetaldehyde, aluminium alkyl-oxide gives rise to a 15% yield of ethyl acetate; in the additional presence of small quantities of the following substances the yields are as bracketed:—2% of aluminium chloride (80%); 1% of benzenesulphonic acid (61%); 1.5% silicon chloride (63%); 40% anhydrous copper sulphate (50%); 0.4% sodium hydroxide (56%); 0.4% calcium hydroxide (55%); 0.1% sodium acetate (47%); 0.4% sodium cyanide (77%).—D. F. T.

Erythrene; Purification of —. I. Ostromisslensky, Moscow. Ger. Pat. 314,364, 13.5.14.

CRUDE erythrene, e.g., that obtained by dehydration of 1,3-butyleneglycol, can be purified by treatment with a neutral oxidising agent such as benzoyl peroxide or barium peroxide, or with an alkaline oxidising agent consisting of a mixture of barium peroxide and sodium.—D. F. T.

Monochloroacetic acid; Continuous process for preparation of — from trichloroethylene. A. Guyot, Salindres, Assignor to Comp. des Prod. Chim. d'Alais et de la Camargue, Paris. U.S. Pat. 1,322,898, 25.11.19. Appl., 21.9.18.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Papers; Measuring the gloss of photographic —. K. Kieser. Z. angew. Chem., 1919, 32, 357-359.

THE method proposed is based upon the fact that the light reflected from non-metallic surfaces is plane-polarised in proportion to the degree of gloss of the reflecting surface. A suitable instrument is the Martens' polarisation-photometer which constitutes the upper portion of the Schmidt and Hensch densimeter. If the two slits through which the light enters for the estimation of the density or degree of blackening be replaced by a single central opening, the Martens' photometer is converted into a polarimeter, resembling the old Cornu polarimeter. The rotation of the analyser Nicol is the measure of the polarisation, and the percentage of polarised light in the total light is proportional to the tangent of the angle of rotation. The light must fall on the surface of the paper at an angle of 56° and the polarimeter must be directed towards the paper also at that angle; the line of demarcation of the two halves of the field of observation of the polarimeter will then lie in the same plane as the incidence of the light. Complete polarisation will correspond to a rotation of the analyser through 45°. The best source of light is an electric incandescence lamp controlled by a variable resistance and provided with a depolarising matt

screen; a dark-room is unnecessary. Papers are always examined undeveloped, washed, and dried; it is very important that they should not be "fogged," since a slight greyness considerably increases the degree of polarisation. A slight coloration does not interfere, but with pronounced colours values which are much too high are obtained and the two halves of the observation field are differently coloured. Matt gelatin photographic papers give a value of about 10°, highly glazed ones about 30°, which is about the same as that of white enamelled glass. The method is capable of being used for the determination of the gloss of ordinary white papers which show values between 3° and 12°; moreover, it is capable of showing much finer differences than can be detected by an experienced eye.—J. F. B.

PATENT.

Coloured motion-pictures; Method and apparatus for producing —. W. V. D. Kelley, Brooklyn, N.Y., Assignor to Prizma Inc. U.S. Pat. 1,322,794, 25.11.19. Appl., 12.7.15.

A PART of each of a series of motion-pictures is obtained by open exposure, i.e., without the interposition of the colour-filter which is used for the rest of the picture.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Trinitrotoluene; Oxidation in the manufacture of —. A. S. Eastman. J. Ind. Eng. Chem., 1919, 11, 1124.

IN the nitration of toluene the high temperature at which the process is carried out causes a considerable oxidation of the nitrotoluenes, with a corresponding decrease in the yield of TNT. The spent acid contains about 18% HNO_2 , whilst the nitrator contains a mixture of the various isomeric di- and trinitrotoluenes, and, in one experiment, 2,4-dinitrobenzoic acid was isolated. The following method of determining the total organic acids formed by oxidation of the methyl group has been devised: Nitric acid is removed by evaporation, and sulphuric acid by neutralisation with barium hydroxide and separation of the barium sulphate, the filtrate then containing the soluble barium salts of the organic acids, carboxylic acids formed by oxidation of the methyl group of the toluene, and sulphonic acids produced during the nitration. The barium salts of the organic acids are determined by evaporating an aliquot part of the filtrate and weighing the dry residue of barium salts. The residue is then ignited and the resulting mixture of barium carbonate and sulphate weighed, treated with hydrochloric acid to remove the carbonate, and the residue of barium sulphate weighed. From these data the loss of toluene due to sulphonation and oxidation to carboxylic acids can be calculated, whilst the loss on igniting the dry barium organic salts represents the total loss of toluene (e.g., 1.86%). This would only account for a small proportion of the HNO_2 present. In the nitration of dinitrotoluene ("bi-oil") to TNT, carbon dioxide, carbon monoxide, and oxygen are evolved, the two former in a proportion sufficient to lower the yield of TNT by about 5%, or more than a third of the total loss in the whole process. The composition of the gas may vary considerably, even in the course of a single nitration, and under certain conditions the proportion of carbon monoxide may be so high that the gas mixture becomes explosive. This may account for various explosions in TNT nitrators in which the top of the vessel has been blown off without exploding the charge of TNT.—C. A. M.

Nitrotoluenes; Studies on the —. III. Binary systems of the components p-nitrotoluene, 1,2,4-dinitrotoluene, and 1,2,4,6-trinitrotoluene. J. M. Bell and C. H. Herty, jun. J. Ind. Eng. Chem., 1919, 11, 1124–1127.

SYNTHETIC mixtures of pure p-nitrotoluene (MNT), 1,2,4-dinitrotoluene (DNT), and 1,2,4,6-trinitrotoluene (TNT) were prepared, and the m. pts. of two-component systems of these were determined by the melting point method, and plotted in curves. The most probable value for the m. pt. of MNT was found to be $51.5^{\circ} \pm 0.3^{\circ}$ C., for DNT $69.6^{\circ} \pm 0.3^{\circ}$ C., and for TNT $80.35^{\circ} \pm 0.3^{\circ}$ C. In the binary system MNT–TNT the eutectic points were 33.85° – 33.95° C. (with MNT as solid phase) and 33.7° – 34.2° C. (with TNT as solid phase); in the system DNT–TNT the eutectic points were 45.4° – 45.6° C., and in the system MNT–DNT, 26.44° – 26.54° C. The freezing points of the respective mixtures of from 0 to 100% TNT are given in tables and graphically. (See also J. Chem. Soc., Feb., 1920.) —C. A. M.

Nitrotoluenes; Studies on the —. IV. The three-component system: p-nitrotoluene, 1,2,4-dinitrotoluene, 1,2,4,6-trinitrotoluene. J. M. Bell and C. H. Herty, jun. J. Ind. Eng. Chem., 1919, 11, 1128–1130.

IN a ternary mixture there are three freezing points; the first that at which the first solid appears, the second at which the second solid appears, and the third eutectic point, at which all three solids are in equilibrium with the melted mass or eutectic mixture. In the case of the primary and secondary freezing points in the above-mentioned ternary system, there was often great supercooling when DNT was the solid to be separated, and seeding with small crystals was then required. Curves have been constructed from the data obtained with different mixtures, each containing 10% DNT, with the percentages of TNT as abscissae, and these have been plotted on the conventional triangular diagram. By a method of interpolation both the composition and temperature of points on the boundary curves may be found. By this means it is possible to identify an unknown mixture of these three components, the primary and secondary freezing points, and then the identity of the solid phases being determined, and reference made to the diagrams to locate the composition point. (See also J. Chem. Soc., Feb., 1920.)—C. A. M.

Petroleum spirit; Preparation of trinitrotoluene from —. E. Berl and F. Ziffer. Petroleum, 1919, 14, 1213–1217. Chem. Zentr., 1919, 90, IV., 797.

A PETROLEUM spirit of Galician origin yielding by distillation about 90% between 85° C. and 125° C. gave on nitration about 9% of pure mononitrotoluene, corresponding to 6% of toluene in the petroleum spirit. As nitration of the petroleum spirit on the large scale was impracticable, extraction with liquid sulphur dioxide was tried. The extract obtained amounted to 18.5%, had sp. gr. 0.810, and could be separated by distillation on the large scale into fractions of higher and lower density. In this manner a toluene fraction, composed of 60% of toluene and 40% of petroleum spirit, was obtained, which, after being washed with sulphuric acid to remove olefines, was nitrated to mononitrotoluene. The yield of toluene from the crude oil amounted to 0.162%.—T. St.

XXIII.—ANALYSIS.

Distillation in a high vacuum [; Laboratory apparatus for —]. J. Houben. Ber., 1919, 52, 1460–1462.

THE apparatus, which has a suitable attachment immersed in liquid air, is filled with carbon dioxide and evacuated by a water pump, and during the distillation the gas is allowed to enter through a fine capillary below the surface of the liquid to ensure steady boiling. A pressure of 0.12 mm. is easily maintained.—J. C. W.

Homogeneous liquid mixtures; Apparatus for rapid preparation of —. P. Jolibois. Comptes rend., 1919, 169, 1095–1098.

A SIMPLE apparatus is described and illustrated by means of which a homogeneous mixture may be obtained with two miscible liquids in 1/100th of a second. It consists essentially of two containers, one for each liquid, arranged so as to deliver the liquids at a uniform rate and in the requisite proportions, one to each of the inclined limbs of a Y-tube. The diameter of the Y-tube is 6.2 mm., and the lower vertical limb has a constricted portion 1.5 mm. in diameter extending for a distance of 2 cm. from the junction with the inclined limbs. The device is useful in analytical operations in which it is desired to keep constant the relative proportions of two interacting solutions.—W. G.

Gas volumes; Chart for the reduction of —. W. Ostwald. Z. angew. Chem., 1919, 32, 359–360.

A GRAPHICAL method for calculating the corrected gas volumes at 0° C. and 760 mm. pressure, with allowance for the vapour tension of water, is illustrated. The chart consists of a logarithmic scale for barometric pressure and a logarithmic scale for the correction factors. By laying a straight-edge between the respective points on these two scales, it is possible to plot a third scale for the corresponding temperatures, which takes the form of a straight line parallel to the other two. The temperature scale thus empirically determined includes the necessary correction for the tension of aqueous vapour. By another series of logarithmic scales the multiplication of the observed volume by the correction factor to give the corrected volume may be provided for on the same diagram, so that it is only necessary to shift the straight-edge from the point of the correction-factor scale, obtained by joining up the barometer and temperature values, across to the point on the observed volume scale in order to read off directly the corrected volume.—J. F. B.

Viscosity of organic colloids; Technique of the estimation of the —. E. Rothlin. Biochem. Zeits., 1919, 98, 34–92.

THE superiority of the "capillary" methods over the "damping" methods in the estimation of the

viscosity of fluids is discussed. The viscosity of various emulsoids under different pressures were determined by means of Hesse's viscometer (capillary principle). Emulsoids like gum arabic, soluble starch, β -gelatin, and casein have been found to obey Poiseuille's law. Others, like gelatin, egg albumin, insoluble starch, agar, and soap, have shown a deviation from this law as the pressure was diminished. The importance of the pressure factor and the dimensions of the capillaries in the determination of the viscosity of fluids is pointed out. Hesse's viscometer fulfils requirements in these respects.—S. S. Z.

Phosphoric acid; Grete's volumetric method [for the determination of] —. R. W. Tuinzing. Landw. Versuchs-Stat., 1919, 94, 191—195.

This method, in which the phosphoric acid is titrated with ammonium molybdate solution containing gelatin (this J., 1888, 771), was found to be trustworthy. Directions are given for the recovery of the ammonium molybdate from the collected titration solutions.—W. P. S.

Ferrous sulphide as an indicator in acidimetry, and a new volumetric method for the estimation of zinc. J. Houben. Ber., 1919, 52, 1613—1621.

MINERAL acids can be titrated with precision by adding a crystal or two of ferrous ammonium sulphate to the solution, passing in a little well-washed hydrogen sulphide, and running in alkali until the mixture just begins to darken. The end-point is somewhat indistinct in the titration of sulphuric acid by borax, but in this case it is possible to titrate back until the dark colour disappears. Zinc is completely precipitated by hydrogen sulphide from zinc sulphate if the solution is less than 0.2N, and from the chloride if the concentration is below 0.067N. Titration of the acid set free would be a means of estimating zinc, and for this purpose the above method is useful. The solution is saturated with hydrogen sulphide, a crystal of ferrous ammonium sulphate is added, and alkali is run in until the white turbidity becomes brownish. Examples of the application of the method to metallic zinc, zinc salts, zinc ash, and blends show that the process is superior to any other volumetric method, the results agreeing very well with those of gravimetric analyses. Of course, metals of group II. are first removed, and cobalt and nickel must be absent. (Compare J. Chem. Soc., 1920, ii., 53.)—J. C. W.

Iron; Volumetric estimation of —. J. Houben. Ber., 1919, 52, 2072—2076. (See preceding abstract.)

The method permits the estimation of ferrous and ferric iron and free mineral acid in a solution. A portion of the solution is completely reduced by hydrogen sulphide and titrated with N/1 alkali hydroxide solution until the dark coloration due to the incipient precipitation of ferrous sulphide is observed and does not disappear after vigorous shaking; the free acid plus one-third of the acid originally combined in the ferric salt is thereby estimated. A second portion of the solution is reduced by sulphur dioxide with complete exclusion of air; most of the excess of the reducing agent is expelled by boiling the solution, and the latter is titrated with N/1 alkali as before, after being cooled and treated with hydrogen sulphide, which completes the removal of sulphur dioxide and also serves as indicator. The free acid, plus two-thirds of the acid originally combined with the ferric iron is thus estimated. The difference between the two titrations multiplied by three gives the number of c.c. of N/1 ferric chloride solution originally

present. If this number is subtracted from the smaller of the two burette readings, the difference is the number of c.c. of N/1 acid which was uncombined in the solution. The ferrous iron is estimated in the usual manner. Test analyses show the method to have a high degree of accuracy.

—H. W.

Arsenic group; Separations in the —. W. Strecker and A. Riedemann. Ber., 1919, 52, 1935—1947.

THE following modification of the distillation method for the estimation of arsenic is recommended. The arsenic solution is placed in a flask provided with a dropping funnel and connected through an efficient worm-condenser to a vessel containing water; the flask is half filled with concentrated hydrochloric acid and potassium bromide (1.5 grms.) and a few pieces of porous pot are added. The contents of the flask are heated to gentle boiling, and 10 c.c. of thionyl chloride is gradually run in during the course of half an hour. The distillate is diluted with water to 700—800 c.c., boiled under a reflux condenser in a brisk current of carbon dioxide until sulphur dioxide is expelled and the sulphur has collected (this should be the case in half an hour at most), and filtered. Arsenic is estimated in the filtrate as the trisulphide. Phosphorus trichloride (25 c.c.) may replace the thionyl chloride, in which case the subsequent boiling of the filtrate is unnecessary, but, on the other hand, the presence of phosphorous acid in the residue often causes complications in subsequent estimations. The method gives accurate results and can be applied to the separation of arsenic from antimony, tin, copper, lead, mercury, and iron, and for the estimation of arsenic and iron in iron arsenide. The separation of antimony from tin can be effected by taking advantage of the fact that antimony chloride is volatile at 155°—165° C. from solutions in which the tin can be retained by the presence of phosphoric acid; the tin can be volatilised subsequently at a somewhat higher temperature if the restraining influence of the phosphoric acid is destroyed by the addition of hydrobromic acid. The authors have attempted to shorten the time required for this separation by utilising the catalysing action of hydrobromic acid from the commencement, but the results are unsatisfactory since tin distils with the antimony, the catalysing influence of hydrogen bromide outbalancing the restraining effect of phosphoric acid. On the other hand, the use of hydrobromic acid is very advantageous in the separation of antimony or tin alone from other elements and does not require the absence of nitric acid. Thus, in the separation of antimony from copper, the solution of the metals in hydrochloric acid is added to concentrated sulphuric acid (6 c.c.) and phosphoric acid (sp. gr. 1.78, 7 c.c.) contained in a distillation flask connected to a receiver containing concentrated hydrochloric acid; the contents of the flask are heated to 160° C., and a mixture of concentrated hydrochloric acid (10 vols.) and hydrobromic acid (sp. gr. 1.78, 1 vol.) is added at such a rate that the temperature remains constant. The antimony is completely removed in 30 mins. The separation of antimony from lead is similarly accomplished. Tin is quantitatively separated from copper and lead in an analogous manner; the solution of the metals in concentrated hydrochloric acid is treated with sulphuric acid (12 c.c.) and distilled at 160° C. with the regulated addition of the hydrochloric-hydrobromic acid mixture (20 c.c.). The process is complete in half an hour; the tin is precipitated from the distillate as the sulphide and weighed as oxide. The method can be applied to the estimation of tin in brass. The separation of antimony and tin from mercury cannot be effected in this

manner, since the latter is also partly volatilised. A novel type of filter tube is described, which is constructed by drawing out the end of a piece of wide glass tubing so as to form a stem; a filter disc covered with asbestos rests on the shoulder of the wider tube, which is further provided with a ground-in cap in which a capillary opening is made.

—H. W.

Molybdenum; Detection of — by means of xanthic acid. J. Koppel. Chem.-Zeit., 1919, 43, 777—778.

THE characteristic reaction between molybdenum compounds and xanthates, first described by Siewert (Z. ges. Naturw., 1864, 23, 5; see Malowan, this J., 1920, 27 A) is capable of detecting 0.00064 mgrm. of molybdenum in l.e.c. when applied in the following manner:—The cold, practically neutral, solution is mixed with a few particles of potassium xanthate and a few drops of a strong acid added. The yellow coloration due to the xanthic acid changes to red, and then to plum colour, in the presence of sufficient molybdenum. If a large amount of molybdenum is present black oily drops separate and adhere to the sides of the flask. The reaction product is stable for hours, but is rapidly destroyed by heat. A somewhat weaker reaction is produced when phosphoric, formic, or acetic acid is used for the acidification, whilst with salicylic acid it is very faint. With oxalic, citric, or tartaric acid little, if any, coloration is produced. The colouring matter may be readily extracted with an organic solvent, preferably chloroform, and the sensitiveness of the reaction thus increased. The compounds formed by metals such as copper, cobalt, nickel, and iron, do not interfere with the test for molybdenum, but vanadates, uranates, and tungstates may possibly interfere. Uric acid gives a pale yellow coloration and vanadic acid a brownish coloration, the coloured compounds in each case being soluble in ether, but the colour is not deep enough to mask the molybdenum reaction. Tungstic acid does give any definite coloration with xanthic acid, and does not interfere with the molybdenum test unless it is present in a very large preponderance, which, however, is frequently the case in technical work. In such cases the solution may be diluted so that the tungstic acid is not immediately precipitated on adding a slight amount of acid, or the tungstic acid may be precipitated by boiling the solution with acid, and the filtrate used for the xanthic acid test. An addition of sufficient phosphate or tartrate to keep the tungsten in solution before acidification will obviate the difficulty caused by the precipitation of the tungstic acid. (See also J. Chem. Soc., 1920, ii., 58.)—C. A. M.

Metals; Electrolytic determination of — without the use of an external current. M. François. Ann. Chim., 1919, 12, 178—192.

A MORE detailed account of work already published (see this J., 1918, 784 A).—W. G.

Inks; Use of commercial — in plant histology. P. Bugnon. Comptes rend., 1919, 169, 1051—1051.

TWO staining mixtures recommended for plant histological work are prepared by adding to a saturated solution of Soudan III. and Light-Green in 70% alcohol one-tenth of its volume of ink and by adding to 100 c.c. of a saturated solution of Soudan III. in 90% alcohol 0.5 gm. of Iodine Green and 5 c.c. of ink. With such mixtures a triple coloration is obtained, the pectocellulose membranes being stained violet by the ink, the cutinised and suberised membranes orange-red by the Soudan III., and the lignified membranes stained

green by either of the greens. The ink used is a commercial iron-tannin or iron-logwood black ink.

PATENTS.

Pyrometric method and apparatus. E. F. Northrup, Princeton, Assignor to Pyroelectric Instrument Co., Trenton, N.J. U.S. Pat. 1,323,309, 2.12.19. Appl., 28.2.19.

IN a pyrometric apparatus, one end of a rod of "light-transmitting material" is subjected to the temperature to be measured, and the other end extends through a tube into, and is observable in, a light-excluding chamber. The temperature of the heated end is determined from the intensity of the light transmitted through the rod.—W. E. F. P.

Thermo-couple; Base-metal —. W. C. Heraeus G.m.b.H., Hanau. Ger. Pat. 302,452, 8.5.17.

A THERMO-COUPLE has its two arms constructed of alloys of nickel with 2—6% and 5—12% of chromium respectively. If alloys of nickel with 3.19% and 7.41% of chromium are employed, using the purest metals obtainable, the indications of the instrument diverge by a maximum of -15° from those of the Pt—Pt Rh couple between 0° and 900° C., and of $+15^{\circ}$ between 950° and 1150° C., while at 950° C. the two couples agree exactly.—L. A. C.

Gas and vapour mixtures; Determination of ingredients which react exothermally in — [e.g., oxygen in hydrogen]. Badische Anilin und Soda Fabrik, Ludwigshafen. Ger. Pat. 303,986, 24.3.17.

THE gas current is divided and passes through two equally heated tubes containing similar thermo-elements which are capable of acting as catalysts for the ingredients of the gas mixture. The thermo-element in one tube is exposed to the gas current, whilst that in the other tube is protected by quartz or other suitable material. The rise in temperature of the exposed thermo-element is measured electrically. The apparatus is suitable for the estimation of traces of oxygen in electrolytically prepared hydrogen.—T. St.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Bennett. Apparatus for diffusing fluids for evaporating, cooling, mixing, etc. 715. Jan. 9.
 Blagden and others. 32,567. *See* XII.
 Bowden and McNaught. Means for raising liquids or mixtures of liquids and solids. 856. Jan. 10.
 Breakell. Grinding and crushing mills. 32,628. Dec. 30.
 Brinjes and Goodwin, and Seaman. Roller grinding mills. 32,121. Dec. 22.
 Brown and Urquhart. Centrifugal filters, strainers, separators, etc. 551. Jan. 7.
 Bucci. Cooking-ovens or drying apparatus. 27. Jan. 2.
 Buckley. 32,332. *See* XIX.
 Butters and Co., and Memmell. Apparatus for indicating density of liquids and automatically grading same accordingly. 32,416. Dec. 24.
 Candlot. Furnaces, ovens, etc. 32,573. Dec. 29. (Fr., 10.7.17.)
 Delaygue. Solution for use with apparatus for refrigerating by liquefaction. 367. Jan. 5.
 Diver. Process of ground distillation. 32,165. Dec. 23.
 Ellis. Distillation apparatus. 698. Jan. 8.
 Frazer and Sealione. Catalysts, and processes of making them. 575. Jan. 7.
 Henning. Solvents for extraction purposes. 32,433. Dec. 24.
 Imray (Ruggles-Coles Engineering Co.). Drier. 32,852. Dec. 31.
 Jones and McKean. Liquid-fuel furnaces. 32,461. Dec. 29.
 Kirk. Heat-treating furnace. 32,429. Dec. 24.
 Lovelace, Miller, and Patrick. Separating gases. 32,408. Dec. 24. (U.S., 28.12.18.)
 Manlove, Allott and Co., and Mason. Oil-fired furnaces. 711. Jan. 8.
 Mitchell. Apparatus for transferring material and for separating mixtures etc. 594. Jan. 7.
 Paget. Grinding, refining, or reducing apparatus. 169. Jan. 2.
 Pirrie. 74. *See* V.
 Raworth (Soc. Anon. des Appareils de Manutention et Fours Stein). Oil-burning furnaces. 32,796. Dec. 31.
 Rosanoff Process Co. Fractionating apparatus. 32,582. Dec. 29. (U.S., 23.12.18.)
 Soc. Anon. d'Exploit de Proc. Evaporatoires Système Prache et Bouillon. Evaporating apparatus. 32,140. Dec. 22. (Fr., 24.12.18.)
 Thoens. Refrigerating. 32,291. Dec. 21.
 Wilton. Centrifugal machines. 905. Jan. 10.
 Wright. Means for supplying liquid, powdered, etc. substances to furnaces etc. Jan. 2.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8529 (1918). Gallot et Cie. *See* XI.
 14,617 (1918). Ely. Lining of furnaces. (136,860.) Jan. 7.
 16,758 (1918). Steiger and Steiger. Gas-fired shaft kilns for burning and roasting non-sintering substances. (136,588.) Dec. 31.

- 21,060 (1918). Harris. Drying-apparatus. (136,631.) Dec. 31.
 21,085 (1918). Odum. Atomising materials in a melted state. (122,103.) Dec. 31.
 21,286 (1918). Shaw. Apparatus for evaporating or concentrating liquids. (136,651.) Dec. 31.
 21,452 (1918). Hughes. Methods and apparatus for carrying out certain chemical reactions. (136,896.) Jan. 7.
 3065 (1919). Taylor. Vacuum drying-ovens. (136,703.) Dec. 31.
 5220 (1919). Chaudière. Shaft-furnaces and gas-producers. (137,168.) Jan. 11.
 12,588 (1919). Coles, and Allen and Co. Apparatus for mixing, circulating, and agitating materials in a liquid or semi-liquid state. (136,758.) Dec. 31.
 14,219 (1919). Corbett. Grinding-mills of the rotating disc type. (137,231.) Jan. 14.
 21,228 (1919). Gerlach. Drums for drying materials. (133,327.) Jan. 7.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- André. Recuperation of combustible material contained in ashes from furnaces etc. 32,709. Dec. 30.
 Barber. Apparatus for drying and filtering illuminating gases. 747. Jan. 9.
 Bateman. Continuous carbonisation of coal etc. by inclined retorts. 32,438. Dec. 29.
 Bates. Fuel. 32,048. Dec. 22. (U.S., 5.8.19.)
 Berg. Distilling and refining volatile substances and carbonising and coking the same. 32,096. Dec. 22. (Fr., 21.12.18.)
 Crowther. Spent-oxide burner. 728. Jan. 9.
 Gardner, and Woodall, Duckham, and Jones. Vertical retorts for carbonising coal. 32,220. Dec. 23.
 Green and Leek. Methods of revivifying material in gas-purifiers. 32,073. Dec. 22.
 McComb. 32,309. *See* III.
 Meade. Distillation of coal etc. 288. Jan. 5.
 Paris. Cleaning and refining distillates of petroleum. 70. Jan. 2.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

- Adam and Legg. Reduction of nitro-compounds. 32,351. Dec. 24.
 Barker. Tar-distilling plant. 32,059. Dec. 22.
 British Dyestuffs Corporation, Green, and Porter. Manufacture of phthalic acid and anhydride. 862. Jan. 10.
 Commin. Treating pitch. 79. Jan. 2.
 McComb. Process of converting liquid hydrocarbons. 32,309. Dec. 24.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATION ACCEPTED.

- 10,797 (1919). Thompson (Poulenc Frères, and Meyer). Manufacture of 3,6-diaminoacridine. (137,214.) Jan. 14.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Brydon, Forster, and Turner. Treatment of paper etc. for electrical, chemical, etc. purposes. 60. Jan. 2.
 Colebrook, Langlois, Moncorget, and Tebbitt. Retting textile plants. 32,473. Dec. 29.
 Distillates, Ltd., and Jarman. Treatment of wool or piece scouring liquors or effluents. 32,486. Dec. 29.
 Great Northern Paper Co. Paper-making machines. 32,349. Dec. 24. (U.S., 31.1.17.)
 Great Northern Paper Co. Making paper. 706. Jan. 8. (U.S., 26.3.18.)
 Howden. Apparatus for drying coated or enamelled paper, waterproofed cloth, etc. 32,787. Dec. 31.
 Langwell and others. 694. *See XVIII.*
 Pirrie. Drying fibrous, granular, pulpy, etc. materials. 74. Jan. 2.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,188 (1917). Korselt. Increasing the strength and elasticity and preventing or decreasing subsequent weakening of the fibres of loaded silk. (136,578.) Dec. 31.
 21,790 (1918). Skinner. Preparation of pulp or fibrous material for making paper, papier-mâché, etc. (137,105.) Jan. 14.
 9576 (1919). De Cew and Marx. Treatment of paper pulp. (137,207.) Jan. 14.
 19,298 (1919). Clayton. Apparatus for making artificial silk. (136,784.) Dec. 31.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

- Baldwin and Partners, and McIntosh. Bleaching wool etc. 645. Jan. 8.

- Burgess, Ledward, and Co., and Harrison. Dyeing artificial silk. 722 and 723. Jan. 9.
 Cole and Kershaw. Machines for dyeing, mordanting, bleaching, scouring, etc. wool, yarn, etc. 32,733. Dec. 31.
 Heap. Rotary perforated beam apparatus for dyeing etc. yarn. 511. Jan. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

- 21,864 (1918). Lord and Lord. Machines for dyeing, washing, scouring, sizing, mercerising, and bleaching yarn in the hank form. (136,666.) Dec. 31.
 4229 (1919). Morley, and Bleachers' Assoc. Machines for bleaching and similarly treating textile fabrics and yarns in rope form. (136,713.) Dec. 31.
 5788 (1919). Driver and Sunderland. Apparatus for testing colour fastness in dyed fabrics. (136,971.) Jan. 7.
 6926 (1919). Samuel. Machines for printing fabrics or the like. (126,948.) Jan. 7.
 9108 (1919). Davis and Davis. Dyeing-machines. (136,991.) Jan. 7.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Ashcroft. Nitrogen fixation and manufacture of nitrogen compounds. 122. Jan. 2.
 Craig. Recovering potash etc. salts from blast-furnace gases. 839. Jan. 10.
 Datta. Manufacture of alkali bichromates and production of sulphates. 309. Jan. 5.
 Douglas. Manufacture of ammonia. 32,756. Dec. 31.
 Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of potassium sulphate. 32,568 and 32,672. Dec. 29 and 30. (Fr., 28 and 30.12.18.)
 Fredriksstad Elektroemiske Fabriker Aktieselskabet. 32,886. *See XI.*
 Fredriksstad Elektrokemiske Fabriker Aktieselskabet. Manufacture of perborates. 489. Jan. 6. (Norway, 4.3.19.)
 Golding, and United Alkali Co. Manufacture of ferrous sulphide and sulphuretted hydrogen. 32,112. Dec. 22.
 Heberlein. Method for electrolysing a solution of nickel salt. 32,853. Dec. 31.
 Jones and Kelly. Preparation of sodium pentaborate etc. direct from boron ores. 648. Jan. 8.
 Kelly. Manufacture of acid sodium pyrophosphate. 353. Jan. 5.
 Loring. Electrodes for oxidising nitrogen. 32,763. Dec. 31.
 Mackay. Obtaining strontium and barium sulphates from their native sulphates or carbonates. 822. Jan. 9.
 Mackay. Obtaining copper sulphate direct from metallic copper. 823. Jan. 9.
 Napp (Tschudi). Manufacture of hydrobromine from hydrogen and bromine. 433. Jan. 6.
 Norsk Hydro-Elektrisk Kvaestofaktieselskab. Production of concentrated nitrous gases. 32,397. Dec. 21. (Norway, 21.10.16.)
 Officine Elettrochimiche Dr. Rossi, and Toniolo. Production of hydrogen and mixtures of hydrogen and nitrogen. 32,414. Dec. 24. (Italy, 21.10.19.)
 Officine Elettrochimiche Dr. Rossi, and Toniolo. Production of hydrogen. 366. Jan. 5. (Italy, 29.10.19.)
 Shah. Manufacture of zinc chloride. 32,717. Dec. 30.
 Sutcliffe. Apparatus for hydrating lime etc. 32,144. Dec. 22.
 Thibault. Conversion of metallic lead into its oxides. 32,539. Dec. 29. (Fr., 30.12.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 4562 (1919). Fairbrother (Chemical Construction Co.). Apparatus for recovering potassium compounds. (136,718.) Dec. 31.
 6928 (1919). Golding, Raschen, and United Alkali Co. Purification of calcium citrate and manufacture of citric acid. (136,979.) Jan. 7.
 10,188 (1919). Jackson (Air Reduction Co.). Manufacture of cyanides. (136,750.) Dec. 31.
 14,439 (1919). Hedstrom. Production of compounds of radium. (136,768.) Dec. 31.
 15,560 (1919). Thorssell and Lundén. Production of cyanides. (136,772.) Dec. 31.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

- British Thomson-Houston Co. (General Electric Co.). Substances for coating glass surfaces. 674. Jan. 8.
 Kent. Manufacture of glass tubing having more than one bore. 50. Jan. 2.
 Kent. Manufacture of thermometer tubing. 51. Jan. 2.

IX.—BUILDING MATERIALS.

APPLICATIONS.

- Knapp and Slade. Fuming oak etc. 185. Jan. 2.
 Smidth & Co. Building material for concrete structures. 189. Jan. 2. (Denmark, 1.5.18.)
 Smidth & Co. Method of making concrete. 641. Jan. 8. (Denmark, 8.1.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 4771 (1918). Jones (White Heat Products Co.). Manufacture of artificial stones. (136,580.) Dec. 31.
 185 (1919). Gladman. Manufacture of wood substitutes. (137,115.) Jan. 14.
 5358 (1919). Frydenland. Production of porous building and insulating bodies. (123,992.) Jan. 7.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Brettschneider and Schäfer. Case-hardening mixtures for iron and steel. 32,093. Dec. 22.
 Craig. 839. *See* VII.
 Edser and others. 32,376. *See* XII.
 Johanson and Stönen. Treating weakly magnetic iron ore containing sulphides as secondary constituents. 32,571. Dec. 29.
 Kirk. 32,429. *See* I.
 Loring. Method of altering electrical conductivity of metals. 32,764. Dec. 31.
 Mackay. Obtaining iron and tin from tin scrap. 821. Jan. 9.
 Metallindustrie Schiele und Bruchsalder. Production of aluminium castings. 65. Jan. 2. (Ger., 18.2.18.)
 Quinoneri. Magnetic separators for treating ferrous ores. 32,409. Dec. 24.
 Ramen. Roasting sulphur ores containing low percentage of sulphur. 589. Jan. 7.
 Ramen. Roasting furnaces. 691. Jan. 8.
 Redfern (Guthridge, Ltd.). Ore-concentrating tables. 32,133. Dec. 22.

Contact catalysis; Further problems in —. H. S. Taylor. Trans. Amer. Electrochem. Soc., 1919, 167—173. [Advance proof.]

SEVERAL features of the phenomenon of contact catalysis in cases where carrier action or formation of intermediate compounds does not take place, are discussed by the author. Most contact agents have a porous or finely divided structure, e.g., bog iron ore, firebrick, platinum deposited on asbestos, etc., and platinum gauze, which acquires activity in use, is found to have developed a corrugated, pitted surface. Although these porous materials are also adsorbent, yet the two phenomena of catalysis and adsorption are quite distinct. Thus, although charcoal shows marked adsorptive action towards carbon monoxide, oxygen, and carbon dioxide, its activity in promoting the oxidation process is practically nil compared with metallic oxides. On the other hand, ethylene and oxygen react at ordinary temperatures in presence of charcoal. The differentiations may be due to the relative adsorptive capacities of charcoal and metallic oxides in one case, and preferential adsorption of particular gases by charcoal in the other. Data in regard to the amounts of gases which may be adsorbed separately or from a mixture are still scanty. The effect of poisons on catalytic agents may be explained by their interference with the adsorptive properties of the catalyst, but the time factor or velocity of adsorption must be taken into consideration, and since the normal time of contact is extremely short, the effect of the poison may be due to a reduction of the velocity with which adsorption occurs. Charcoal used for gas masks gave very different results in the "clean" and "unclean" condition. The adsorption curves indicate that although the ultimate amount adsorbed would be the same, yet the clean charcoal has a much higher velocity of adsorption in the early stages. The nature of the adsorbent is important, and an alteration of its chemical reactivity influences its catalytic activity. Copper oxide wire is reduced by hydrogen at 300° C., but if the copper is oxidised at a lower temperature, subsequent reduction will occur at a temperature as low as 100° C., and such copper oxide will also catalyse hydrogen and oxygen at 100° C. The increase of catalysis by promoters, such as small quantities of chromium oxide added to iron oxide, has not been fully accounted for.—W. J. W.

Heterogeneous catalysis; Reactivity and adsorption in —. E. K. Rideal. Trans. Amer. Electrochem. Soc., 1919, 203—211. [Advance proof.]

THE mechanism of heterogeneous catalysis involves investigations as to the way in which the medium in juxtaposition to the catalyst differs from that in the free space and of the effect on reaction velocity caused by alteration in the state of the medium. Adsorption is now regarded as the primary action in catalysis, and surface adsorption is frequently accompanied by intra-solid diffusion, resulting in formation of solid solutions within the body of the solid material, but since catalytic action is proportional to the area of the catalytic material, intra-diffusion plays a small part. Divergent opinions prevail in regard to the surface film in which catalytic reactions take place. Three theories have been expounded to explain why quasi-chemical combination between reacting substances and catalytic material accelerates a reaction which proceeds but slowly when chemical combination alone occurs. Fink and Bodenstein assume that every molecule penetrating the diffusion layer to the catalyst surface reacts, the rate of catalysis being governed by

the rate of diffusion of the reacting substances or of the products. According to the single layer theory, only those molecules of the reacting substances undergo chemical combination which strike the catalyst in juxtaposition to one another, the rate of catalysis being usually governed by the rate of evaporation of the products from the surface. The hypothesis of the critical energy increment assumes that molecules in juxtaposition only react when they attain a certain critical energy.

—W. J. W.

Steam; Effect of the oil present in exhaust — upon the efficiency of evaporators in sugar factories. H. Claassen. Z. Ver. deut. Zuckerind., 1919, 128—135.

EXAMINATION of the vapour space of an evaporator heated by exhaust steam, which after leaving the engines had been passed through an oil separator, showed that at the end of the season only those tubes immediately opposite and contiguous to the steam inlet had become contaminated with oil, and that the average thickness of the layer did not exceed 0.005 mm. Owing to the small proportion of the total heating surface of the evaporator thus affected, the efficiency of the apparatus had not been diminished appreciably under the conditions obtaining in the test.

—J. P. O.

Colours; Heat-reflecting properties of — applied to oil and gas storage tanks. H. A. Gardner. Paint Manufacturers' Assoc., U.S.A., Circ. No. 44. Jan., 1917. 2 pages.

THE effect produced by the calorific rays on surfaces painted in various colours was determined with a view to application of the results to storage tanks containing volatile distillates. Determination of the rise in temperature of the contents of small cylindrical metal tanks containing benzine (petroleum spirit), the exterior surfaces of which were painted in various colours, were made after 15 minutes' subjection to the rays of a powerful arc. Gloss paints were selected on account of their lesser absorption of thermal rays than those presenting a matt surface. A container of tin plate (unpainted) and one painted with aluminium paint gave the lowest recorded rises in temperature, i.e., 19.8° F. and 20.5° F. (11° C. and 11.4° C.) respectively, but white and light-coloured paints giving rises of 22.5° F. and 23°—26.6° F. (12.5° C. and 12.8°—14.8° C.) are to be preferred from the point of view of their serviceability and the protection they afford. With a black paint a rise of 51° F. (30° C.) was recorded, whilst red oxide paint showed a rise of 29.7° F. (16.5° C.).—A. de W.

Thermo-couple installation. Williamson and Roberts. See VIII.

PATENTS.

Refrigerating apparatus. Apeldoornsche Machinefabriek en Metaalgieterij voorheen Loog Landaal, Apeldoorn, Netherlands. Eng. Pat. 125,358, 21.11.18. (Appl. 19,106/18.) Int. Conv., 8.4.18. Addition to 120,923 (this J., 1920, 51 A).

THE compression cylinder is surrounded by a jacket from which the high-pressure vapour enters the cylinder through a ring of small openings formed so that their cross-section grows wider in the direction of the jacket, and which are unclosed by the piston at the end of the suction stroke. The high-pressure vapours enter the jacket from a main through an opening whose cross-section also grows wider in the direction of the jacket. The intermediate receivers and the liquid separator are provided with inlet and outlet openings of a similar conical form.—W. H. C.

Refrigerating apparatus. G. A. Wegner, Rochester, N.Y., Assignor to Wegner Machine Co., Buffalo, N.Y. U.S. Pat. 1,325,128, 16.12.19. Appl. 13.5.18.

In a refrigerator employing a volatile liquid, the supply of liquid is maintained at a predetermined pressure, and the discharge of vapour is controlled by a valve governed by the temperature of the issuing gas, a temperature above the saturation point being used.—B. M. V.

Distillation; Apparatus for fractional —. E. A. R. Chenard, Cognac, France. Eng. Pat. 130,992, 5.8.18. (Appl. 19,318/19.) Int. Conv., 5.8.18.

The vapours from the still pass first through a series of concentric pipes, where heat interchange takes place between the ascending vapours and the returning condensed liquid. The vapours next pass through a bent pipe into a series of doubly conical vessels, each provided near the outlet end with a scrubber or filter-box charged with finely-divided material to help the separation of the condensed liquid, which is returned to the bent pipe by tubes provided with siphons and taps to enable part of the liquid to be withdrawn. The vapour passes from the last of the conical vessels to an ordinary condenser.—W. H. C.

Air filters; Bag cleaning devices for —. W. F. L. Beth, Lübeck, Germany. Eng. Pat. 132,513, 9.9.19. (Appl. 22,128/19.) Int. Conv., 9.9.18.

TUBULAR filter bags used for filtering air are cleaned by repeatedly slackening and tightening them, the bags being held taut during the filtering period. A device consisting of levers and two cams effects this: one slowly rotating cam determines the periods of cleaning and stationary filtering, and the other cam, rotating faster, provides the slackening and tightening effect.—B. M. V.

Raising liquids by direct fluid pressure; Apparatus for —. J. E. L. Ogden, Liscard. Eng. Pat. 135,900, 26.11.18. (Appl. 19,416/18.)

THE liquid to be raised flows into the vessel, 2, from a tank placed at a higher level, passes through the pipe, 4, lifts the valve, 8, off its seat, 9, and fills

the vessel, 2, driving out the air through the opening, 19, into the rising main, 12. When the liquid rises to the level of the opening, 11, in the chamber, 5, it flows through and traps the air in 5, and at the same time compresses it slightly. This causes the dead weight, 14, fastened at the upper end to the diaphragm, 15, which closes the box, 6, to lift

until the projection, 16, comes into contact with the stud, 17. The air-inlet valve, 7, lifts slightly and compressed air enters by the pipe, 13, and the pressure beneath the weight increases until it overcomes the resistance of the lever and weight, 18, when the valve, 7, opens wide and allows the compressed air to enter freely. The pressure of the air forces down the valve, 8, on to its seat and drives the liquid up the rising main, 12. The air vent, 19, is provided with a projection, 21, against which the liquid impinges, and this helps to seal the opening, 19, until all the liquid is forced out of the vessel, 2; when this has taken place the air escapes up the rising main, the pressure in the vessel falls, the valve, 7, closes and 8 is opened, and the operation recommences.—W. H. C.

Grinders; Impact —. W. S. and G. S. Barron, Gloucester. Eng. Pat. 135,955, 6.12.18. (Appl. 20,253/18.)

THE grinding chamber is divided into two compartments by a rotating disc which carries impact studs on both sides. The material is fed into the first compartment, where it receives a preliminary grinding and then passes through a passage to the second compartment on the other side of the disc where it receives a final grinding, the finely-ground material being discharged through a peripheral screen. Any particles too coarse to pass through the screen are returned by way of the conduit between the compartments to the grinding portion of the second compartment, and are not ground against the screen, so that the life of the latter is prolonged.—W. H. C.

Filter-presses. R. W. Webster, London. Eng. Pat. 135,976, 17.12.18. (Appl. 21,057/18.)

In filter-presses of the type in which the liquid to be filtered passes through layers of filtering material, supported by a series of frames, connected with common inlet and discharge pipes, one or more preliminary filter surfaces are provided through which the liquid is passed first so that it may receive a preliminary filtration before it reaches the main filter surface. At first the liquid is fed through the preliminary filters to the main filter, but when these become clogged the flow is diverted by means of suitable valves directly to the main surface. In this way the frequency with which the press has to be cleaned is lessened.—W. H. C.

Liquids; Apparatus for separating solid particles of matter from —. W. Acton, Paisley. Eng. Pat. 135,992, 30.12.18. (Appl. 21,756/18.)

AN endless band of filter cloth is arranged to pass round a drum, which has its surface divided by transverse partitions into separate suction chambers each connected separately to the hollow shaft, then over a breaking roller to discharge the deposit, and back to the drum, against the surface of which it is pressed by a spring guide roller. The drum is rotated, partly immersed, in a tank which contains the liquid to be filtered, and the hollow shaft is connected to a vacuum pump, and is also provided with a valve by which the suction is cut off from that suction chamber the surface of which is exposed whilst the cloth is passing over the breaking roller. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 19,600 of 1890, 2257 of 1891, 1591 of 1892, 9956 and 22,871 of 1898, 19,237 and 22,852 of 1901, 10,071 of 1904 and 120,055; this J., 1899, 120, 498; 1901, 1194; 1902, 243; 1919, 24 A.)—W. H. C.

Gas furnaces. South Metropolitan Gas Co., and D. Chandler, London. Eng. Pat. 136,356, 28.1.19. (Appl. 2097/19.)

In gas furnaces of the type in which the flame

passes tangentially into the furnace, part of the air for combustion is admitted tangentially to the wall of the furnace at about the point where the flame would otherwise impinge, with the result that noise and local overheating are reduced.—B. M. V.

Dehydrating apparatus. C. Shorman, Chicago, Ill. U.S. Pat. 1,324,073, 9.12.19. Appl., 18.6.15.

THE material to be dried is supported on trays in a vertical cylindrical chamber, and air is supplied to a central hollow shaft provided with discharge pipes, in the form of arms which rotate in proximity to the material.—B. M. V.

Heating drum. H. C. Janes, Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,324,157, 9.12.19. Appl., 12.11.17.

A HORIZONTAL rotary cylinder is provided with an annular jacket, and is supported by coaxial horizontal hollow trunnions projecting outwards and carried by bearings. Fluid is supplied to the interior of the cylinder through one of the trunnions and exhausted through the other. The annular jacket is connected by radial pipes at each end with concentric hollow sleeves surrounding the trunnions and supported by independent bearings. Fluid is supplied to and exhausted from the jacket through the hollow sleeves.—W. F. F.

Reactions between gases; Apparatus for bringing about and controlling —. C. Conover, Philadelphia, Pa. U.S. Pat. 1,324,443, 9.12.19. Appl., 30.4.19.

THE gases pass from a supply chamber to a number of reaction chambers, being equally distributed among the latter by suitably restricted passages. The temperature of reaction is controlled by the circulation and boiling of a liquid in jackets surrounding the reaction chambers.—B. M. V.

Centrifugal extractor. F. M. Watkins, Cincinnati, Ohio. U.S. Pat. 1,325,064, 16.12.19. Appl., 9.8.16. Renewed 26.10.17.

THE side wall of the centrifugal basket is inclined upwards and outwards, so that material within the basket tends to be discharged outwards over the rim during rotation. Means are provided for preventing such discharge of solids while permitting discharge of liquid, such means having radial partitions projecting inwards into the basket and rotating with it. The solids may be discharged by an axial movement of the restraining means.—W. F. F.

Precipitating matter from gases; [Electrical] process and apparatus for —. W. W. Strong, Mechanicsburg, Pa. U.S. Pat. 1,325,124, 16.12.19. Appl., 23.10.18.

THE apparatus comprises an active electrode in contact with the gas and having a relatively great surface curvature, with a passive electrode out of contact with the gas and having a comparatively small surface curvature.—B. N.

Electrical treatment of gas; Apparatus for —. L. Bradley, East Orange, N.J., Assignor to Research Corporation, New York. U.S. Pat. 1,325,136, 16.12.19. Appl., 18.2.16.

AN apparatus for the electrical treatment of gases is provided with a number of flues of polygonal cross-section having walls forming an electrode, and with discharge electrodes extending longitudinally through the flues.—B. N.

Measuring quantities of different materials in varying proportions; Apparatus for —. T. Lea, Wolverhampton. Eng. Pat. 135,888, 16.4.19. (Appl. 16,854/18.)

Electro-osmotically removing water; Apparatus for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Eng. Pat. 135,820, 25.6.18. (Appl. 10,459/18.) Int. Conv., 20.10.17.

SEE Ger. Pat. 311,663 of 1917; this J., 1919, 544 A.

Heat-changes; Method and apparatus for inducing —. R. Vuilleumier, New Rochelle, N.Y., U.S.A. Eng. Pat. 136,195, 4.6.18. (Appl. 9215/18.)

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Extraction of — under pressure with solvents other than benzene. F. Fischer. Ges. Abhandl. zur Kennt. der Kohle, 1919, 3, 246—247. Chem. Zentr., 1919, 90, IV., 632.

THE oil soluble in light petroleum spirit which was previously obtained by extracting coal under pressure with benzene may also be obtained by extracting soft coal directly with petroleum spirit (b. pt. 60°—100° C.) under pressure at 250° C. The quantity of the yellowish-red, viscous product, which apparently contains paraffin scale, amounts to 1% of the coal. Extraction in a similar manner with ethyl acetate yields 2% of a yellowish-red, translucent oily resin. Alcohol extracts a thick golden-yellow oil, also some sodium chloride.—J. F. B.

Coal; Manufacture of a dense, semi-coke by the low-temperature carbonisation of —. F. Fischer. Ges. Abhandl. zur Kennt. der Kohle, 1918, 3, 102—104. Chem. Zentr., 1919, 90, IV., 633—634.

IN rotating apparatus the simple insertion of a sufficiently heavy roller when using powdered coal brings about such a considerable compacting of the semi-coke that it may be utilised as a smokeless fuel, and is suitable for transportation. The recovery of low temperature tar and gases is not interfered with by the roller. For example, from 15 kilos. of gas coal there were obtained 11.3 kilos. of compact semi-coke, apparent sp. gr. 0.68, and 1.5 kilos. of tar oils. The arrangement also permits the introduction of steam or the application of vacuum.—J. F. B.

Gas industry; Refractory problems of the —. W. H. Fulweiler and J. H. Taussig. J. Ind. Eng. Chem., 1919, 11, 1153—1157.

BOTH fireclay and silica products are used as refractory materials, and this gives rise to complex problems in the design and construction of the retort benches, on account of the difference in expansion. In the combustion chamber, retorts, and connecting blocks exposed to 1550° C., a high-grade silica material with over 96% of silica and about 1.5% of lime is used. In recuperators, with a temperature range of 850°—1100° C., fireclay material containing 55% of silica is used. At the top and bottom of the retorts fireclay is used on account of its small coefficient of expansion and resistance to spalling. The outer walls are made of a lower-grade firebrick. The whole bench should be insulated with kieselguhr. In water-gas apparatus the effect of high temperatures, abrasion, slagging, and spalling have.

to be considered. In the generator the lining is subjected to abrasion by the fuel particles whirled about by the blast, and by the pokers and other tools. In the combustion zone the lining is subjected to high temperature, slagging action from the fuel-ash, some abrasion by the fuel, and more or less serious abrasion by the clinker. In the lower portion of the generator the lining is subjected to the action of steam, hot gases, and the tools used for removing the clinker. In the connecting ducts there are high temperature, erosion by particles of fuel and slagging action of the ash. In the carburettor the chequer-bricks and crown are subjected to high temperature and sudden cooling, causing spalling. The usual lining for generators is fireclay brick; silica and magnesite bricks are not successful owing to the changes in temperature. Chromite, zirconia, and carborundum bricks seem good, but are about 30 times as costly as fireclay bricks; they reduce the adhesion of slag to the lining, and therefore the amount of cleaning required. For chequer-work flint-clay bricks are best. The cements used should be free from plastic clay or other material added to give smooth working; they should be of ground grog with a minimum quantity of rather more fusible material.—A. B. S.

Carbonising variations effected by temperature changes in the top of the coking chamber. A. H. Middleton. Northern Sect., Coke-Oven Managers' Assoc., Dec., 1919. Gas World, 1920, 72, Coking Sect., 13—17.

AN investigation into the cause of the presence of large quantities of paraffin hydrocarbons in the crude benzol from a set of coke-ovens at Langley Park is described. In the rectified products 8–9% of paraffins was found in the benzol, 2–4.5% in the "pure" toluene, and as much as 26% in the solvent naphtha. In the installation there is an exceptionally great distance between the top of the heating flues of the coke-ovens and the crown of the oven arch, and hence only comparatively low temperatures are obtained at the top of the retort when fully charged. The paraffin content of the crude benzol could be decreased by reducing the coal charge so as not to fill the top of the oven, or by fully charging with fine coal, all of the coal or its distillation products being then subjected to a high temperature. The same result could be obtained by fully charging with large coal, and working with a higher gas pressure in the flue and lengthening the flame. Charging the ovens with fine coal reduced the output of the ovens, but gave an improved coke. The high yield of paraffins corresponded with a decreased yield of benzol and naphthalene, but an increased yield of ammonia. A gas of excellent quality was also obtained.—W. P.

Ethylene present in coke-oven gas; Fixation of — as alcohol and its derivatives. E. Bury. Cleveland Inst. Eng. Gas J., 1919, 148, 718—721.

PEAT coke has been used successfully at the Skinninggrove Ironworks during the war for the separation of ethylene and other gases from the gaseous products of carbonisation processes (this J., 1919, 857 A). Though this method is advantageous in some cases, sulphuric acid (95%) is preferable as an absorbent when liquid derivatives of ethylene are to be prepared. The hot gas from the retorts is cooled and purified in the usual manner, and then passed through a drying scrubber in which 80% sulphuric acid is circulated. The gas is then heated to 60°–80° C., the hot retort gases being utilised for this purpose, and is then passed into the ethylene scrubbers, which contain 95% sulphuric acid also maintained at 60°–80° C. The acid flows in the opposite direction to the gas, the acidity being reduced by about 10% on leaving the scrubbers. The alcohol is distilled off by means of superheated steam, or acetic acid may be obtained by electro-

lysis or by the use of ozonised air. Any sulphur dioxide formed by the reduction of the sulphuric acid is recovered by interaction with hydrogen sulphide in the crude coke-oven gas. A plant dealing with 5800 tons of coal per week should yield 9280 galls. of absolute alcohol, taking a 50% conversion of ethylene to alcohol as actually obtained. The reduction in calorific value of the extracted gas is small.—W. P.

Carbon, hydrogen, and methane; Equilibrium between —. H. F. Coward and S. P. Wilson. Chem. Soc. Trans., 1919, 115, 1380—1387.

THE proportion of methane in equilibrium with carbon and hydrogen diminishes with increasing temperature, and hence when equilibrium is once established in the zone of reaction the cooling of the gaseous mixture on its removal from the carbon is not accompanied by an alteration in composition. The series of experiments described were carried out in the same manner as those of Bone and Coward (this J., 1908, 1143; 1910, 744) except that the gaseous products of reaction were passed backwards and forwards over the carbon used until analysis showed the attainment of constancy of composition. The percentage compositions of the equilibrium mixtures of methane and hydrogen in contact with amorphous carbon at atmospheric pressure were found to be: at 1100° C., CH₄ 0.6, H₂ 99.4%; at 1000° C., CH₄ 1.1, H₂ 98.9%; at 850° C., CH₄ 2.5, H₂ 97.5%. The attainment of equilibrium was found to be extremely slow with highly-purified charcoal (ash 0.06%) at temperatures below 1100° C.; a series of experiments was therefore carried out using a mixture of equal weights of the charcoal and nickel oxide. Experiments at 650° C. indicated that equilibrium could not be attained within any reasonable period of time. Carbon monoxide was found to be present in the equilibrium gas mixtures; its formation was due partly to a slight oxidising action by the glaze of the heated tube, but mainly to a side reaction between carbon and water vapour.—W. P.

Flame; Propagation of — in complex gaseous mixtures. Part I. Limit mixtures and the uniform movement of flame in such mixtures. W. Payman. Chem. Soc. Trans., 1919, 115, 1436—1445.

FROM a consideration of the heat balance existing during the propagation of flame in limit mixtures a "limits generalisation" is advanced, from which simple formulæ are deduced which enable the limits of inflammability of complex gaseous mixtures to be calculated from the known values for its simple constituents. The generalisation states that all mixtures, in any proportions, of limit mixtures of the same kind are themselves limit mixtures, the limiting percentage being that of the mixed inflammable gas. The expression deduced from this for air mixtures is the same as the empirical formula advanced by Le Chatelier, which has been experimentally verified (this J., 1919, 126 A). Where the combustible gas remains the same and the atmosphere of oxygen and nitrogen varies in composition, the percentage of combustible gas will be directly proportional to the oxygen present in the different limit mixtures. This is shown to be true over a wide range of upper and lower limits of inflammability of methane in different atmospheres, a slight deviation being noted in mixtures containing a large excess of nitrogen. The experiments described in this and the following papers were carried out in a glass tube 2.5 cm. in diameter. The limits of inflammability of methane in pure oxygen were found to be 5.7% and 59.2%. Carbon was deposited by the flames in all upper limit mixtures containing more than 38% CH₄. The speed of the uniform movement of flame was approximately

constant in all the limit mixtures, and was the same as the limiting speed in limit mixtures of air with the paraffin hydrocarbons, namely, 20 cm. per sec. in the tube used. The limits of inflammability of the paraffin hydrocarbons in air were: methane 5.8% and 13.3%, ethane 3.3% and 10.6%, propane 2.4% and 7.3%, butane 1.9% and 6.5%, and pentane 1.6% and 5.4%. Convection currents have a marked effect upon the limits, and must be taken into account in any attempt to calculate the limits of inflammability of a gas from its thermal constants.

—W. P.

Flame; Propagation of — in complex gaseous mixtures. Part II. The uniform movement of flame in mixtures of air with the paraffin hydrocarbons. W. Payman, Chem. Soc. Trans., 1919, 115, 1446—1453. (See preceding abstract.)

SINCE the speed of the uniform movement of flame is approximately the same in all limit mixtures in a given tube, then all mixtures of gas mixtures having this limiting speed will show the same speed of propagation of flame. This is shown to apply to other speeds besides those in limit mixtures. A "speed generalisation," namely, that all combinations of mixtures in which the speed of the uniform movement is the same will propagate flame at the same speed, is shown to hold accurately for different mixtures of air with methane and pentane respectively. The generalisation affords a means of calculating the speed of the uniform movement in any complex inflammable gas mixture, provided the maximum speed of flame is the same for each combustible gas. Where they are not the same the calculation is limited by the maximum speed of flame which is lowest. In this case the maximum-speed mixture (with air mixtures) can be calculated by the method given in an earlier paper (this J., 1919, 126 A), and its speed by means of the following expression:—

$$S = \frac{aS_s + bS_b + cS_c + \dots}{a + b + c + \dots}$$

where S is the speed required, a, b, c, \dots are the amounts present of each maximum-speed mixture with air as calculated, S_a, S_b, S_c, \dots are the speeds of flame in those mixtures respectively. The maximum speed of flame for mixtures of any complex combustible gas with air can also be found by a simple graphical method. The curves obtained by such calculations are shown to agree closely with those obtained from experimental determinations of the speeds in mixtures of pentane and methane and of pentane and hydrogen. The speeds of the uniform movement of flame in a 2.5 cm. tube were determined for each of the paraffin hydrocarbons in admixture with air. With the exception of methane, for which the maximum speed of flame was 67 cm. per sec., the maximum speeds of flame in air mixtures of these gases were approximately the same, namely, about 82 cm. per sec. In each instance the mixture having the maximum speed of flame contains more combustible gas than is required for complete combustion.—W. P.

Flame; Propagation of — in complex gaseous mixtures. Part III. The uniform movement of flame in mixtures of air with mixtures of methane, hydrogen, and carbon monoxide, and with industrial inflammable gases. W. Payman, Chem. Soc. Trans., 1919, 115, 1451—1462. (See preceding abstracts.)

THE application of the speed generalisation to the calculation of the speeds of the uniform movement of flame in industrial gas mixtures is complicated by the fact that with carbon monoxide, which is usually present in such mixtures, the speed of flame is dependent on the amount of water vapour present. Hydrogen, and any gas into the composition

of which hydrogen enters, acts towards mixtures of carbon monoxide and air in a manner comparable with that of water vapour. Such gases are generally present in industrial gas mixtures in sufficient quantity to render the presence of water vapour negligible. For the calculation of the speeds of flame in these mixtures the "effective speeds" of carbon monoxide-air mixtures can be calculated from the speeds of the flames in mixtures of carbon monoxide, hydrogen, and air, and although the effective maximum speed of carbon monoxide-air mixtures (125 cm. per sec.) was about double the speed found in one series of determinations (60 cm. per sec. at 12° C. and 750 mm., mixture saturated with water vapour), the values so obtained gave good results when used for the calculation of the speeds of complex mixtures. The methods of calculation are applied to simple mixtures of methane, hydrogen, and carbon monoxide taken two or three at a time in admixture with air. A straight coal gas and a producer gas were also examined, the maximum speeds of flame in their mixtures with air being 151 cm. per sec. (17.9% coal gas) and 72.2 cm. per sec. (39.0% producer gas) respectively. The speed of flame in mixtures of air with gas, such as producer gas, containing a large proportion of nitrogen can be calculated on the assumption that the cooling or retarding effect on the flame of excess of air or of nitrogen will be the same, since their specific heats are the same. This assumption is not quite correct, since the presence of reactive gas slightly opposes the retarding effect of air. The presence of a large proportion of nitrogen in the combustible gas has the effect of diminishing the "displacement" of the maximum-speed mixture from the mixture containing combining proportions of combustible gas and oxygen.—W. P.

Ether-alcohol-air and acetone-alcohol-air mixtures; Ignition of — in contact with heated surfaces. A. G. White and T. W. Price, Chem. Soc. Trans., 1919, 115, 1462—1505.

THE "sub-ignition temperatures" of various mixtures of air with ether, alcohol, and acetone have been determined, and also the limits of inflammability of these mixtures. The effect of adding small amounts of glyceryl trinitrate (nitroglycerin) and the peroxides of ether to these mixtures has also been examined, these being possibly present in the vapours from cordite stoves. The mixtures were allowed to flow rapidly into an evacuated tube heated to a known temperature in an electric furnace, the lowest temperature at which inflammation occurred being called the "sub-ignition temperature." It was found necessary to use a fairly long tube with the sealed end projecting well out of the furnace to prevent what the authors term "shock ignition," by means of which ether-air and carbon bisulphide-air mixtures could be ignited at ordinary temperatures. Shock ignition took place when the pressure was suddenly and rapidly equalised in the apparatus. The ignition of dilute ether-air mixtures usually resulted in the luminous, incomplete combustion of the ether (Perkin, Chem. Soc. Trans., 1882) with the formation of what has been termed a "cool flame." Tubes of different diameters were used with different leading-in tubes to bring about different periods of equalisation of pressure. The sub-ignition temperatures may be taken as: ether 187° C., alcohol and acetone about 500° C. The sub-ignition temperatures were lowered with decrease of pressure, and were lower if ethyl hydrogen peroxide were present. They were not affected by the presence of diethyl peroxide or glyceryl trinitrate. The limits of inflammability were determined in glass tubes 2.5 and 5 cm. in diam. and in iron tubes 5 and 15 cm. in diam. The extreme limits found were: ether 1.73% and 23.30%,

alcohol 4.16% and 18.95% (upper limit at 60° C.), and acetone 2.88% and 12.40%. The limits of inflammability of mixtures could be calculated by the Le Chatelier formula (this J., 1919, 126 A) for downward propagation of flame, but deviations were noted for upward and horizontal propagation. The flame travelled steadily only in the case of downward propagation, being often jerked out in the other cases, giving less trustworthy results. Increase of temperature and pressure both widened the limits. Mixtures were made up by a weighing method, but were not analysed before sparking.

—W. P.

Gas producers; Calorific value of the gas formed in the recovery of low temperature tar in —. F. Fischer. Ges. Abhandl. zur Kennt. der Kohle, 1918, 3, 105—108. Chem. Zentr., 1919, 90, IV., 632—633.

WHEN coal yielding 30% of volatile constituents was heated in a tubular retort at 500° C. before being discharged into the main shaft of the gas producer there were obtained, per kilo. of coal, 100 grms. of tar, 50 litres of distillation gases having a heating value of over 8000 cals. per cub. m., and 3.5 cub. m. of producer gas of 1200 cals. per cub. m. In working such a producer, however, in order to obtain as high a yield of tar as possible, a considerable quantity of the producer gas must be drawn through the retort, and the yield will then amount to about 500 litres of distillation gases of 1800 cals. per cub. m., together with 3050 litres of producer gas of 1200 cals. per cub. m. It is far more difficult to wash out all the tar oils from such a diluted distillation gas, and a cooling down of the producer gas proper on addition of the washed distillation gas cannot be avoided. The recovery of the light constituents of the low temperature tar is therefore very difficult in the ordinary Mond producer plant.

—J. F. B.

Purifier installations; Some mechanical aspects of [gas] —. F. R. Parsons. Gas World, 1920, 72, 25—26.

THE present-day tendency in gas purifier construction is towards the provision of a larger superficial area of purifying surface per thousand cubic feet of gas treated. The older type of construction was characterised by the requisite strength and rigidity being accompanied by a sufficiency of elasticity. The modern type of purifier-box is characterised by complete absence of flexibility. The prevailing practice of revivification *in situ* is accompanied by the production of high temperatures within the purifying material. Serious damage may result therefrom owing to expansion of the purifying material. This in general expands in lateral directions only, and causes bulging of the sides or division plate of the purifier. To avoid this it is suggested that one or more V-shaped furrows should be formed in the layer of oxide, to reach across the full width or length of the box. The oxide is furrowed on all four sides of the box, and such furrows afford space for expansion of the oxide.

—J. S. G. T.

[Spent] oxide; Revivification of — in situ. O. B. Evans. American Gas Assoc. Gas J., 1919, 148, 726.

In common gas-works practice 0.75—2% of air is mixed with coal gas, containing 100 grains of hydrogen sulphide per 100 cub. ft., at the inlet of the purifiers for the purpose of continuous revivification of the oxide. In the intermittent method the fouled box is put out of service and a large volume of air blown through the oxide mass. This method has been abandoned by some works on account of the tendency to cause fire, but its use is becoming more general, and it is in common

practice on the Pacific coast. The method is most satisfactory, with ample purification capacity and frequent revivification. To decrease the danger of firing, shallow beds are advised. The admixture of inert gas is helpful and more useful than steam. Cooling the gas is also advised, with the removal of as much as possible of the tar fog. Local heating may be prevented by drawing air through the oxide under slight suction instead of blowing air through. Using this method of working the process has been in use in California for 28 years without a fire or a case of overheating.—W. P.

Petroleum spirit, ether, etc.; Elimination of the danger of ignition of electrically-charged —. D. Holde. Ber. deut. Pharm. Ges., 1919, 29, 569—574.

IN further experiments with Dolezalek's apparatus (this J., 1914, 1147) it was found that when the Leyden jar, containing the electroscope and connected to the vessel into which the petroleum spirit etc. had been forced under pressure, was electrically charged by means of a rubbed ebonite rod the charge was retained for a considerable time even after the vessel containing the petroleum spirit had been earthed. Hence it would seem that in the experiments previously described (this J., 1915, 649) the electroscope attachment immersed in the petroleum spirit had not conveyed any appreciable charge during the introduction of the liquid into the vessel. It was also found that when the insulating property of the petroleum spirit was particularly good the negative charge taken up by the connection between the electroscope and the petroleum spirit vessel could remain there when the vessel was earthed, the petroleum spirit thus playing the part of the glass in the Leyden jar. The conclusions formerly drawn with regard to the dissipation of electrical charges were therefore substantially confirmed. Other experiments indicated that the electrical charges taken up by the petroleum spirit vessel were essentially due to the friction of the liquid upon the walls of the tubes which conveyed it. No electrical charges were taken up when the petroleum spirit was introduced under a pressure of 5—6 atm., with the atmospheric moisture at 75 to 95%, whilst at 57 down to 30% of moisture charges were invariably received. Variations in the atmospheric temperature (13° to 31° C.) had no appreciable influence upon the strength of the charge received or the insulating capacity of the petroleum spirit. Not only the petroleum spirit tank, but also all metal parts in contact with it ought to be earthed as a safeguard against the danger of sparks. In the case of technically pure ether and benzene the conditions in the electrically-charged condition differ somewhat from those observed in the case of petroleum spirit, for these substances can give up high charges to the walls of the vessels and tubes merely in consequence of their own electrical conductivity ($\epsilon = 10^{-9}$ to 10^{-12}).—C. A. M.

Mineral oils; Freezing point of —. E. Lantos. Chem.-Zeit., 1919, 43, 853.

MINERAL oils containing paraffin wax in solution do not answer to the ordinary cryoscopic rules. In the oil industry the real freezing point of oils is not determined, but the so-called "setting point," i.e., the temperature at which an oil placed in a tube, which is chilled in a freezing mixture of snow and sodium hydroxide solution and then turned mouth downwards, does not alter its meniscus for 30 secs. As a rule the smaller the viscosity of an oil the lower is its setting point. On refining two Rumanian oils, however, it was found that although the viscosity was reduced the setting point was raised, e.g., from -20° C. to -15.5° C. Oils of Galician origin (e.g., those from Limanowa) which

contain paraffin wax show high setting points. For example, a refined oil, rich in paraffin wax, with viscosity 2.29, showed a setting point of $+10^{\circ}\text{C}$. On extraction of the wax the viscosity was reduced to 1.85, whilst the setting point was then -20°C . These results point to the conclusion that solutions in which the solvent and dissolved substance are homologous do not obey the cryoscopic laws.—C. A. M.

Fullers' earth [for treatment of mineral oils]; Preparation of —. W. C. Phalen. Chem. and Met. Eng., 1919, 21, 469.

The bleaching action of fullers' earth on mineral oils is independent of its chemical composition, and depends on its power of selective absorption. The following factors are important: The longer the column of earth the better the bleaching effect; the coarser the earth the more rapid the flow and the poorer the bleaching effect; the higher the temperature the faster the flow and the poorer the bleaching effect. Filtration should, therefore, take place at the lowest temperature compatible with the fluidity of the oil. The first burning of the earth should take place at about 600° – 700°F . (315° – 370°C .); this merely removes water and organic matter. There should be no fusion. After use the earth may be revived by further burning at 1050° – 1100°F . (565° – 590°C .); with Florida earth the optimum temperature is 1100° – 1200°F . (590° – 650°C .). Very serious loss in efficiency results from over-burning.—A. E. D.

PATENTS.

Fuel; Manufacture of a solid —. E. K. Koblischek, Vienna. Ger. Pat. 313,469, 30.6.18.

RESIDUES from petroleum refineries consisting of silicates containing paraffin wax are melted and filtered; mineral wax or beeswax is added, and the product is mixed with powdered wood charcoal, together with an oxygen carrier, such as manganese dioxide, barium peroxide, or potassium chlorate. The mass is continuously stirred, poured into moulds at about 50°C ., and allowed to cool. The fuel is easily ignited and burns slowly.

—J. F. B.

Coal; Apparatus for feeding and burning —. E. C. R. Marks, London. From Combustion Economy Corporation, Chicago, Ill., U.S.A. Eng. Pat. 136,121, 21.7.19. (Appl. 18,128/19.)

POWDERED coal is fed by a horizontal screw conveyor into a vertical conduit, through which a stream of air passes upwards. At the point of delivery into the air conduit the coal is fed between two ribbed plates, one of which is stationary and surrounds the delivery orifice, and the other is attached to the rotating conveyor spindle at an adjustable distance from the first plate. The coal is thereby disintegrated and its delivery rendered more uniform. The velocity of the mixed fuel and air remains high until it reaches the burner, the cross-section of the conduit being less than the opening of the burner. A flared connection is interposed between the conduit and the burner. The powdered coal conveyor and the blower for producing the air blast are both driven by the same motor, the former through a variable speed gear, so that the proportion of coal to air may be varied. The volume of air may be varied independently by

a valve in the delivery conduit from the blower, and an indicator may be combined with the valve, graduated in accordance with pre-determined requirements of air blast for different rates of fuel feed. The conduit adjacent to the burner is provided with two annular sets of stationary inclined deflecting blades to ensure complete mixing. The burner opening may be varied by a pair of hinged vanes, one on either side of the opening. The vanes are mounted on hollow trunnions, and water is circulated through them to prevent injury by overheating.—W. F. F.

Fuel; Combustion of —. C. Dellwik, Chorley Ltd., London. Eng. Pat. 136,212, 9.11.18. (Appl. 18,392/18.)

Wood, Herts, and Techno-Chemical Laboratories, POWDERED fuel is introduced by means of a jet of a small quantity of cold air or steam, gas, or vapour into a further volume of air which has been preheated by the waste heat of combustion to a point above the ignition temperature of the fuel. The quantity of air is regulated so that the fuel is burned mainly to carbon monoxide to produce a reducing atmosphere. The use of preheated air ensures that a much larger quantity of heat is available from a given weight of fuel, for maintaining a reducing atmosphere at a given temperature. The hot gases are afterwards passed through regenerators alternately with the air for combustion, so that the latter is heated only by the sensible heat of the combustion products without further combustion of the carbon monoxide.—W. F. F.

Pitch; Combustion of —. Rowntree and Co., Ltd., and F. G. Fryer, York. Eng. Pat. 135,886, 28.9.18. (Appl. 15,809/18.)

PITCH is powdered, mixed with air in regulated amount, and burnt. Since pitch usually contains only about 0.5% of ash, the flame may be used for heating, by direct contact, materials in which it is desirable to avoid contamination by ash.—W. F. F.

Vertical gas retort settings. F. Cummins, Manchester. Eng. Pat. 136,398, 28.2.19. (Appl. 5002/19.)

In order to dispense with the vertical waste gas flues at the back of retorts of the Glover-West type, holes are provided in the floors of all the combustion chambers and circulating chambers at the rear ends of the chambers. The waste gases from each combustion chamber travel upward through the rear ends of the combustion chambers and into the circulating chambers, gas outlets from here to the chimney being controlled by dampers. The number of dampers required is much less than in the usual type of setting.—W. P.

Gas producing [and steam generating] plant. W. Climie, Ayr, and W. Lees, Glasgow. Eng. Pat. 135,959, 9.12.18. (Appl. 20,392/18.)

In a complete gas producing and steam generating plant the gas producer is contained within a steam generator designed and of sufficient strength to generate steam at a pressure capable of performing all the work desired. The generator supplies steam to a steam engine, which is used for operating the fuel elevator, the air blow, the fuel rake, and the purifier pump. The steam pipe from the generator is provided with a by-pass and a surplus valve, the steam generated in excess of that taken up by the engine being led away and utilised as desired.

—W. P.

Gas; Production of [mixed] —. S. N. Wellington, London. Eng. Pat. 136,186, 30.7.17. (Appl. 10,972/17.)

A MIXED gas for industrial purposes consists of an admixture of a rich gas obtained by the destructive

distillation of coal at a comparatively low temperature (400° – 620° C.), with producer gas having an approximate calorific value of 125–150 B.Th.U. per cub. ft. The gases are mixed in the proportions necessary to give a power gas of a calorific value of 300 B.Th.U. per cub. ft.—W. P.

Gasous fuels; Apparatus for use in mixing — S. N. Wellington, London. Eng. Pat. 136,200, 30.7.17. (Appl. 13,737/18.)

In order to maintain the calorific value of a mixed gas (see preceding abstract) approximately constant, use is made of a calorimeter, which automatically varies the proportion of one of the gases admitted to the mixing chamber. This calorimeter consists of two tanks containing liquid, within which floats are immersed suspended from opposite ends of a beam. Beneath one tank a supply of the mixed gas is drawn off and burned. The expansion of the liquid raises the surface of the liquid and the float in this tank. The beam is provided with a contact arm operating between two contacts corresponding, for example, to the values 310 B.Th.U. and 290 B.Th.U. These electrically control a water cock, which admits or releases water from the water-loaded governor controlling the admission of the low temperature gas into the mixing chamber.

—W. P.

Producer gas plant. A. H. Lynn, London. Eng. Pat. 136,189, 2.3.18. (Appl. 3715/18.)

A CYLINDRICAL vessel is divided by a partition into two superposed compartments, each provided with gas inlet and outlet, and serves as a gas cooler and an air-heater and saturator. Liquid for cooling the gas is circulated through the upper compartment and passes by gravity through the lower compartment for preheating and saturating the air with water vapour. (See also Eng. Pats. 11,452 of 1912 and 744 of 1913; this J., 1912, 1167; 1913, 1147.)—W. P.

Gas producers. H. W. Bamber and E. Goldsmid-Abrahams, London. Eng. Pat. 136,333, 13.1.19. (Appl. 901/19.)

THE velocity of the exhaust gases from an internal combustion engine is used to induce a current of air through the fire of a gas producer when starting up. The combustion engine is operated temporarily with petrol, paraffin, or coal gas as fuel.—W. P.

Purifying gas and obtaining valuable by-products therefrom; Methods of and apparatus for — F. A. Umsted, Chicago, U.S.A. Eng. Pat. 135,931, 3.12.18. (Appl. 20,002/18.)

DURING purification the gas passes through a series of contiguous chambers arranged to form one complete apparatus, and is subjected to two distinct series of processes. The first series consists in fractionally cooling the gases in order to remove the heavy constituents in successive stages, during which the gases do not come into contact with the cooling liquid. The desired temperatures are maintained automatically. In the second series purification is effected by direct contact with suitable reagents and by filtration. The method of purification is designed primarily to deal with the gases obtained by the dry distillation of waste material, such as municipal waste, sewage, street sweepings, peat, sawdust, etc.—W. P.

Hydrocarbons; Continuous and uniform treatment of — with sulphurous acid. Allgem. Ges. für Chem. Industrie, Berlin. Eng. Pat. 114,845, 9.4.18. (Appl. 6067/18.) Int. Conv., 21.3.17.

UNIFORMITY in the supply and discharge of the liquid sulphur dioxide is achieved by the provision of intermediate vessels, which are placed between the main and auxiliary evaporators and between the

latter and the discharge pumps. Pressure equalisers and supply pipes connect the main evaporators to the intermediate vessels, and gauge glasses indicate the progress of the operations, which must be so controlled that no more sulphur dioxide flows into the evaporators from the mixing chamber than is removed therefrom.—A. E. D.

Petrol; Production of — F. Tinker, Birmingham. Eng. Pat. 135,015, 19.12.18. (Appl. 21,289/18.)

CRUDE oil is distilled and the vapour produced is passed into a superheater or cracking chamber, on leaving which it is brought into contact with the crude oil entering the still. Heat interchange is thereby effected, the vapour passing into a dephlegmator, and the "topped" crude oil being directed into the still.—A. E. D.

Low-boiling oil; Manufacture of — from higher boiling petroleum or related oil. E. B. Cobb, Jersey City, Assignor to Standard Oil Co., Bayonne, N.J. U.S. Pats. (A) 1,322,878 and (B) 1,322,762, 25.11.19. Appl., (A) 25.4.14, and (B) 4.10.19.

(A) THE oil is distilled with anhydrous aluminium chloride, which is dissolved in part of the oil under treatment. The process is so conducted that only the minor part of the carbon content of the oil remains as coke. (B) The distillation as above is continued until the residue remains only just sufficiently fluid to be withdrawn as a liquid. This residue is washed with water and there is obtained oil together with coke and an aqueous solution of aluminium chloride.—A. E. D.

Oil from oil-bearing shale; Apparatus for distilling oil from — H. R. Straight, Adel, Iowa. U.S. Pat. 1,323,204, 25.11.19. Appl., 31.7.18.

A SERIES of cars which carry the shale travels through a brick chamber so arranged that the lower half is a combustion space, whilst the upper half is a vapour space. Sealing devices separate the successive cars, which themselves divide the chamber horizontally into the vapour and combustion sections.—A. E. D.

Gasoline from hydrocarbon gases; Process of obtaining — H. C. Cooper, Clarksburg, W. Va., Assignor to Hope Natural Gas Co., Pittsburgh, Pa. U.S. Pat. 1,323,837, 2.12.19. Appl., 18.1.17.

THE gas is first subjected to a spray and subsequently to liquid gasoline-absorbing menstruum. The gasoline is finally separated from the solvent. —A. E. D.

Gasoline; Process of manufacturing — A. D. Smith, Vinita, Okla., Assignor to J. T. Milliken, St. Louis, Mo. U.S. Pat. 1,324,075, 9.12.19. Appl., 16.10.15.

IN the process for manufacturing gasoline from oils of the paraffin series described in U.S. Pat. 1,239,423 (this J., 1917, 1125) the pressure in the still, i.e., 125–150 lb. per sq. in., is maintained on the vapours during condensation and on the condensed liquid in the receiving tank. The condensed liquid is drawn off and immediately mixed with low gravity naphtha, without reducing the pressure, to prevent loss of the more volatile hydrocarbons.

—L. A. C.

Petroleum and other oils; Process for obtaining distilled products from — Apparatus for obtaining distilled products, particularly gasoline, from petroleum and other oils. A. A. Stapp, Denver, Colo. U.S. Pats. 1,324,212 and 1,324,213, 9.12.19. Appl., 4.12.17.

IN the continuous production of low-boiling hydrocarbons, such as kerosene, benzine, and gasoline, from petroleum oils, the oil is first heated to a tem-

perature sufficient only to remove the gasoline fraction; the residual oil passes into a vaporiser and thence into a cracking tube. The vapours from the cracking tube are separated by fractional condensation into gasoline and high-boiling hydrocarbons, and the latter fraction is returned to the vaporiser. The uncondensed gas produced both during the initial heating of the oil and in the cracking treatment is superheated and mixed with the vapours undergoing the cracking treatment.

—L. A. C.

Liquid fuel. A. A. Backhaus, Baltimore, Md., Assignor to U.S. Industrial Alcohol Co. U.S. Pat. 1,324,765, 9.12.19. Appl., 28.11.17.

A PETROLEUM distillate and alcohol are blended by means of carbon bisulphide.—W. J. W.

Hydrocarbons; Conversion of —. R. Fleming, Swampscott, Mass., Assignor to The Richard Fleming Co. U.S. Pat. 1,321,766, 9.12.19. Appl., 17.11.16.

A COLUMN of heavy liquid hydrocarbon is heated to its boiling point under a pressure of 75 lb. and above, the vapour of a lower boiling hydrocarbon being at the same time passed through it during a prolonged period. The resulting vapours are thus heated above the cracking point under a pressure sufficient to retard formation of unsaturated hydrocarbons and gases.—W. J. W.

Hydrocarbons; Process and apparatus for treating —. R. R. Rosenbaum, Chicago, Ill. U.S. Pat. 1,324,983, 16.12.19. Appl., 3.10.17.

CRUDE hydrocarbons are heated in a still, and the vapours are separated by fractional condensation into two portions. The lighter fraction is collected, and the heavier fraction is superheated "under sufficient pressure to store kinetic heat energy therein," and is returned to the bottom of the still, where it vaporises. The "liberated kinetic heat energy" breaks up the vapours and any oil in the still, liberating further quantities of the lighter fraction.—L. A. C.

Mineral oil of high boiling point; Process of converting — into products having lower boiling points. R. Koetschau, Waldheim, Germany, Assignor to The Chemical Foundation, Inc. U.S. Pat. 1,325,299, 16.12.19. Appl., 19.3.14.

In the treatment of mineral oils of high boiling point with a catalyst to obtain products of lower boiling point the oils are subjected during the time of contact with the catalyst to the action of a material capable of increasing the speed of the catalytic reaction. For example, the oils are treated with the hydrocarbon addition products of an aluminium halide.—L. A. C.

Gaseous fuel burners. A. C. Ionides, jun., London. Eng. Pat. 136,296, 19.12.18. (Appl. 21,314/18.)

Fuel; Liquid —. E. C. R. Marks, London. From U.S. Industrial Alcohol Co., New York. Eng. Pat. 136,452, 5.5.19. (Appl. 11,177/19.)

Ammonia. U.S. Pat. 1,321,979. See VII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Charcoals; Some chemical characters of ancient —. T. C. Cantrill. *Archæol. Cambrensis*, 1919, 365—392.

THE charcoals (i.e., charred and blackened wood)

found in the course of archaeological excavations are much more readily attacked by nitric acid and potassium chlorate and by hypochlorite solution than are charcoals produced under modern conditions (true charcoals); the ancient charcoals differ amongst themselves as regards their solubility, bleaching, and disintegration when treated with the reagents mentioned, but this may be due to the varying species of wood from which the charcoal was derived. The author adduces evidence, chemical and physical, to show that there is no reason to doubt that the ancient charcoals were produced by the action of heat or fire, and that the blackening of the wood was not caused by the action of peaty soils.—W. P. S.

Decolorising carbon; Preparation of — by prolonged heating. C. E. Coates. *Lat. Bull.*, 161, 8.

IT is stated that ordinary wood charcoal from sawdust (the decolorising power of which is very slight) may be converted into a carbon equal in efficiency to "Norit" by prolonged heating at 1200° C. in a closed crucible (cf. Ger. Pat., 250,741; this J., 1912, 1022).—J. P. O.

PATENTS.

Incandescent gas mantles; Material for strengthening and increasing the luminosity of —. H. Pope, Tibshelf, Derby. Eng. Pat. 135,797, 25.6.19. (Appl. 15,939/19.)

YELLOW resin, 1 part, washing soda, 4 parts, and chalk, 10 parts, are ground to a powder, and the mixture used alone or formed into a liquid with methylated spirit, for treating incandescence gas mantles.—B. N.

Filaments for electric lamps. Westinghouse Lamp Co., Bloomfield, N.J., Assignees of R. D. Hall, East Orange, N.J., U.S.A. Eng. Pat. 121,596, 27.11.18. (Appl. 19,595/18.) Int. Conv., 19.12.17.

THE refractory metal of the filament, e.g., tungsten, is mixed, during the process of manufacture, with 2—7% by volume (2.5—10% by weight) of silica, and either 1—5% by volume (2—10% by weight) of alumina or 0.1—0.4% by volume (0.05—0.2% by weight) of thorium.—B. N.

Distilling shale. Eng. Pat. 136,076. See X.

III.—TAR AND TAR PRODUCTS.

Benzene; Effect of pressure and of dissolved air and water on the melting point of —. T. W. Richards, E. K. Carver, and W. C. Schumb. J. Amer. Chem. Soc., 1919, 41, 2019—2028.

BENZENE saturated with air under atmospheric pressure melts 0.003° below the true triple point, and the freezing point is not much changed by pressure. An increase in pressure on benzene free from air changes the freezing point 0.029° per atmosphere. Saturation with water lowers the freezing point of benzene 0.095°. The true freezing point of benzene saturated with air is 5.493° C., and the true triple point 5.496° C.—J. F. S.

Toluene; Criteria of the degree of purity of commercial —. J. S. Lumsden. *Chem. Soc. Trans.*, 1919, 115, 1366—1372.

COMMERCIAL toluene contains varying amounts of a liquid which cannot be nitrated. This liquid was not isolated, but for the tests described the assumption was made that it may be represented by a paraffin mixture which boils close to the boiling point of toluene. By fractionation of petrol a quantity of such a liquid was obtained boiling at 108°—112° C. Pure toluene at 15° C. was found to

have sp. gr. 0.8712, the paraffin mixture sp. gr. 0.743. There is no change of volume on mixing toluene and paraffin, and the determination of the density of commercial toluene gives a fair indication of the percentage of impurity present, 1% of paraffin producing a lowering of sp. gr. by 0.0013. The estimation of toluene by the temperature of miscibility with acetic acid as described by Orton and Jones (this J., 1919, 811 A) is too complicated for commercial use. A modified method is described, which is quickly carried out, and although only comparative is trustworthy. Nitration and estimation of the excess nitric acid by the nitrometer is believed to be the most accurate test, and the weighing of the solid after nitration gives the actual practical yield of nitro-compound. Nitration was effected by means of potassium nitrate and sulphuric acid, the reaction stopping quantitatively when all the toluene had been converted into the dinitro-compound. By none of the methods, under ordinary conditions of working, can an accuracy closer than 0.5% be expected.—W. P.

Phthalic anhydride. H. D. Gibbs. J. Ind. Eng. Chem., 1911, 41, 1031—1032.

In experiments on the oxidation of the methyl group of toluene, mixtures of oxygen and toluene and of atmospheric air and toluene were subjected to contact with various catalysts at temperatures from the boiling-point of toluene to about 550° C. The oxides of the metals of the fifth and sixth groups of the periodic system were the most effective catalysts, vanadium being the best and molybdenum the next best. Similar reactions were applied to the manufacture of phthalic anhydride from naphthalene (Gibbs and Conover, Eng. Pats. 119,517 and 119,518; this J., 1918, 684 A), and the conditions to obtain the optimum yield have been determined. The best laboratory results showed 82% of the theoretical conversion. The phthalic anhydride produced is remarkably pure and is quite free from chlorine or sulphur compounds which were common impurities in the phthalic anhydride formerly on the market. (See also this J., 1920, 57 A.)—C. A. M.

Emulsification by adsorption at an oil [nitrobenzene] water interface. S. E. Sheppard. J. Phys. Chem., 1919, 23, 634—639.

Emulsions of nitrobenzene in sulphuric acid and hydrochloric acid may be readily prepared by making the acid of the same density as the nitrobenzene. Similar moderately stable emulsions may be prepared by using as aqueous medium sulphuric acid saturated with lead sulphate or calcium sulphate, or hydrochloric acid saturated with lead chloride or sodium chloride, in both cases the acid solution being of the same density as the nitrobenzene.—J. F. S.

Carbonising variations. Middleton. See IIa.

PATENTS.

Fractionation of crude benzol and the like; Process and apparatus for the continuous distillation and —. E. C. R. Marks, London. From Soc. Franco-Belge de Fours à Coke, Brussels. Eng. Pat. 136,450, 1.5.19. (Appl. 10,864/19.)

A SINGLE distilling column receives crude benzol at the top and steam at the bottom; mixtures of water and benzol vapours are taken off at various levels

from top to bottom and immediately condensed. After separating the water the benzol fractions are of commercial quality, and uniformity of products with varying crude benzol can be maintained by adjustment of valves in the pipes leading from the still to the condensers.—B. M. V.

Ortho- and para-toluene sulphonic chlorides; Process for separating —. F. E. Matthews and E. H. Strange, London. Eng. Pat. 135,987, 20.12.18. (Appl. 21,402/18.)

TOLUENE-*o*-SULPHONIC CHLORIDE is separated from mixtures of the ortho and para isomerides, containing 60–70% of the former (such as are obtained by cooling the sulphonation mixture to –20° C. and separating the para compound which crystallises out) by seeding the liquid mixture at a temperature a few degrees below 0° C., e.g., –6° C., with a crystal of the ortho-sulphonic chloride, and removing the crystals which separate out by centrifuging or other suitable means.—G. F. M.

Quinone and quinol; Method and apparatus for the production of —. F. T. Kitchen, West New Brighton, N.Y., Assignor to K. and T. Chemical Corporation, New York. U.S. Pat. 1,322,580, 25.11.19. Appl., 3.3.16. Renewed 3.4.19.

BENZENE is introduced into the lower part of an electrolytic tank containing an electrolyte of greater specific gravity, so that it rises through the liquid and is at the same time oxidised at the anode to quinone, which dissolves in the excess of benzene employed. The solution thus obtained is continually subjected to the electrolytic oxidation until the concentration of quinone becomes sufficiently high. The apparatus also comprises a reducing tank into the lower part of which the quinone solution is introduced, and means are provided for increasing the intimacy of contact between this and the reducing agent.—G. F. M.

Toluene; Manufacture of —. B. T. Brooks, Pittsburgh, Pa., Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,324,143, 9.12.19. Appl., 10.6.15.

TOLUENE is prepared by reacting on a high-boiling aromatic hydrocarbon with a catalytic material, distilling off the toluene, and condensing the vapours formed to obtain benzene, which is added to another charge of high-boiling aromatic hydrocarbon, the above operation being then repeated.—G. F. M.

Aromatic bodies; Oxidation of —. C. E. Andrews, Assignor to The Selden Co., Pittsburgh, Pa. U.S. Pat. 1,324,715, 9.12.19. Appl., 25.5.18.

AROMATIC hydrocarbons are oxidised by heating with sulphuric acid and a catalyst containing a compound of vanadium or molybdenum.—G. F. M.

Anthraquinone; Purification of crude —. C. E. Andrews, Assignor to The Selden Co., Pittsburgh, Pa. U.S. Pat. 1,324,716, 9.12.19. Appl., 1.7.18.

ANTHRACENE is separated from anthraquinone by vapourising into a current of gas at about 300° C. a part at least of the mixture and separately crystallising at different locations the volatilised substances.—G. F. M.

Anthracene press-cake; Treatment of —. C. E. Andrews, Assignor to The Selden Co., Pittsburgh, Pa. U.S. Pat. 1,324,717, 9.12.19. Appl., 1.7.18.

AN improved recovery of methylanthracene, phenanthrene, and anthracene is obtained by heating the press-cake to about 200° C. in a current of gas, and gradually cooling the vapours to produce crystallisation at different locations.—G. F. M.

Combustion of pitch. Eng. Pat. 135,886. See IIa.

IV.—COLOURING MATTERS AND DYES.

Dyes; Explosibility and inflammability of —. B. Humiston, W. S. Calcott, and E. C. Lathrop. *J. Ind. Eng. Chem.*, 1919, 11, 1075—1076.

ANY risk in the drying of dyestuffs is due to the increased temperature, since little dust is produced in the process. A rise in temperature may cause oxidation leading to spontaneous ignition, as in the case of Sulphur Black, or there may be decomposition, with the evolution of gases, as in the case of Victoria Green. In the decomposition of the latter dyestuff an exothermic reaction sets in, and the gases might become explosive in a closed space. The apparatus used for studying these properties was a large test-tube, enclosed in an air-bath. A small amount of the dyestuff was heated in the test-tube, through which a slow current of air passed, while a thermo-couple was immersed in the dyestuff, and a note was taken of the temperature at which the latter ignited. A similar apparatus was used for determining the danger of decomposition of the dyestuff, but no air was passed through the tube, and the gases given off were conducted to a gas burette. The point of initial decomposition was noted and whether the decomposition was endothermic or exothermic. The temperature at which the drying plant should be worked should, as a rule, be 25°—30° C. below that of the exothermic decomposition or ignition of the particular dyestuff. In grinding machines of the ball mill type temperatures up to 75° C. may be experienced, and over 100° C. in the impact crushing type of mill. Using apparatus of the type employed by the U.S. Bureau of Mines for determining the explosibility of mixtures of coal dust and air, the explosion points of mixtures of dye dusts with varying quantities of air ranged from 400° to 1100° C., duplicate determinations agreeing within about 50° C. The results agreed fairly with experience in the works as to the relative safety of the different dyes examined. More accurate results were obtained by the use of an apparatus consisting essentially of a large test-tube, fixed in an air bath, and having a tube for the introduction of air to the bottom of the test-tube. The latter was gradually heated while a current of air sufficiently rapid to keep the tube constantly filled with dust was admitted, and the temperature of decomposition was noted. The temperatures obtained with the same series of dyestuffs as tested in the Bureau of Mines apparatus ranged from 250° to 550° C., and duplicate determinations agreed within 10°—15° C. In the standardisation of dyestuffs an additional factor is introduced in the possibility of a reaction between the standardising reagent and the dyestuff. For example, the accidental addition of soda ash to Victoria Green would probably cause a reaction with the oxalic acid in the dyestuff, which might raise the temperature to the decomposition point of Victoria Green.—C. A. M.

Dyes; Problems in the identification of —. E. F. Hitch and I. E. Knapp. *J. Ind. Eng. Chem.*, 1919, 11, 1076—1078.

THE composition of azo-dyes may often be determined by reduction and isolation and identification of the products of the reduction, but amino-derivatives of second components are not easily separated or identified. For the separation and identification of components in a mixture, microscopical examination, fractional dyeing, solution tests with alcohol and water, and extraction with immiscible solvents may be employed. In some cases mixtures may be separated by adsorption on kaolin, talc, etc., followed by washing with water or alcohol. For the separation and identification of mixtures on the fibre methods of fractional reduction, extraction with various solvents, and spectro-

scopic examination may be used. The quantitative results obtained by means of the spectrophotometer would be sufficient to identify a dyestuff, but for this purpose it would be necessary to obtain the data of the absorption bands of a large number of pure dyestuffs by means of a calibrated instrument.—C. A. M.

Dyestuffs; Estimation of the strength of —. W. H. Watkins. *J. Ind. Eng. Chem.*, 1919, 11, 1079—1080.

THE principal causes of disagreement between seller and buyer in the case of dyestuffs are differences of standard and variations in samples due to incomplete mixing of the dyestuff with the inert material. The preparation of the solution used in dyeing tests may also affect the apparent strength. As a rule a little dilute acetic acid should be used with basic dyes. The influence of hard water upon a dyestuff has led to disputes between buyer and seller, especially when the dyestuff is partly in the form of its calcium salt, and a little soda has been used to correct this and to neutralise the effect of hard water. In such cases if the solution is not heated at a sufficiently high concentration complete conversion of the calcium salt into the sodium salt may not be effected, so that the former will not contribute to the dyeing process. Tests of the accuracy of judgment of an experienced dyer have shown that he will usually not be able to detect variations of less than 3%.—C. A. M.

Red pea gall; Colouring matter of the —. M. Niedenstein. *Chem. Soc. Trans.*, 1919, 115, 1328—1332.

THE red colouring matter of the red pea gall was isolated by extracting the de-fatted and powdered gall with boiling alcohol and precipitating the tannin from the aqueous solution of the extract by the addition of caseinogen. The purified and recrystallised substance, to which the name dryophantin is given, formed deep-red glistening needles, melting at 219°—220° C., and having the empirical formula $C_{23}H_{28}O_{15}$. Its alcoholic solution gives a red precipitate with ferric chloride, whilst ammonia and alkali hydroxides produce a colour change to deep blue, which once more becomes red on acidification. On hydrolysis with sulphuric acid dryophantin yields 2 mols. of dextrose and 1 mol. of purpurogallin,

The substance is therefore not an anthocyanin, and as the other so-called anthocyanins of plant galls are probably of a similar nature, it is proposed to classify these red pigments in a new group of organic colouring matters, to which the name gallorubrones is assigned.—G. F. M.

Electrochemical production of organic compounds. Thatcher. See XI.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Vegetable fibres; Economy of cellulose and caustic soda in the isolation, purification, and bawking of —. M. Freiburger. *Deut. Baumwollind.*, 1919, 1, 38, 55. *Chem.-Zeit.*, 1919, 43, Rep., 292.

IN the treatment of cotton with caustic soda by various methods the loss of weight owing to the solubility of the cellulose in the caustic lye or to the formation of oxycellulose, if the cotton is not properly de-aerated, may be extremely large, especially in the case of strong caustic liquors. A regenerated lye, re-causticised, and decolorised by oxidising agents, still contains sufficient reducing substances to protect the cellulose against a large loss of weight, but not such as to stain it during

bowking, and such a lye gives better results than either fresh caustic liquor or old spent liquors. The regeneration of spent liquors also effects an economy in caustic soda, as these liquors can be used several times in succession.—J. F. B.

Soda pulp [washing]; Report of committee on —. M. L. Griffin. Paper, 1919, 25, 132—138.

It is important in washing the pulp to conserve the original concentration of the black liquor with as little dilution as possible. The ideal way would be to squeeze out the original liquor thoroughly and then wash out the remainder by counter current in a closed system. This is not realised in any known system, but the author suggests the possibility of using a cage through which the wet material is forced by a screw propeller, squeezing out the fluid contents and delivering the mass relatively dry. If such machines were arranged in multiple series, the material being mixed with dilute liquor or water between successive squeezing units, the process could be made continuous. In the ordinary system the choice lies between a large number of shallow washing tanks in which washing can be quickly performed but with considerable dilution of the liquor, and a smaller number of deep tanks in which the time required to wash the pulp is unduly prolonged. The best method is to work between these two extremes, using a closed system of small connected tanks operated in a cycle, each tank being cut out, discharged, recharged, and connected up again in turn. When using open pans it is convenient to have them of such dimensions that each pan will hold the contents of one digester. Rectangular pans are most generally used; for a charge of about 5200 lb. of soda pulp, a wash-pan of 18×16×5 ft. is suitable. The pans are provided with perforated plates leaving a space of 6 ins. above the bottom from which a 4- or 6-in. pipe leads to the distributing main, with gate valves communicating with the strong liquor tank, the weak liquor tank, or the drain. Each pan has a 10-in. wash-out main at each end, through which the drained pulp is washed to the screens. In the separate washing system each pan drains independently of the others; in some mills there are two strong liquor tanks and one weak. The liquor in the first strong liquor tank is used for rinsing out the next digester, whilst that collected in the second is sent to the recovery plant. The original liquor has a density of 12° B. (sp. gr. 1.086) at 15° C., and the washings are collected in the strong liquor tank for recovery until the density falls to 5° B. (sp. gr. 1.034), after which they are collected in the weak liquor tank until they test 1° B. (sp. gr. 1.007). The average density of strong liquor sent to the evaporators is 9° B. (sp. gr. 1.063). In working the cycle system the average density of liquor to the evaporators is 10.25° B. (sp. gr. 1.072), and this indicates a considerable economy of coal, but the time required for washing is considerably longer. If the pulp is allowed to remain in contact with the black liquor its colour suffers permanently. A great advantage is gained by washing the stock with hot water.—J. F. B.

Sulphite-cellulose waste liquors. W. Philippsthal. Umschau, 1919, 23, 718—719. Chem.-Zeit., 1919, 43, Rep., 292.

SULPHITE pulp waste liquor is said to contain substances which act as a protection against rodents, and it may be used as a dressing for textiles. In the manufacture of artificial stones from marble cement small additions of sulphite lye to the water increase the absorption by 30%, and the finished stone possesses greater strength. A paste of china clay which has been rendered more fluid by addition of sodium carbonate solution becomes stiffer again on addition of traces of sulphite liquor. The liquor

may also be used as a catalyst in the manufacture of rubber. Clayey soil is used for minor building purposes, but does not bind well with lime mortars. If milk of lime be mixed with sulphite liquor and the loam or clay stirred in, then slabs made of the resulting material can be built up like ordinary bricks with lime or cement mortars. A little sulphite liquor should be mixed with the mortar to obtain better binding. Existing structures may simply be coated with a mixture of milk of lime and sulphite liquor.—J. F. B.

Starch in paper; Estimation of —. II. Determination of dextrins in the presence of beater starch. O. Kamm and F. H. Tendick. Paper, 1919, 25, 460—461.

THE starchy matter present in paper may be partly in the form of normal starch added to the pulp in the beating engine, and partly in the form of modified starch or dextrin applied to the surface of the paper in the process of tub sizing. The modified starch may be extracted from the paper by digesting 5 grms. of the sample with 200 c.c. of water at 60° C. for 45 minutes. The extract is filtered off under suction, and the soluble carbohydrate is hydrolysed by acid and the sugar estimated by Fehling's solution. The normal starch remaining in the paper may then be extracted by means of dilute acetic acid according to the method previously described (this J., 1919, 757 A). The separation of the two types of starch is sufficiently accurate for practical purposes. A small quantity of normal starch, amounting to 0.2—0.3% on the paper, is extracted along with the modified starch by the water at 60° C.—J. F. B.

PATENTS.

Cotton bolls; Process for maturing —. F. D. Maisch. Philadelphia, Pa. M. F. Maisch, executrix. U.S. Pat. 1,317,983, 7.10.19. Appl., 19.5.15.

IMMATURE or frost-bitten cotton bolls are subjected to a heated atmosphere above 100° F. (38° C.), whereby the shell of the cotton boll is contracted and caused to open and liberate the cotton, which is then expanded by evaporating the moisture under the continued application of the heat.—J. F. B.

Hood; Textile fibre from —. K. Mutter, Triptis. Ger. Pat. 305,141, 11.11.17.

THE fibres are isolated only from the summer wood portions of the annual rings, which contain the strongest fibres. The annual rings are peeled off from the woody stem and are freed from the soft, fibreless layers of the spring growth. The coherent layer of summer growth is treated chemically for the removal of the whole or a part of the lignin and resins, and the resulting cellulose fibres are isolated by a mechanical treatment.—J. F. B.

Basket or binding material [from hop stems]; Manufacture of a —. Chem. Bleicherei E. Jetter, Ortrand. Ger. Pat. 306,307, 14.11.17.

THE woody residues of hop stems from which the fibrous bast has been removed are boiled for about 6 hours under high pressure with caustic soda solution of 3°—4° B. (sp. gr. 1.020—1.027). The hop stems become sufficiently soft and pliable for basket-making after a single treatment, and if treated twice or more the material becomes completely pliable and can be used for binding.—J. F. B.

Lupin stems; Manufacture of textile fibres from —. Hoffmanns Stärkefabriken A.-G., Salzdahl. Ger. Pats. (A) 306,362, 28.10.17, and (B) 306,496, 24.5.17.

(A) LUPIN stems are boiled with water and then submitted to a fermentation process. The time required for retting in the ordinary way is 14—21

days, but if the stems be boiled for 15–30 minutes and then retted, the fibre is ready for stripping after 4–8 days' retting. (a) The raw material is boiled with dilute aqueous salt solutions, then washed, dried, and worked up in the usual way. Salts of the alkali metals with inorganic or organic acids may be used or cheap waste salt solutions from the Stassfurt district.—J. F. B.

Straw, grasses, etc.; Process for obtaining textile fibres from —. C. Wolf, Schweinsburg, and E. Trommer, Crimmitschau. Ger. Pat. 307,688, 9.4.18.

ONLY the upper parts of the stems containing the finer fibres are employed for the manufacture of textile fibres by digestion with alkalis. These upper portions may be again subdivided in order to obtain materials for fine and coarse spinning. The lower portions of the stems are used for litter or other agricultural purposes.—J. F. B.

Textile yarns; Manufacture of durable —. M. Müller, Limbach, and S. Herzberg, Charlottenburg. Ger. Pat. 313,520, 15.1.18.

STRING, rope, etc., or the constituents used in preparing them, particularly materials composed of paper yarn, are coated with metals by the spraying process. The metal-coated textiles are distinguished by a high tensile strength and resistance to external influences.—J. F. B.

Viscose threads; Machine for spinning, washing, and drying —. M. Denis, Mons, Belgium. Eng. Pat. 125,394, 8.4.19. (Appl. 8878/19.) Int. Conv., 8.8.13.

THE viscose is fed through one of a pair of interchangeable filter-boxes into a bent glass tube which delivers it to the squirting nozzle directed upwards. The coagulating liquid is contained in a vessel shaped like a test-tube which can be adjusted vertically in any desired position to afford a suitable immersion of the nozzle in the bath. The coagulating liquid is continuously circulated through inlet and overflow pipes with flexible connections. The thread passes upwards out of the bath and is caught by hooks attached to an endless travelling metallic web, preferably of aluminium, on which it travels downwards in an inclined path. During its passage in contact with the web the thread is sprayed by various suitable liquids, e.g., a fixing and a washing liquid, which are collected in troughs arranged behind the wire-cloth support. At the bottom the thread is detached from the web by a jet of liquid directed through the latter in the reverse direction, and is passed through a drying chamber while supported by a similar web travelling upwards through a current of hot air.—J. F. B.

Cellulose acetate; Flexible product having a base of —. J. Dupont, Assignor to Soc. Anon. des Etablissements J. Dupont, Argenteuil, France. U.S. Pat. 1,317,276, 30.9.19. Appl., 18.1.18.

A PLASTIC composition is made with cellulose acetate to which a mixture of *o*- and *p*-hydroxybenzyl alcohols has been added.—J. F. B.

Cellulose formations; Process for producing —. P. Minck, Hermsdorf, Germany. U.S. Pat. 1,317,306, 30.9.19. Appl., 2.9.14.

A CUPRAMMONIUM solution of cellulose is projected into a precipitating bath containing copper carbonate and an alkali hydroxide.—J. F. B.

Paper or paper board. E. C. R. Marks, London. From Cedaroid Co., Inc., Rochester, N.Y., U.S.A. Eng. Pat. 133,732, 11.9.18. (Appl. 14,784/18.)

PAPER or paper board intended for containers or receptacles, or for keeping away insects or germs,

is made by the incorporation with the paper pulp of an odorous substance or essential oil, mixed with a suitable substance to promote emulsification. A mixture suitable for tobacco paper is composed of: water, 25; cedar oil, 25; sugar, 15; liquorice, 10; vinegar, 10; alcohol, 10; and glycerine, 5. This mixture is slowly added, in the proportion of 10–20 to the pulp in the beater.—J. F. B.

Paper-size and process of making same. J. A. De Cew, Montreal, Canada. U.S. Pat. 1,317,616, 30.9.19. Appl., 31.5.17.

ROSIN soap containing over 25 of free rosin is diluted and then discharged into a cold solution of sodium silicate until the total dilution corresponds approximately to 2 of total solids.

Paper product and process of making same. J. A. De Cew, Montreal, Canada. U.S. Pat. 1,317,618, 30.9.18. Appl., 15.1.18.

WATERPROOF paper is made by incorporating with the paper stock, as a sizing agent, a precipitated mixture of wax, rosin, and alumina, then drying the product, and heating to the fusion temperature of the sizing mixture.—J. F. B.

Paper-size; Process of treating —. J. A. De Cew, Montreal, Canada. U.S. Pat. 1,317,619, 30.9.19. Appl., 15.4.18.

A SUFFICIENT quantity of alkali is added to the paper stock in the beaters or mixers so that the concentration of the basic ions will prevent the formation of alkaline-earth resins by the salts existing in solution; a resin size is then added and precipitated by aluminium sulphate.—J. F. B.

Paper for spinning, paper yarns, and fabrics; Process for softening —. C. Hasenbring, Hamburg. Ger. Pat. 300,695, 6.1.17.

THE goods are treated with a relatively strong solution of calcium chloride and then rinsed in such a manner that the calcium chloride is not completely removed. Alternatively the goods may be impregnated with a smaller quantity of a dilute solution of calcium chloride and then stoved without washing. The treated material has a soft and slightly soapy feel, and the tensile strength is scarcely affected.—J. F. B.

Paper yarn fabrics; Process for compacting —. F. Rawitscher, Berlin. Ger. Pat. 301,361, 3.5.17.

THE finished fabric is subjected to a prolonged boiling treatment in order to convert its constituent yarns into a permanently swollen condition. If the boiling be continued for a sufficient length of time, the swollen condition of the individual threads becomes fixed without destroying their twist. Even if the strength of the single threads is diminished by this treatment, that of the complete fabric is rather increased thereby, owing to the fact that the yarns of the fabric are considerably compacted. If it be desired to compact the fabric without making it more absorbent, the treated fabric may be impregnated with some water-repellent substance.—J. F. B.

Paper textiles and articles made therefrom; Waterproof impregnation of —. M. Linke, Remscheid. Ger. Pat. 305,024, 26.6.17.

PAPER fabrics or the stitched articles made up from them are steeped in water until they show no further shrinkage, and are then treated, slightly damp or after drying, with brushes, being subsequently painted in the same condition on one or both sides with a water-repellent impregnating material which also makes them pliable. The impregnating material may be composed of chalk, lithopone, a binder consisting of an oil lacquer containing fatty matter and a thinner such as oil

of turpentine or a substitute. The brushing treatment must always be performed in the same direction, in order to make the surface of the paper fabric uniform and flat and to smooth down the fibres which have been raised by the steeping, also to allow of a uniform distribution of the impregnating material.—J. F. B.

Paper fabrics; Process for impregnating —. Gebr. Heyl und Co. A.-G., Charlottenburg. Ger. Pat. 307,771, 14.8.17.

The goods are impregnated with mixtures containing wood tar or wood tar oils and cellulose esters, particularly in combination with amyl acetate. The impregnated fabric may be used as a material for water buckets, tent covers, ground cloths, wagon sheets, etc.—J. F. B.

[*Paper-making machines;*] *Steam inlet and water outlet connections for drying cylinders* [of —]. J. O. Lundberg, Borge, Norway, and H. S. Wahlberg, Sandarne, Sweden. Eng. Pat. 136,485, 25.6.18. (Appl. 15,999/19.)

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Bleaching of cotton fabrics containing coloured threads. R. Aue. Sealed note No. 2117, Aug. 28, 1911. Bull. Soc. Ind. Mulhouse, 1919, 85, 44—45. Report by T. Stricker. *Ibid.*, 45—46.

THE author attributes the bleeding and loss of colour of indigo-dyed threads to the action of the dressings in the material, which exert a reducing action during the alkali boil, and proposes the addition of an oxidising agent to the liquor. Satisfactory results are obtained by the use of sodium peroxide. This method was used in a works at Tagiewa, Baku, in 1909, the kier liquor containing 1½ kilos. of sodium peroxide in 2000 litres of water; boiling was effected at a pressure of 0·3 atm. Further addition of caustic soda is unnecessary; the colour remains unchanged and the whites are well bleached. Stricker points out that the addition of an oxidising agent is not entirely novel, as several methods have been proposed (see Fr. Pat. 392,858 of 1908 and Ger. Pats. 218,254 of 1908 and 250,397 of 1910; this J., 1909, 89; 1910, 419; 1912, 1122). It is pointed out that the addition of sodium peroxide to the lye with ordinary apparatus leads to a serious loss of oxygen.—L. L. L.

Aniline Black; New process for production of — on wool. M. Prud'homme. Sealed note No. 1436, Dec. 30, 1903. Bull. Soc. Ind. Mulhouse, 1919, 85, 39—41. Report by M. Battagay. *Ibid.*, 43—44.

THE author describes an improvement on a process described previously (this J., 1913, 908). The fibre is mordanted and oxidised by means of an acid bath containing 10—20 grms. of chromic acid per litre. The material is steeped for 5—10 minutes, wrung lightly, washed, and then hung up to dry. The dyeing is carried out by working the oxidised material for one hour, or sufficiently long to obtain even impregnation, in a cold bath of aniline and an acid, e.g., hydrochloric acid or an organic acid, preferably formic acid; the material is squeezed and then allowed to lie in heaps. The oxidation is complete in about 1—1½ hours. The material is then simply well washed and dried, further treatment being unnecessary. The use of organic acids prevents too rapid oxidation of the aniline in the bath, and the oxidation is partly obviated by use of a concentrated bath, 100 grms. of aniline per litre. The method is applicable to other bases, e.g., *o*- and *p*-toluidine, benzidine, etc., giving blacks or

browns. It is also applicable to other colouring matters susceptible to oxidation; with these a slight steaming after exposure may be necessary.

—L. L. L.

Aniline Black; Dyeing of — on wool and on mixed wool and cotton, or wool and silk fabrics. M. Prud'homme. Sealed note No. 1454, Mar. 10, 1904. Bull. Soc. Ind. Mulhouse, 1919, 85, 42—43. Report by M. Battagay. *Ibid.*, 43—44.

AN improvement on the process described in the preceding abstract consists in the addition of a ferric salt to the mordanting bath, with or without an acid. The bath contains 1·5 grms. CrO₃, 20 grms. Fe₂Cl₆ of 45° B. (sp. gr. 1·453), 100 grms. of water. The material is steeped for 10 mins. in the cold bath, squeezed, exposed to the air for 10 mins. and washed. It is then dyed by immersing in a cold bath containing 100 grms. of aniline, 80 grms. of hydrochloric acid of 21° B. (sp. gr. 1·17), 100 grms. of formic acid (60%), and 1800 grms. of water, after which it is exposed to the air for 1—1½ hours. Goods containing cotton are preferably mordanted in a bath at 45°—50° C. A considerable improvement is effected by the addition of 0·05—0·1 gm. of potassium permanganate to the iron bichromate bath. For wool alone a passage through a weak formic or oxalic acid bath at 50° C., and with half-wool or "gloria" an acid bath of bichromate, suffices to complete the fixation of the black.

—L. L. L.

Indigo; Direct printing of — on unprepared fabric. L. Caberti, C. Barzaghi, and P. Roggieri. Sealed note No. 1408, July 28, 1903. Bull. Soc. Ind. Mulhouse, 1919, 85, 46—47. Report by T. Baumann. *Ibid.*, 47—48.

THE authors print the material with a paste from which hydrosulphite is formed in the fibre, and thus reduces the indigo. The paste contains gum arabic solution (1/1), 200 grms.; indigo 20% M.L.B., 150 grms.; anhydrous sodium sulphite, 180 grms.; ammonium oxalate, 180 grms.; zinc powder, 60 grms.; soda ash, 50 grms.; borax, 40 grms.; glycerin, 140 grms. After printing the material is dried, steamed for 80—90 secs. at 101° C., and passed through a bichromate bath. Full shades are obtained. The paste appears to give better results after it has been kept for some time. Baumann states that the results are good, and that the colouring matter is entirely reduced to a yellowish green, the colour remaining without alteration for eight days. By double decomposition normal ammonium sulphite is formed in the paste, and this is reduced by the zinc to normal ammonium hydrosulphite.—L. L. L.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Contact sulphuric acid manufacture; Thermal problem in —. F. C. Zeisberg. Trans. Amer. Electrochem. Soc., 1919, 195—202. [Advance proof.]

THE contact process for manufacture of sulphuric acid is outlined with special reference to the control of temperature so as to obtain maximum conversion of the sulphur dioxide. The temperature may be kept below the maximum limit by supplying the reacting gases to the catalyst so slowly that the heat is dissipated by radiation; by diluting the reaction gases with an inert gas; by returning a portion of the converted gases to the entering gas stream and so lowering the concentration; by carrying out the conversion in stages with intermediate cooling of the gases; or by cooling the catalyst and converter by means of pipes and cooling jacket. A résumé is given of many processes embodying the

above principles, all of which, except the re-circulation of a portion of the converted gases, have been used in the past, and a list of U.S. patents is appended.—W. J. W.

Ammonia; Determination of —. Relative accuracy of colorimetric and titrimetric methods. E. R. Allen and B. S. Davisson. *J. Biol. Chem.*, 1919, 40, 183—197.

The volumetric methods are on the whole considered to be the more reliable for general use, although when great care is taken with the experimental technique it is possible that the Nessler process gives results of slightly greater accuracy. Methyl red is undoubtedly the best indicator for the titration of ammonia. (See further, *J. Chem. Soc.*, Feb., 1920.)—J. C. D.

Absorbent for ammonia respirators. G. St. J. Perrott, M. Yablick, and A. C. Fieldner. *J. Ind. Eng. Chem.*, 1919, 11, 1013—1016.

PUMICE-STONE impregnated with copper sulphate is shown to have a large capacity for absorbing ammonia. A canister containing 45 lb. in. of this material will protect a man for at least 5 hrs. in air containing 2% of ammonia, or for 2.5 hrs. in air containing 5% of ammonia. Tests at rapid breathing rates showed that the canister affords ample protection even during severe exertion. Cobalt chloride, ferrous sulphate, silicic acid, and boric acid are also good absorbents of ammonia.

—W. P. S.

Ammonium nitrate; Properties of —. Part I. Freezing point and transition temperatures. R. G. Early and T. M. Lowry. *Chem. Soc. Trans.*, 1919, 115, 1387—1401.

The freezing point of ammonium nitrate is very sensitive to the influence of slight traces of moisture. By careful purification and drying it has been raised to 169.6° C. The two higher transition points were determined from the arrests of temperature on heating and cooling the salt suspended in a liquid of similar density. The mean values found were 125.2° C. and 84.2° C. respectively. The lower transition point was determined dilatometrically and found to be 32.1° C. The arrest points due to the change of state at this temperature do not coincide with the transition point, but are determined by the rate of loss or gain of heat, as the velocity of change of state is much less than at the higher transition points.

—G. F. M.

Nitrogen; Fixation of — in the form of hydrogen cyanide by means of an electric arc. E. Briner and A. Baerfuss. *Helv. Chim. Acta*, 1919, 2, 663—666.

MIXTURES of hydrocarbons and nitrogen, when submitted to the action of an electric arc, produce hydrocyanic acid in yields much superior to the yields of ammonia from nitrogen and hydrogen. The mixture of gases is circulated at a speed of 8—10 litres per hour in a chamber where an arc of 0.020 amp. is burning between platinum electrodes 7 mm. apart. Using a mixture of 12 parts of methane, 23 of nitrogen, and 65 of hydrogen at a pressure of 635 mm., 0.8% by volume of hydrogen cyanide is obtained. This gives a yield of 0.46 grm. HCN per kilowatt-hour in addition to a yield of 0.14 grm. of ammonia per kilowatt-hour. In this case the P.D. applied was 1020 volts. With the same mixture, but with a voltage of 420, 0.12% by volume HCN was obtained, which is 1.75 grm. HCN per kilowatt-hour and 0.44 grm. NH₃ per kilowatt-hour. The best results were obtained with a mixture of 1 part of methane and 5 parts of nitrogen at 505 volts, when a yield of 0.75% by volume of HCN

was obtained, which is 7.39 grms. HCN per kilowatt-hour and 0.48 grm. NH₃ per kilowatt-hour.

—J. F. S.

Chlorine and alkali; Manufacture of — in the United States by modern electrolytic processes. E. Chaleyser. *Rev. Prod. Chim.*, 1919, 22, 613—620.

The various types of electrolytic cells employed for the manufacture of chlorine and alkali are divided into the following classes:—Cells with a permeable diaphragm between the anode and cathode; cells with an intermediate mercury electrode; cells in which stratified layers are formed in the electrolyte; cells employing molten sodium chloride as electrolyte with a lead cathode. The cells with diaphragms are the only ones used to a large extent commercially in the United States, and these may be divided into three groups:—(a) Cells with diaphragms immersed in the electrolyte, with separate arrangements for feeding and circulating the anodic and cathodic electrolytes; (b) cells in which the diaphragm is in contact on the anode side only with the electrolyte, the latter passing from the anode to the cathode compartment; (c) cells with diaphragms immersed in the electrolyte, with circulation of the latter from one compartment to another. In cells containing immersed diaphragms hypochlorites and chlorates are formed, giving rise to oxygen at the anode, with resulting deterioration of anodes and contamination of chlorine by carbon dioxide, together with a low electrolytic yield. The cells of group (b), which include the Townsend, Wheeler, Allen-Moore, and Nelson types, do not suffer from this defect, and are described in detail. The Billiter-Siemens type belongs to group (c),

but is little used in the United States. The Allen-Moore cell is shown in transverse section in the diagram, the dimensions of each cell being: length, 3.4 m.; breadth, 0.55 m.; height, 1.04 m. The electrolyte is freed from calcium, magnesium, sulphate, and suspended organic matter; it contains 310—315 grms. of salt per litre, and is slightly acid (0.01% HCl). The products of electrolysis, chlorine, caustic soda, and hydrogen, are very pure, the purity of the chlorine being 98.6%, and the caustic soda liquor contains 8—10% NaOH and 12% NaCl. For the production of 5 tons of chlorine and 5.6 tons of caustic soda per day of 24 hours, based on a

guaranteed efficiency of 92%, the following figures are given:—

No. of cells.	Ampères.	Volts.	Consumption in K.W.H.	
			Per ton chlorine.	Per ton caustic soda.
150	1200	3.8	3129	2772
130	1400	4.05	3335	2954
120	1500	4.2	3458	3063

The principal advantages claimed for this type of cell are: the cells are constructed of a cheap cement, which is non-conductive and therefore prevents losses of current; dismantling for cleansing and repairing is easily effected, thus avoiding losses of time; a high concentration is obtained in the caustic liquor, reducing expense in evaporation; the life of the anodes is greater than in the cases when hypochlorous acid is formed; practically no chlorate is formed.—B. N.

Alkali chlorides; Comparative electrolysis of —. E. Briner, A. Tykociner, and B. Allmöff. *Helv. Chim. Acta*, 1919, 2, 666—672.

SOLUTIONS of the chlorides of lithium, sodium, and potassium of concentration 3.1N when electrolysed by a current of 50,000 coulombs showed a total current yield of 75%, 82.5%, and 87% respectively. (See also *J. Chem. Soc.*, Feb., 1920).—J. F. S.

Halogens; Indirect electrolytic estimation of —. J. H. Reedy. *J. Amer. Chem. Soc.*, 1919, 41, 1898—1902.

HALOGENS may be estimated electrolytically by the following method. The solution of a halogen salt is electrolysed between a silver gauze anode and a bright platinum cathode with a current of potential 0.59 volt. This ensures the deposition of the whole of the halogen on the anode as silver halide, but towards the end of the process some silver goes into solution. To make sure all the halogen is deposited the current is passed for about 15 mins. at 0.59 volt; at the beginning the current is large, but it falls to a negligible value after this time; the voltage is then raised to 0.60 volt and the current passed for a further 5 mins. The anode is washed, dried, and weighed, and then made the cathode in the electrolysis of a dilute solution of sodium hydroxide until there is a free evolution of hydrogen. This reduces the silver halide to black silver, which is not very adherent and must be handled carefully. The electrode is washed, dried, and heated in an electric furnace until it becomes white and the whole is sintered together. It is then weighed, and the loss in weight gives the weight of the halogen. The method gives results comparable in accuracy with those obtained by the usual gravimetric method.—J. F. S.

Perchlorate; Electrolytic formation of — from chlorate. J. G. Williams. *Faraday Soc.*, Dec., 1919. [Advance copy.]

THE formation of perchlorate by electrolysis is considerably improved if a higher temperature (up to 60° C.) is maintained in the electrolyte, and the frequent addition of acid still further improves the efficiency. During the electrolysis chloride is produced, and there appears to be an equilibrium value for each temperature, varying from 2.3 grms. per litre at 31° C. to 4.7 grms. per litre of sodium chloride at 59° C.—B. N.

Potassium permanganate; Manufacture of — from ferro-manganese by electrolysis. M. de K. Thompson. *Chem. and Met. Eng.*, 1919, 21, 680—681.

THE commercial manufacture of potassium permanganate from ferro-manganese was investigated. A preliminary small-scale experiment was carried

out with ferro-manganese of the following composition:—Mn, 75.1%; Fe, 16.7%; C, 6.1%; Si, 0.9%; P, 0.2%; Cu, Ni, Ca, Mg, As, traces. Using potassium hydroxide solution (24 grms. per 100 c.c.) with an anode current density of 180 amp. per sq. ft. at 45°—50° C., electrolysis proceeded for a few hours with a current efficiency of 15%, but the anode became coated with oxides. This trouble was obviated by substituting an electrolyte of 20% potassium carbonate solution. A large-scale experiment which was carried out showed the necessity of keeping the temperature of the electrolyte down to 40° C. to prevent coating of the anode. Sheet-iron cathodes and asbestos cloth diaphragms were used. Current density was 65 amp. per sq. ft. at 4.2 volts, with total current of 350 amp., and current efficiency was about 17%. The electrolytic concentration was 200 grms. per litre. The process was continued for five days, but arrested each night. The liquid and anode mud were then removed and heated to 90° C., and the solution filtered and crystallised, the crystals being finally centrifuged. About 40 lb. of 98% potassium permanganate was made. The estimated cost was \$0.38 per lb. The process is stated to be commercially feasible.—W. J. W.

Potash; Wood ashes and production of —. E. Bateman. *Chem. and Met. Eng.*, 1919, 21, 615—619.

THE ash content of American species of wood varies from 0.05 to 3.02% in hardwoods, and from 0.02 to 0.82% in softwoods, with an average of 0.61% and 0.30% respectively, but the content of the same species may vary within wide limits. Most of the ash from softwoods is lost in burning, being carried up the chimney. The potash content of pure wood ashes is considerably higher than that of commercial ashes which contain sand, sawdust, charcoal, and other impurities. A large number of analyses of commercial ashes gave an average of 3.6% K₂O. The potash is recovered from the ashes by leaching. The author describes the plant and its operation and gives details of the manufacturing costs. During normal times the manufacture of potash from wood ashes would not be remunerative except under specially favourable local conditions.

—S. S. A.

Silicate of soda; Properties of commercial —. J. G. Vail. *J. Ind. Eng. Chem.*, 1919, 11, 1029—1031.

ALL commercial preparations of sodium silicate contain more silica than corresponds to the formula Na₂SiO₃, one grade containing four times that amount. The ratio between sodium oxide and silica varies between 1:4 and 2:3. Products more alkaline than the latter are not made owing to their tendency to crystallise, whilst the limit in the other direction is fixed by the low solubility of preparations containing more silica. The green or yellow colour of the commercial products is due to small amounts of ferrous or ferric iron, the latter being most frequent in the alkaline types. The solution with 1:4 ratio may be concentrated to about 37° B. (sp. gr. 1.305; about 34% of total solids) and then has the consistence of a jelly; if cooled to 5° C. it may be moulded into balls. A silicate of 2:3 ratio may be concentrated to about 69° B. (sp. gr. 1.916; about 62.5% total solids), and is then a tough mass which may be drawn into threads; it absorbs moisture from the air. The possible concentration increases with the rise in the alkali content. The ordinary 40° silicates freeze at about -3° C., becoming white and opaque, whilst solutions of above 60° B. (sp. gr. 1.71) do not lose their transparency on freezing, but become harder and finally brittle. The precipitates formed in sodium silicate solutions by most salts of heavy metals are said to contain free silicic

acid. Precipitation is also effected by various dehydrating agents, such as alcohol, glycerin, salt brine, and strong ammonia solution. The precipitates may be re-dissolved, but the resulting solutions differ from the original solution, notably, in their viscosity. Solutions rich in silica increase slowly in viscosity until the condition of jelly is reached, when there is a very pronounced increase. This is the case whether the rise in viscosity is due to decrease in alkalinity, decrease in temperature, or increase in concentration. Advantage is taken of this property in preparing rapid-setting adhesives from sodium silicate. The change from a liquid to a solid condition may take place with the loss of 1% of moisture, which may be rapidly absorbed by a layer of paper-board. Solutions suitable for this purpose when dried in the air do not contain less than about 20% of moisture. The resulting solid solution is more soluble than anhydrous silicate of the same relative composition. If suddenly exposed to a temperature above 100° C. such a solution expands into a mass of permanent bubbles, and has an apparent sp. gr. as low as 0.01. In this condition it is an excellent thermal insulator. Gels of widely different physical characters are made by treating silicate solutions with varying concentrations of acid. Strongly acid gels are used to prevent the splashing of acid from storage batteries, whilst very hard neutral gels may be used in the preparation of material for the adsorption of gases. The tensile strength of sodium silicate mixtures for acid-proof cements is easily brought up to 1700 lb. per sq. in. for air-dried briquettes, whilst a baked mixture of sodium silicate and clay, as used in the manufacture of abrasive wheels, has a tensile strength above 2000 lb. per sq. in.—C. A. M.

Ammonium chloride; Transition of dry —. A. Smith, H. Eastlack, and G. Scatchard. J. Amer. Chem. Soc., 1919, 41, 1961—1969.

AMMONIUM chloride dried over phosphorus pentoxide in a vacuum for three years at ordinary temperatures or for 45 days at 155°—165° C. undergoes the same transition to a second crystalline form at 184.5° C. (See also J. Chem. Soc., Feb. 1920.)—J. F. S.

Precipitates; New physico-chemical method of analysis of —. Application to the study of the calcium phosphates. P. Jolibois. Comptes rend., 1919, 169, 1161—1163.

Using the rapid method for mixing solutions previously described (this J., 1920, 81a), the author has studied the products obtained by mixing solutions of calcium hydroxide and phosphoric acid in varying proportions. In each case when equilibrium was reached the precipitate was collected and analysed and the supernatant liquid was analysed. Dicalcium phosphate can only be formed in a solution containing at least 0.80 gm. P_2O_5 per litre in the form of monocalcium phosphate, and similarly tricalcium phosphate is only stable in a solution containing less than 0.1 gm. P_2O_5 per litre. A new phosphate, $Ca_2P_2O_7 \cdot Ca_3(PO_4)_2 \cdot 10H_2O$, was obtained in a crystalline form.—W. G.

Stannous chloride; Decomposition of — by water and potassium hydroxide solutions. C. M. Carson. J. Amer. Chem. Soc., 1919, 41, 1969—1977.

THE compound, $2SnCl_2 \cdot 7Sn(OH)_2$, is the most basic of all the basic stannous chlorides. The slightly variable crystalline material formed by the action of boiling potassium hydroxide on stannous chloride has the composition, $3SnCl_2 \cdot 5SnO \cdot 3H_2O$. (See also J. Chem. Soc., Feb., 1920.)—J. F. S.

Chromic sulphate; A new complex form of —. A. Recoura. Comptes rend., 1919, 169, 1163—1166. A NEW complex chromic sulphate, in which the

whole of the sulphate is masked, has been prepared as follows. A $N/2$ solution of chromic sulphate was allowed to stand until equilibrium was reached as far as the formation of the green sulphate is concerned, and then the solution was evaporated to saturation point in a vacuum. Excess of alcohol was added and the lilac-grey precipitate obtained was immediately collected, washed with ether, and allowed to dry. So prepared it contained $18H_2O$, and the whole of its SO_4 was precipitable by barium chloride. On exposure to air it rapidly and spontaneously changed, and at the end of two days, whilst retaining its colour, only contained $16H_2O$ and no longer gave a precipitate with barium chloride. When left in a desiccator its water content dropped to $12H_2O$.—W. G.

Lead dioxide; Colorimetric determination of — in litharge. W. V. Morgan. J. Ind. Eng. Chem., 1919, 11, 1055.

FIVE grms. of the litharge is boiled for 1 min. with 2 grms. of aniline hydrochloride dissolved in 10 c.c. of water and 5 c.c. of concentrated hydrochloric acid; the mixture is then cooled, filtered, and the colour of the filtrate compared with standards prepared with known amounts of lead peroxide under the same conditions. The lead peroxide oxidises the aniline with the formation of Aniline Purple, and the intensity of the coloration is proportional to the amount of peroxide.—W. P. S.

Lead peroxide; Reguline —. W. Palmaer. Med. K. Vetensk. Nobelinst., 1919, 5, No. 31, 1—15.

COMPACT lead dioxide is prepared by the electrolysis of lead nitrate solution. The product is greyish-black and has a crystalline appearance. It contains no impurities, has hardness 5—6, sp. gr. 9.360. It is similar to the mineral plattnerite. The specific resistance at 18° C. is 0.000815 ohm, and the specific conductivity 1180 ohm⁻¹.—J. F. S.

Hydrogen peroxide; Catalytic decomposition of —. G. Phragmén. Med. K. Vetensk. Nobelinst., 1919, 5, No. 22, 1—13.

IN phosphate mixtures the catalysis of hydrogen peroxide reaches a maximum at $pH=11.8$. The velocity decreases with both increasing and decreasing hydrogen ion concentration. This is due to the formation of a stable sodium salt of hydrogen peroxide in strong alkaline solutions. Fresh yeast decomposes hydrogen peroxide without sending a soluble enzyme into the surrounding solution. The reaction is of the first order, and the reaction constant is proportional to the quantity of yeast. The catalytic action per cell or per gm. can be increased by treating the yeast with sugar solution before use.—J. F. S.

Mercury compounds; Microchemical identification of soluble and insoluble —. G. Denigès. Bull. Soc. Pharm. Bordeaux, 1919, No. 2. Ann. Chim. Analyt., 1919, 1, 383—385.

CHARACTERISTIC crystals are formed when a small quantity of a mercury compound or salt is treated on a microscope slide with a drop of potassium iodide-bromide solution. Mercurous compounds and mercuric cyanide are treated previously with bromine-water. In the case of mercuric iodide, the crystals obtained on evaporating its alcohol or acetone solution serve for the identification. —W. P. S.

Protactinium; Chemical properties of —. Part I. Separation of protactinium from pitchblende. O. Hahn and L. Meitner. Ber., 1919, 52, 1812—1828.

PROTACTINIUM was separated from the other radioactive substances in pitchblende by three different

methods based on the assumption, thereby proved correct, that this new radioactive element belongs to the tantalum group. Since by all methods the yields of protactinium as measured by the activity of the final residues per grm. of pitchblende only varied by about 10%, it was concluded that within this limit the element had been quantitatively separated long with the added tantalum. The activity of the protactinium residue, however, was much lower than would be expected relative to the activity of the uranium associated with it in the pitchblende if the proportion of uranium atoms disintegrating into the actinium series was as much as 8%, as given by Rutherford. A value of 3% seems more in accord with the facts, and is, moreover, in better agreement with the value found by Antonoff (Phil. Mag., 1913, 26, 1058) in the case of uranium Y, the immediate parent of protactinium. The question whether it may be possible to separate protactinium as a new chemical individual depends largely on the at present uncertain life of the element. A lower limit for this could probably be found by an investigation of uranium salts of known age, say 25 or 50 years old, for their protactinium content.—G. F. M.

Sulphur; Method of dissolving elementary — for analysis. A. P. Bierregaard. J. Ind. Eng. Chem., 1919, 11, 1055.

ABOUT 0.1 grm. of the sulphur is dissolved in dry bromine, 10 c.c. of concentrated nitric acid is added, and the mixture is warmed. After removing excess of bromine and nitrous fumes by continuing the heating, the solution is diluted with 100 c.c. of water, a few c.c. of hydrochloric acid is added, and the solution boiled to expel the remainder of the nitric acid. The sulphuric acid is then precipitated with barium chloride.—W. P. S.

PATENTS.

Nitric acid and tetroxide of nitrogen [from nitric acid containing oxides of nitrogen]; Process of producing pure concentrated —. O. Jensen, Assignor to Norsk Hydro-Elektrisk Kvaestof-aktieselskab, Christiania, Norway. U.S. Pat. 1,324,255, 9.12.19. Appl., 4.2.19.

THE acid to be purified is passed in counter current to nitric acid vapour, and the nitrogen tetroxide expelled is condensed. The remaining acid is subjected to distillation and dephlegmation to produce dilute, liquid acid and vapour of highly-concentrated acid, a portion of the latter being condensed and the remainder employed for treating a further quantity of the impure acid.—W. E. F. P.

Ammonia; Apparatus for the synthetic production of —. General Chemical Co., Assignees of F. W. de Jahn, New York. Eng. Pat. 124,762, 28.2.18. (Appl. 7872/19.) Int. Conv., 3.11.17.

AN apparatus for the conversion of mixed hydrogen and nitrogen gases into ammonia consists of a pressure system comprising a cylindrical metal shell screw-threaded at each end, with apertured top and bottom covers each held in place by an annular screw plug engaging with the thread on the shell and provided with plates for the apertures, bolted to the covers, combined with a heat interchanger comprising a shell enclosing a series, at least three in number, of concentric tubes, gas passages for the gases flowing in opposite directions being formed between the walls of the tubes.—S. S. A.

Ammonia; Purification of —. C. L. Parsons, Washington, D.C., and L. C. Jones, Syracuse, N.Y., U.S.A. Eng. Pat. 136,342, 20.1.19. (Appl. 1442/19.)

AMMONIA is freed from phosphine by treating it at 50°–60° C. with air in the presence of a catalyst comprising carbon or a carbonaceous substance coated or impregnated with a metal or metallic compound, preferably of the silver group, reduced or partially reduced by ignition in an atmosphere of hydrogen. The catalyst, packed in removable containers, is placed in a series of chambers which are operated alternately in parallel and are provided with steam jackets whereby the desired temperature is obtained to expel ammonia after the oxidation of the phosphine. The ammonium phosphate produced during the process is held by the catalyst, and when the catalyst becomes clogged the ammonia is expelled and recovered by heating the chamber jacket and blowing through the catalyst steam and air heated in pipes passing through the jacket. The carbon is revived by thorough washing and drying.—S. S. A.

Ammonia; Method of extracting — [from crude ammoniacal liquor]. E. Piron, New York. U.S. Pat. 1,324,979, 16.12.19. Appl., 20.7.18.

CRUDE ammoniacal liquor is mixed with alkali solution at atmospheric temperature, and the mixture is passed continuously into the bottom of a decanting vessel. The clear liquor passes continuously into a still for extraction of the ammonia, and the solid matter which settles in the bottom of the decanting vessel is withdrawn from time to time.—L. A. C.

Alumina poor in iron; Process for producing —. Det Norske Aktieselskab for Elektrokemisk Ind. Norsk Industri-Hypotekbank, Christiania, Norway. Eng. Pat. 125,578, 24.12.18. (Appl. 21,659/18.) Int. Conv., 8.4.18.

LABRADORITE or a similar mineral is treated with nitric acid on the counter current principle to obtain a neutral solution to which, after filtration from insoluble matter, a basic precipitant, e.g., alumina, is added, thereby precipitating iron and silica which are removed. The solution is evaporated and the residue is calcined at about 300° C. by means of hot gases from a nitric acid plant in the absorption tower of which the nitrous gases produced by the resulting decomposition of the aluminium nitrate are recovered. The undecomposed calcium and sodium nitrates are separated from the alumina by lixiviation and recovered by evaporation for use as fertilisers.—S. S. A.

Alumina [from alkaline solutions containing silica]; Process of recovering —. G. G. Miner, Berkeley, Assignor to The Miner Chemical Corporation, San Francisco, Cal. U.S. Pat. 1,324,318, 9.12.19. Appl., 19.12.17.

ALUMINA and silica are precipitated separately by carbonating the alkaline solution at successively higher and lower temperatures.—W. E. F. P.

Alkali sulphides [and iron]; Method for the production of —. E. Bergve, Notodden, Norway. Eng. Pat. 129,629, 13.6.19. (Appl. 14,950/19.) Int. Conv., 8.7.18.

A SUITABLE mineral is fused in a shaft furnace at a temperature of about 1250° C. with a mixture of pyrites and silicon in the form of ferro-silicon. The resulting products separate into layers, iron at the bottom and alkali sulphides at the top, which can be drawn off through suitably placed tap-holes.—S. S. A.

Cyanides; Manufacture of —. F. J. Metzger, Assignor to Air Reduction Co. U.S. Pat. 1,322,195, 18.11.19. Appl., 7.3.19.

ALKALI cyanide is produced by heating to a suitable temperature a mixture of carbonaceous material, alkali metal compound, and finely-divided iron, in presence of nitrogen, the amount of iron being so small that no appreciable quantity of ferrocyanide is formed when the furnace product is leached with an aqueous solvent.—J. H. L.

Alkali metal cyanides; Production of —. C. B. Jacobs, Bloomfield, N.J., Assignor to Air Reduction Co. U.S. Pat. 1,321,119, 9.12.19. Appl., 19.12.16.

AN alkaline-earth carbide is heated with an excess of carbon and an alkali metal compound, and the heated mass is subjected to the action of nitrogen.—S. S. A.

Sodium fluoride; Method of producing —. F. C. Bowman, Assignor to General Chemical Co., New York. U.S. Pat. 1,324,030, 9.12.19. Appl., 9.3.18.

A suspension of sodium fluosilicate is treated with soda at such a rate that the mixture remains acid or neutral.—S. S. A.

Lead arsenate; Method of making —. M. W. Butler, Assignor to The Harshaw, Fuller, and Goodwin Co., Cleveland, Ohio. U.S. Pat. 1,324,300, 9.12.19. Appl., 8.12.17.

THE lead compound obtained as a by-product in the preparation of sodium nitrite, by heating sodium nitrate with metallic lead, is treated with arsenic acid.—W. E. F. P.

Soluble salts from flue-gases; Apparatus for collecting and isolating —. L. D. Gilbert, P. S. Taylor, J. G. Dean, and L. E. Elder, Victorville, Cal. U.S. Pat. 1,324,737, 9.12.19. Appl., 25.6.17.

IN an apparatus for recovering soluble salts in suspension in superheated steam the latter is passed into a condensing chamber, and the condensed liquid is passed through a filter into an evaporating chamber maintained under reduced pressure, the two chambers being separated by a wall through which heat is readily transmitted. Means are provided for withdrawing a portion of the liquid from the evaporating chamber, for cooling the portion so withdrawn to effect crystallisation of the soluble salts, and for returning the mother liquor to the evaporating chamber.—W. E. F. P.

Manganese peroxide; Process of obtaining —. E. H. Westling, Antioch, Cal. U.S. Pat. 1,325,129, 16.12.19. Appl., 14.3.18.

A STEEL in the production of manganese peroxide consists in treating a mixture of manganese oxide ore and a liquid with hot sulphurous acid, thus producing a solution of manganese sulphate.—B. M. V.

Phosphine; Process of oxidising — and apparatus therefor. J. D. Davis, Washington, D.C. U.S. Pat. 1,325,145, 16.12.19. Appl., 19.8.18.

A GASEOUS mixture containing phosphine and oxygen is brought into contact with a catalyst capable of oxidising phosphine selectively and contained in a steam-jacketed chamber. The steam jacket is traversed by tubes which communicate at one end with the space containing the catalyst, and at the other end with a supply of compressed air.—W. E. F. P.

Aluminium chloride; Process of manufacturing —. J. R. Mardick, New York. U.S. Pat. 1,325,203, 16.12.19. Appl., 12.3.19.

AN aluminium compound or ore is heated with

carbon bisulphide and chlorine at such a temperature that aluminium chloride is evolved.—B. V. S.

Sulphur dioxide; Preparation of — from magnesium sulphate or double salts of magnesium. Chemische Fabr. Rhénania, Stolberg. Ger. Pat. 300,716, 26.5.16.

HYDROGEN sulphide is passed over magnesium sulphate heated to redness, the magnesium sulphate being kept in excess throughout the process by moving it in an opposite direction to the gas. If the hydrogen sulphide is pure the sulphur dioxide produced will be free from impurities and can be easily condensed, but it may be contaminated with nitrogen if the hydrogen sulphide is derived from the Chance process. If double salts of magnesium and alkalis are used these are converted into sulphides, which may be freed from magnesium oxide by treatment with water and converted into carbonates by means of carbon dioxide.—W. J. W.

Sulphur dioxide; Method of removing — from gases by thionate solution. W. Feld, Gasabteilung, G.m.b.H., Linz. Ger. Pat. 314,627, 27.8.18.

THE gases are washed with a solution of ammonia, and the resulting solution of sulphite or bisulphite is treated with tetrathionate to produce thiosulphate. Aqueous solutions of alkaline ammonium salts may be used for washing the gases. Instead of tetrathionate a solution of tetrathionate with other thionates may be employed. The treatment of the sulphite with thionate may be carried out continuously or intermittently.—W. J. W.

Oxides of sulphur; Manufacture of —. Badische Anilin- u. Sodafabrik, Ludwigshafen. Ger. Pat. 300,763, 20.4.15.

FINELY-POWDERED wood charcoal, lignite, or coke is mixed with magnesium sulphate in the proportion of one atom of carbon per molecule of magnesium sulphate. To bring about an intimate admixture of the two ingredients a solution of magnesium sulphate may be used. The mixture is heated to about 600°–700° C., decomposition commencing at a dull red heat. The process yields magnesium oxide and sulphur dioxide without simultaneous formation of magnesium sulphide.—W. J. W.

Aluminium sulphate; Production of an iron-free solution of — from clay. Papierfabrik Köslin A.-G., Köslin. Ger. Pat. 301,614, 28.9.16.

CLAY is treated with an alkali bisulphate in presence of an oxidising agent such as barium peroxide, the mixture being heated to 300°–400° C. for a long period. Iron compounds are thus converted into basic iron sulphate, which is insoluble in water or alum solutions.—W. J. W.

Zinc sodium sulphate; Preparation of —. Farbenfabriken vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 301,782, 20.2.17.

A DOUBLE sulphate of zinc and sodium which may be used instead of zinc sulphate is prepared by treatment of solutions, containing both sulphates, with a bisulphate; or substances containing zinc may be dissolved in a solution of sodium bisulphate, and the zinc sodium sulphate separated from the solution by addition of bisulphate.—W. J. W.

Zinc compounds; Preparation of pure — from impure materials. Farbenfabriken vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 303,802, 20.2.17.

THE method described in Ger. Pat. 301,782 (see preceding abstract) may be applied to the recovery of zinc from zinc-containing compounds such as pyrites waste, zinc oxide, etc.—W. J. W.

Alkali carbonates; Process for manufacture of —. E. Hene, Stassfurt, and A. van Haaren, Leopoldshall. Ger. Pat. 302,535, 17.11.16.

MONOALKALI cyanamide is decomposed by water at a temperature above 100° C., or better, above 120° C. The cyanamide is first freed from calcium compounds by addition of a carbonate. The decomposition may take place under pressure. The products obtained are an alkali carbonate and ammonia together with carbon dioxide. The solution is treated with a caustic alkali and the ammonia is driven off. It may alternatively be strongly heated and the expelled gases allowed to react with bases.

—W. J. W.

Iodine; Process of purifying —. R. M. Carter, Baltimore, Md., Assignor to U.S. Industrial Alcohol Co. U.S. Pat. 1,324,761, 9.12.19. Appl., 24.12.18.

IODINE containing iodine compounds as impurities is subjected to the action of a heated gaseous medium, by which means the iodine is separated from the impurities and vaporised.—W. J. W.

Sulphur; Process for manufacture of —. Harburger Chem. Werke Schön und Co., and W. Daitz, Harburg. Ger. Pat. 303,233, 29.9.16.

SULPHUR dioxide and hydrogen sulphide enter the top and bottom respectively of a reaction chamber and interact in presence of steam. Escape of undecomposed hydrogen sulphide is prevented by employing a tower-shaped chamber having the upper portion divided into compartments placed one above another and connected by pipes. Salt solution may be sprayed into the chamber. The sulphur is readily obtained in the form of grains. The process is conveniently employed in connection with the manufacture of sulphuric acid, and the hydrogen sulphide may be obtained from the calcium sulphide derived from the Leblanc soda process.—W. J. W.

Ammonia; Process for effecting fixation of atmospheric nitrogen and production of —. E. W. Haslup, New York. Eng. Pat. 135,889, 24.10.18. (Appl. 17,364/18.)

SEE U.S. Pats. 1,310,478–9 of 1919; this J., 1919, 629 A. (Reference has been directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 4037 and 16,760 of 1893, 18,792 of 1894, and 10,305 of 1907; this J., 1894, 517, 886; 1895, 967; 1908, 1052.)

VIII.—GLASS; CERAMICS.

Thermo-couple installation in annealing kilns for optical glass. E. D. Williamson and H. S. Roberts. Papers on Optical Glass, No. 15. Geophysical Lab., Washington. Bull. No. 152, Amer. Inst. Min. and Met. Eng., Aug., 1919, 1445–1453.

IN the annealing of optical glass, temperatures up to 650° C. have to be measured correct to within 5° C. The necessity for careful regulation of temperature during the beginning of cooling demands the use of a temperature-measuring device, of which the sensitivity is well within 5° C. A pyrometer installation for use with an installation of annealing kilns comprising eleven kilns in one room, twenty in a second, and four in a third is described. The couples employed were constituted of chromel-alumel, and were used in conjunction either with a potentiometer or a modification thereof of the pyrovolt type. The system of wiring, whereby all temperatures could be read at one central station, is detailed. The system is such that the leads from the constant temperature junctions and the leads from the variable temperature

junctions are led to terminals enclosed in a box, so that all these terminals are at the same temperature. Copper leads are employed to connect these terminals with the potentiometer. It appears that best results in the annealing of optical glass are secured if the glass is maintained for six hours at the temperature at which the strain disappears and is thereafter cooled at a rate that is rapidly increased as the temperature falls. The temperature should be taken at more than one point in a kiln. No difficulty was experienced in training men to take the readings properly, and errors in reading were eliminated entirely.

—J. S. G. T.

Red glass; Production of selenium —. F. A. Kirkpatrick and G. G. Roberts. J. Amer. Ceram. Soc., 1919, 2, 895–904.

IN producing selenium red glass the details of the working appear to be almost as important as the composition of the glass, but when the correct conditions are obtained selenium is more reliable than copper and cheaper than gold. Two kinds of glass were made: a soft-working zinc-alkali glass (sand 53.70, potash 16.25, soda ash 16.25, zinc oxide 11.37, and cadmium sulphide, selenium, and borax each 0.81%), and plate glass (sand 62.60, soda ash 18.60, hydrated lime 17.30, cadmium sulphide 0.85, and selenium 0.65%). The materials were mixed in 30 lb. batches and introduced in three portions into a closed "monkey pot," which had previously been heated to 1400° C. After three hours the glass was allowed to fine for five hours, and after a further three hours the pot, with its contents, was allowed to cool slowly until ready for use. Shortly before withdrawing any glass the molten material should be skimmed, the "scum" being used as cullet in the next melt. During the melting and fining periods the pot must be kept closed to prevent the escape of selenium vapour. Portions of the zinc glass were withdrawn at 680° C. on a blowpipe and gathered, rolled, pressed in a mould, allowed to cool, flashed in the glory hole, allowed to cool, and then placed in thelehr, the whole of these operations occupying 130 secs.; the portions withdrawn from thelehr after 36 hours were all deep red in colour. Portions of the plate glass were gathered, cooled to 400° C., flashed, pressed in the mould, and then put in thelehr, the whole of these operations occupying 110 secs, but these times may not apply to larger batches. Cooling to 400°–700° C. immediately after gathering appears to be essential to the production of a red colour; in the case of blown ware the cooling may occur during the blowing, but the glass must not be reheated until it has been cooled sufficiently. After this reheating has no effect. The ware blown in moulds sometimes did not develop its colour until after it had been placed in thelehr.—A. B. S.

Clays; Relations between the chemical composition, microscopic structure, and ceramic qualities of —. L. Bertrand and A. Languine. Comptes rend., 1919, 169, 1171–1174.

THE petrographic study of a large number of samples of clays shows that the view, often held and used in the interpretation of the results of chemical analysis, that the alkalis present are in the form of mica is incorrect and must be abandoned. Micaceous plates were found only very exceptionally. In respect to the classification of clays as "fat" or "lean," the authors find that there is no rigorous relationship between the character of a clay in this respect and its relative proportions of silica and alumina. Certain clays rich in silica are abnormally "fat," owing to the fact that their free silica is in a colloidal state or else in the form of extremely fine quartz grains. Similarly, many exceptions were found to the rule that the higher the

alumina content the more refractory is the clay. The chemical composition of a clay does not suffice as a criterion of its ceramic qualities.—W. G.

Refractories Manufacturers' Association; Work of the technical division of —. [Manufacture of firebrick.] R. M. Howe. J. Ind. Eng. Chem., 1919, 11, 1145—1146.

THE composition and properties of clay deposits vary greatly, and the miner should be able to accept or reject at sight each piece as it is obtained. A systematic investigation has shown that some of the best clays are often rejected through ignorance. The proportion of water used in preparing the clay paste affects the porosity and modulus of rupture of the burned product. The greater the proportion of water (within working limits) the less the porosity and the greater the strength of the burned product. An excess of water reduces the strength, but does not affect the density so much as an insufficiency. Prolongation of the pugging also increases the strength. Slow drying is more effective than rapid drying in reducing shrinkage, in preventing the "creeping" of arches and "opening" of joints, and in producing a firm bond and resistance to abrasion. Studies of the porosity-burning temperature graphs of clays give useful information as to the heat-treatment necessary to obtain a good product and indicate to the user how different clays are likely to behave in service, i.e., whether they will remain open or become dense. The investigations show that every step in the manufacture of firebricks is important, and that this industry is not so crude as is often supposed.

—A. B. S.

Refractories for industrial furnaces; Selection of —. W. F. Rochow. J. Ind. Eng. Chem., 1919, 11, 1146—1149.

A SUPERFICIAL consideration of the chemical and physical properties of a refractory material is not sufficient and is often misleading, as good results are sometimes obtained from products, the chemical composition and physical properties of which appear to make them unsuitable; thus silica bricks have been used for many years for lining kilns used for burning magnesite and in the roofs of tanks and pots for melting glass, although they are subjected to alkaline vapours from the glass batch. *Silica bricks.*—The most important properties of silica bricks are their high thermal conductivity, mechanical strength, resistance to abrasion at furnace temperatures, expansion when heated, tendency to spall, and refractoriness. Their good conductivity is specially useful in coke-ovens and muffle-furnaces. Spalling may be reduced and often eliminated by heating and cooling slowly through the critical range at which most of the expansion occurs (below 500° C.). Unlike fireclay and magnesia refractories, there is only a small difference between the softening and melting points of silica, so that deformation does not occur until the latter is almost reached. Hence in arches silica bricks with a covering of kieselguhr or other insulator are efficient where fireclay bricks would soften gradually and collapse. The temperature at which bricks are deformed when heated under a pressure of 25 lb. per square inch is a good indication of their usefulness. The sp. gr. is a criterion of the extent to which the permanent expansion should be carried at the first firing, 238 being suggested as the upper limit for a well-burned American silica brick. An examination of the various zones in a used firebrick often shows the manner in which deterioration occurs. *Magnesite bricks.*—American magnesite—unlike the Austrian material—is deficient in iron, but the addition of 4.5–8% of ferric oxide widens the range of vitrification and develops good bonding properties at furnace temperatures and other properties similar to

those of Austrian magnesite. At high temperatures magnesite bricks are mechanically weak and have a feeble resistance to abrasion. When magnesite is heated it expands considerably, the maximum expansion occurring at 1350° C.; on this account bricks tend to spall when cooled too rapidly. In several cases—especially in back walls, bulkheads, and gas-ports of basic open-hearth furnaces, and in the side walls of electric steel furnaces—soft steel boxes filled with compressed dead-burned magnesia are preferable to magnesite bricks. The exposed face of the steel container melts and impregnates the magnesia forming a jointless surface with very small tendency to spall. Specially shaped refractory blocks and bricks should be avoided wherever possible, as they are more liable to defects in workmanship than the standard shapes.

—A. B. S.

Refractories in the iron and steel industries. C. E. Nesbitt and M. L. Bell. J. Ind. Eng. Chem., 1919, 11, 1149—1151.

THE most important working qualities of silica bricks can be determined by spalling and hot crushing tests, and those of fireclay bricks by these two tests and a slagging test. Silica bricks show a fall in crushing strength when heated to 1350° C. Fire-cracks also reduce the durability of bricks exposed to great thermal changes. Roofs of open-hearth furnaces should last for 200 heats, and they then have a spalling loss of about 20%. In a recent shipment of clay chequer bricks the average spalling loss was 1.4% for normal bricks and 60% for hard-burned ones. The finer the material of which silica bricks are made, the greater the spalling loss and the shorter the "life" in the furnace. Variation in the quality of refractory bricks is also shown by measuring the depths of penetration of a steel ball under a pressure of 1600 lb. at 1350° C. and by an impact test in which a steel ball weighing 21 lb. is dropped on the heated brick from heights increasing successively by 2 in.—A. B. S.

Refractories; Superior —. R. C. Purdy. J. Ind. Eng. Chem., 1919, 11, 1151—1153.

THE limiting factor in the development of electric furnaces is the lack of adequate refractories. Refractories of superior quality are also required for high-tension insulators and for the manufacture of new alloys and glasses. Although special materials, such as pure silicon carbide, fused alumina, sintered magnesia, fused spinels, crystallised sillimanite, calcined zirconia, etc., will be used, most of the new requirements will be met by intelligent adaptation of materials in general use, probably by fusing them so that they attain complete chemical stability and constancy in volume. The ordinary classification of refractories as neutral, basic, or acid has little value except for steel-making, and a few slag tests will show that the corrosive effect of a slag is the same on either basic or acid refractories. There is no need to have a neutral course between basic and acid bricks in a furnace.

Sheet steel and iron; Cleaning — for enamelling purposes. R. R. Danielson. J. Amer. Ceram. Soc., 1919, 2, 883—894.

IN addition to the customary methods of cleaning sheet steel and iron by scaling and then pickling in acid solutions, the author advocates other methods, including the use of chemical grease-removers, such as a boiling solution of sodium hydroxide or carbonate, especially with the aid of an electric current. Naphtha and gasoline are not suitable for the removal of grease from sheet metal prior to enamelling, as they leave a thin film of grease on the metal. For heavy sheets, sand-blasting is effective but not for light-gauge sheets and special shapes. Electrolytic pickling in dilute sul-

phuric acid is quicker and cheaper than simple acid pickling, and the effect is more uniform. In all cases any acid used should be removed in a neutralising bath consisting of a 0.4% solution of soda ash or preferably a mixture of 12 lb. of caustic soda, 6 lb. of soda ash, and 400 galls. of water. Immediately after withdrawal from this bath the metal should be rinsed in water and dried by artificial heat at 150°–230° F. (55°–110° C.), a current of clean air being preferable to the use of steam coils, as the latter do not always dry the ware thoroughly.

IX.—BUILDING MATERIALS.

Concrete; Effect of vibration, jiggling, and pressure on fresh —. D. A. Abrams. *Structural Materials Research Lab., Lewis Inst., Chicago, Ill.* 3. Reprint from Proc. Amer. Concrete Inst., 1919, 15. 23 pages.

TESTS showed that tamping, vibration, and jiggling are of value in forcing the concrete into its place in intricate moulds or where reinforcement is used, but when applied after the completion of the moulding such treatment does harm. Tamped concretes were usually weaker than those which were hand-puddled, a large tamper being less effective than a smaller one. The advantages derived from tamping, vibrating, or jiggling during moulding are that the concrete is placed more certainly in position and is finished dryer; any excess of water is brought to the surface and should then be removed, and coarser aggregate may be used and therefore a less proportion of water employed. When the concrete has begun to set tamping, vibration, or jiggling will notably reduce its strength.—A. B. S.

Marbles of the U.S.A.; Physical and chemical tests on the commercial —. D. W. Kessler. U.S. Bureau of Standards, Tech. Paper, No. 123, 15.7.19. 54 pages.

FIFTY average samples of American marble were tested for crushing and tensile strength, resistance to freezing, absorption, specific gravity, porosity, staining, permeability, expansion, and electrical resistivity. The average crushing strength of cubes of white marble of uniform texture was 9174 lb. per sq. in., that of prisms of the same material and cross-sectional area was 7828 lb. per sq. in. Prisms and cylinders of the same height had approximately the same crushing strength. Other marbles varied from 7850 to 50,205 lb. per sq. in., the dolomites being stronger than the calcite marbles. When the test-pieces were wet the crushing strength was 7856–36,156 lb. per sq. in. Transverse tests on bars 3 in. × 1½ in. × 6–12 in. were made in both directions of the bedding. The transverse strength is always very low when applied parallel to the bedding. The transverse strength (modulus of rupture) perpendicular to the bed was 900–4388 lb. per sq. in. Tensile tests showed the occurrence of definite lines of weakness not otherwise ascertainable, but harmful to the stone, as they allow more ready access of water to the interior of the marble. The tensile strength was 328–2254 lb. per sq. in. Repeated freezing and thawing of wet cubes resulted in a loss of weight and strength in most cases, though a few specimens gained slightly. In one case the loss in strength was over 28%. On repeatedly heating to 150° C. the specimens lost 1.9% by weight. The absorption (which is much less than the true porosity) should be expressed by volume; if expressed as a percentage of the weight of the specimen, a light marble might appear to be more absorptive than a heavier one, when actually the reverse is the case. In the specimens examined the absorption never exceeded 1.2%, the average being 0.2%. The apparent sp. gr. of calcite marbles is 2.70–2.73, and that of dolomitic marble 2.84–2.86. The porosity varied from 0.40 to 2.09, and the relation of absorption to total pore space is important in predicting the resistance of the marble to frost. The permeability of marble to air is much greater than to water; there is no relation between this permeability and the loss of strength on freezing. The

staining power was determined by drilling a $\frac{3}{8}$ in. hole to the centre of a 2 in. cube of the marble, filling the hole with eosin solution, and after six hours sawing the cube in half and noting the extent of the penetration. The results varied greatly, but could not be correlated with any other property. Volume-resistivity tests for showing the electrical insulating power indicated that the resistivity is greatly affected by moisture, but the values obtained with samples dried for several days in the laboratory air appear to be satisfactory. They lie between 1.0 and 1.2×10^6 . The effect of soaking test-pieces for three months in a solution of carbonic acid varied with different specimens, the dolomitic marbles being least affected. The permanent expansion between 0° and 100° C. was 0.2 – 0.3 mm. for each 3 ft. of length. On repeatedly heating to about 500° C. the permanent expansion, as well as the rate of expansion, was gradually reduced and became negligible after five or six heatings. Marble which has expanded on heating does not return to its original volume.—A. B. S.

Concrete; Manufacture of —. D. Dale, Newcastle-under-Lyme, Staffs. Eng. Pat. 136,075, 16.4.19. (Appl. 9678/19.)

THREE parts of sand and one of cement are mixed in a dry state, then moistened with water and feathers added and the whole thoroughly mixed. After being allowed to stand until partly set the mixture is beaten up so as not to allow it to set too firmly. The plastic concrete thus produced is frequently mixed whilst it is being used. The feathers are preferably added gradually during the mixing.—A. B. S.

Cement; Process of making —. H. D. Baylor, Sellersburg, Ind., Assignor to Louisville Cement Co., Louisville, Ky. U.S. Pats. (A) 1,323,952 and (B) 1,323,953, 2.12.19. Appl., 17.3.19.

CEMENT is rendered slower setting (A) by mixing the comminuted cement with quicklime in a proportion between 6 to 1 and 10 to 1 by weight, and stirring into the mixture the amount of water approximately necessary completely to hydrate all free calcium oxide, including that resulting from the break up of aluminates; or (B) by adding quicklime to the cement, comminuting the mass, adding oily or waxy material at the same time as the water necessary to hydrate all the calcium oxide, and grinding. In the case of (B) a plastic cement is obtained.—E. W. L.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron deposition; Electrolytic —. W. A. Macfadyen. Faraday Soc., Dec., 1919. [Advance proof.]

EXPERIMENTS were conducted in order to find the most favourable conditions for effecting a substantial electrolytic deposition of iron upon mild steel, using a solution of ferrous ammonium sulphate as electrolyte. Current was supplied from accumulators to ensure regularity, and the anodes consisted of plates of Swedish iron. The ratio of the active area of anode to cathode was always large. The mild steel cathodes were cleaned thoroughly, both chemically and by abrasion, and a film of copper was applied before the electrolytic deposition of iron. It was found later that it was possible to deposit iron directly upon steel

if the steel had been subjected previously to an acid electrolytic cleaning bath, making it the anode instead of the cathode, as is the usual practice. The effect of variation in concentration and acidity of the electrolyte at atmospheric temperature showed that solutions containing 315 grms. of ferrous ammonium sulphate per litre yielded deposits equally as good with current densities as high as 16 amp. per sq. ft. as those obtained from dilute solutions (50–100 grms. per litre). Some intermediate concentrations (100–300 grms. per litre) consistently gave pitted deposits. Trouble was experienced in neutral solutions from deposits, presumably some form of ferrous hydroxide, which was almost eliminated when the electrolyte was acidified. The cathode efficiency reached a maximum (98%) when the solution was of about 0.001 *N* acidity, and decreased progressively when the acidity was increased. After protracted use of the same solution the quality of the deposits deteriorated owing to the accumulation of organic impurities, but it was found possible to expel these by boiling the solution or to absorb them by means of wood charcoal. Experiments made at different temperatures showed that 65° C. was most satisfactory, as deposition could be effected from a concentrated solution at fifty times the rate possible in a cold dilute solution. If the current density exceeds 200 amps. per sq. ft. the deposit tends to have a specular appearance and the adhesion suffers. If the steel base with deposited iron be annealed above the A3 point for pure iron, the two become strongly welded together. Subsequent case-hardening is usually advisable to harden the electrolytic iron.

—C. A. K.

Ferromanganese; Saving of — by use of fluorspar in open-hearth furnace practice. E. Goldmann, Stahl u. Eisen, 1919, 39, 1385–1387.

INSTEAD of adding only a small quantity of fluorspar as in ordinary practice for fear of damaging the hearth, the author has added 1000 kilos. per charge without undue injury to the hearth. The greatest advantage of its use lies in the saving of ferromanganese. The author made cast steel shell with 0.6–0.9% Mn without the addition of ferromanganese or spiegeleisen. The phosphorus content was 0.1–0.15%, but other qualities were made with a maximum of 0.04% P. It was not possible to produce iron with carbon as low as 0.15% without the use of manganese. It is important to use a pig iron with the highest possible manganese content, this being attained if necessary by large additions of open-hearth furnace slag to the mixture. This keeps the sulphur low, and by the use of fluorspar a thick layer of thin fluid slag is formed, which protects the original manganese in the charge, and makes possible the removal of phosphorus and part of the sulphur.—T. H. Bu.

[Steel] process; Acid electric furnace —. L. B. Lindemuth. American Foundrymen's Assoc. Blast Furnace and Steel Plant, 1919, 7, 595–596.

THE acid process of steel making differs from the basic process in that it is a single slag process, and the slag varies considerably both in composition and quantity. The controlling factor of the acid process seems to be the quantity of iron oxide present at the time the charge is melted, irrespective of the method of its introduction. Before any additions are made to the charge the molten acid slag is principally a complex silicate of iron and manganese containing 50–60% SiO_2 . About 90% of the manganese in the charge passes into the slag as oxide, and the oxidation of the bath and of subsequent additions of manganese appears to be controlled by the FeO content of the slag. Iron oxide in the slag is not reduced satisfactorily by the addition of carbon, because an acid silicate dissociates less easily than a basic silicate, and also iron is more

stable in a silicate in which iron is the predominating base. Further, silica is reduced by carbon at the temperature attained near the arc, and the silicon in the metal may be increased by this reaction during a "blow." Iron oxide in the slag is reduced partially by additions of lime and manganese ore, thus enabling the necessary reducing conditions to be produced. A typical finishing slag contains SiO_2 58.70%, CaO 21.25%, MnO 12.01%, FeO 3.10%, MgO 1.15%, Al_2O_3 3.35%, P 0.003%, and S 0.005%. In order to overcome the variables introduced by rust or other oxidised products, the most satisfactory method would be to withdraw the slag immediately after the charge is melted. The view is expressed that the basic electric process gives conditions which tend to a fewer number of inclusions in the metal than the acid process.

—C. A. K.

Steel: Relationship between transverse rail fissures, flakes and defects in fusion welds in —.
S. W. Miller. Chem. and Met. Eng., 1919, 21, 729–733.

ALL the evidence indicates that transverse fissures, flakes and intergranular ruptures in welds are due to the same cause, *viz.*, films of oxide, which are possibly ultramicroscopic. These films are usually present in the ingot, and may be produced by overheating of the metal in the course of manufacture. When they are due to iron oxides in small quantity only they may be removed by heat treatment, as stated by Giolitti (this J., 1919, 289 A) and Humfrey (Carnegie Schol. Memoirs, Iron and Steel Inst., 1914, 4, 80), but this would probably not be possible when they are caused by larger amounts of iron oxide. Such defects in welds as are visible under the microscope may be eliminated by thorough fusion in the welding process, so as to bring all the oxide and dirt to the surface. This is more difficult in electric welding owing to oxidising conditions being more pronounced, and to the fact that the metal is being constantly added from the electrode. It is possible that ultramicroscopic films in welds may be eliminated by heating the weld in a reducing atmosphere. It is suggested that the examination of sound rails and of those known to contain fissures by polishing and etching small sections and bending them under the microscope would give further information, especially in the case of steel showing low elongation. Experiments indicated that welds made with good material will give from 22 to 30% elongation in the weld when tested in a piece $\frac{1}{2}$ in. thick, whereas welds containing films of oxide, even though invisible, will only show an elongation of 2 to 10%. The same low elongation is also to be observed in the case of flaky steel and defective rails.—C. A. M.

Steel; Solution theory of —, and the influence of changes in carbide concentration on the electrical resistivity. E. D. Campbell. Faraday Soc., Dec., 1919. [Advance proof.]

It is becoming recognised generally that the electrical resistivity of metallic solutions is dependent on the concentration and degree of dissociation of the solutes just as truly as is the conductivity of aqueous solutions, and it is only logical to express the concentrations in similar terms, *e.g.*, millatoms (mgrm.-atoms) per c.c. The influence of decarburisation of steel on the electrical resistivity has been examined. Similar bars cut from steels of different type were decarburised in an atmosphere of moist hydrogen, and quenched, and the resistivity of the bars before and after decarburisation was compared with that computed from Benedick's formula. Benedick's law assumes that equi-atomic concentrations in iron exert equal influence on the resistivity, and the specific resistance under consideration must be that of steel in the

hardened condition. The differences found between the measured and computed resistivities are so great that the formula cannot be considered as having any particular significance. The conclusions of Le Chatelier (this J., 1898, 669) concerning the influence of C, Si, Mn, and Ni, are confirmed, but his view that Cr, W, and Mo have but little influence on the resistivity of steel is not substantiated. If a steel, containing such elements, which possess a stronger affinity for carbon than has iron, is annealed, a large part of these elements will be found in the form of precipitated carbides when the metal is annealed, so that, not being in solution, these elements can have little effect. If the steel, however, is decarburised, a marked increase in resistivity is noted, due to the solution of the liberated element in the iron. Manganese and nickel show distinctly less influence on the resistivity than would be due to an equal atomic concentration of carbon. Figures obtained show that there must be some marked differences in the constitution of the carbides in various steels.

—C. A. K.

Chrome-nickel steels; Substitutes for —. E. Kothny. Stahl u Eisen, 1919, 39, 1341–1348.

WAR conditions in Germany necessitated economy in the use of nickel, and an investigation was carried out to find substitute alloy steels for nickel and chrome-nickel steels in highly stressed parts. The requisite properties after suitable heat treatment are high elastic limit, good elongation and reduction of area even with high tenacity, high resistance to impact, and fibrous fracture of longitudinal and transverse test pieces in combination with high tenacity. The alloying elements available were manganese and chromium, together with silicon. Tests were carried out on electric and Martin furnace heats first on small specimens and then in some cases on specimens of practical size. The results showed that only plain chromium or plain manganese steels will give the desired properties. The compositions recommended are C 0.20–0.45%, Mn 0.4–0.6%, Si 0.2–0.3%, Cr 1.0–1.3%, and C 0.2–0.4%, Si 0.2–0.3%, Mn 1.5–1.8% respectively. Silicon-steels, chromium-silicon steels, and manganese-silicon steels are not satisfactory for the purpose desired. As a case-hardening steel the following is recommended: C 0.1–0.2%, Mn 0.4–0.6%, Si 0.2–0.3%, Cr 0.8–1.1%.—T. H. Bu.

Self-hardening steels; Critical points of —. P. Dejean. Comptes rend., 1919, 169, 1043–1045.

A DISTINCT discontinuity between the formation of pearlite or troostite, and martensite has been previously noted (this J., 1917, 965). The critical point corresponding to the formation of the former has been denoted "A," and to the formation of the latter "B." From a study of the cooling curves of a nickel-chrome-copper steel, cooled from 700° to 100° C. in about 150 mins., but from different initial temperatures, the formation of martensite appears to occur in two stages, denoted by critical points B₁ and B₂. The point "A" is indicated only when the initial temperature of cooling is 790° C. When cooled from 800° C., "A" is considerably suppressed and a second critical point (B₁) is observed about 420° C. A further point (B₂) occurs at about 230° C. if the steel is cooled from 850° C., and when cooled from still higher temperatures B₁ disappears and the point B₂ exists alone. The steel is relatively soft if only the critical point "A" is in evidence during cooling, but becomes harder when B₁ predominates, with still greater hardening when point B₂ is evident. It is concluded that the maximum hardness is attained in at least two stages and that for the same steel there are several marsensitic forms.

—C. A. K.

[Steel] hydrogen cylinders; Results of cold working of —. E. Bock. *Stahl u. Eisen*, 1919, 39, 1467—1470.

MECHANICAL tests were made on pieces of a hydrogen cylinder which exploded disastrously in use although it had successfully withstood the acceptance test under a pressure of 225 kilos. per sq. cm. The fragments showed generally longitudinal fracture, i.e., in the direction of drawing. The mechanical tests showed high elastic limit and small elongation and reduction of area, and the effects of cold working were traceable throughout the cross-section of the pieces. The tenacity was satisfactory, but brittleness was shown in bending and impact tests, especially on transverse specimens. The brittleness could be removed by annealing for 10 mins. at 600° C. Microscopical examination showed non-metallic inclusions elongated in the direction of drawing, also that the material had been drawn into layers.—T. H. Bu.

Sulphur and chromium in steel; Determination of —. L. A. Goldenberg. *Chem. and Met. Eng.*, 1919, 21, 628.

SULPHUR is determined by the evolution method and chromium by a slight modification of the silver nitrate-ammonium persulphate method. The sample is placed in an Erlenmeyer flask which is closed by a two-holed rubber stopper carrying a thistle funnel through which sulphuric acid is added, and a tube leading into a vessel containing ammoniacal cadmium chloride solution. The sample is heated with the sulphuric acid, and when evolution is complete the cadmium chloride is titrated, with the addition of starch solution and hydrochloric acid, to a deep blue end point with standard potassium iodide-potassium iodate solution. For the determination of chromium, nitric acid-silver nitrate solution is added to the contents of the Erlenmeyer flask, which are boiled gently until nitrous fumes are expelled, the mixture is diluted, heated to boiling, ammonium persulphate solution is added, and the boiling is continued until manganese dioxide is completely precipitated. Hydrochloric acid is then added to prevent sudden boiling over and to destroy the manganese dioxide, and the contents of the flask are boiled for about 15 mins. until the silver chloride is coagulated. After cooling, potassium ferriocyanide is added, and the mixture is titrated with standard ferrous ammonium sulphate solution which has been standardised against a standard steel. The method presents considerable advantage in point of time over the older permanganate process, there is less risk of inaccuracy through splashing, and the end point of the titration is more definite. Moreover, by using sulphuric acid as the solvent in the sulphur determination the difficulty experienced when using hydrochloric acid of acid fumes passing into the cadmium solution and causing loss of ammonia by volatilisation as ammonium chloride is obviated.—S. S. A.

Steel; Determination of gas in —. P. Oberhoffer and A. Beutell. *Stahl u. Eisen*, 1919, 39, 1584—1590.

THE gases dissolved in iron and steel are determined by means of a new apparatus consisting of a quartz tube in a magnesia crucible heated externally by an electric furnace and exhausted to a vacuum by means of a mercury pump. Steel together with twice its weight of a 50/50 tin-antimony alloy is placed in the tube, which is then exhausted and heated to a temperature of 1100° C. In 30—40 mins. the whole of the dissolved gas is evolved. This is then collected and analysed. A number of samples of acid and basic steels both before and after deoxidation and at various intervals of casting were examined. The composition

of the evolved gases varied within the following limits: CO, 0—15.4, CO₂ 43.7—88.7%, H₂, 3.8—41.0, N₂, 1.8—27.9. The volume of gas evolved ranged from 38.7 c.c. per 100 grms. of steel in the case of a basic steel to 195 c.c. per 100 grms. in the case of an acid steel. Deoxidising reduced the volume of gas in acid steel and increased it in basic steel. Rolling an acid steel diminished the amount of gas evolved from 118 c.c. to 63 c.c. per 100 grms.

—J. W. D.

Soaking pits; Electrically heated — in the steel industry. T. F. Baily. *Amer. Iron and Steel Inst.*, May, 1919. *Chem. and Met. Eng.*, 1919, 21, 624—627.

FOR heating operations subsequent to melting and refining, electrically heated furnaces effect considerable saving of labour as compared with fuel-fired furnaces, and on account of the greater precision of the treatment the percentage of material rejected through defective heat treatment is much lower. Thus, in electrically heated soaking pits, although the fuel cost is higher than in fuel-fired pits, the material produced is not so liable to defects caused by lack of uniformity in the temperature of the heated ingot, excessive oxidation of the ingot, and the like. The author describes a continuous type of electric reheating furnace adapted for rolling mills of relatively small capacities or for reheating steel of high quality, and a combined fuel and electric furnace suitable for dealing with a large tonnage. For exact work in annealing, hardening, and other heat treatment the higher fuel cost of electric heating plant is more than compensated by the superiority of the material produced.—S. S. A.

Electric rotating furnace; The Booth — [for melting metals]. C. H. Booth. *Amer. Inst. Chem. Eng.*, June, 1919. *Chem. and Met. Eng.*, 1919, 21, 636—638.

THE furnace, which is built in several sizes, comprises a shell carried on motor-driven rollers working without gearing in tracks on the shell, and is arranged to revolve at the rate of two revolutions per minute. The current is carried to the electrodes by short pieces of flexible cable which connect to the track and the current is supplied to the tracks by shoes which press against them and form a sliding contact. The electrodes are regulated in the smaller furnaces by hand screws and in larger plant automatically. The lining is made with as few joints as possible and the door is in one piece with a hole in the centre to admit the electrode. In this type of furnace graphite electrodes are used on account of their greater conductivity. The furnace and electrical connections are simple in design, the charge is uniformly mixed, and the cost of operation and upkeep charges are low.—S. S. A.

Melting non-ferrous metals and their alloys in the electric furnace. E. F. Collins. *Chem. and Met. Eng.*, 1919, 21, 673—679.

THE requirements for melting non-ferrous metals and their alloys are continuity of operation, freedom from oxidation and volatilisation, that the slags should not mix but be easily removable, and that the furnace and its atmosphere should be entirely free from sulphur. The transfer of heat is best accomplished by radiation to the top of the bath and conduction to the bottom. The best type of furnace is one in which a readily controllable amount of heat is generated between a fixed and a movable electrode, the distance between them being maintained so that they give rise to many chains of series and multiple contact or resistance areas, enveloping adjacent electrode faces. This type is described in detail. Comparative costs of melting

in electric and fuel-fired furnaces are tabulated and sources of loss in each type are outlined. From a summary of the results obtained the author concludes that for brass melting the electric furnace is superior.—W. J. W.

Aluminium corrosion as affected by basic pigments.
H. A. Gardner. Paint Manufacturers' Assoc., U.S.A., Circ. No. 79. Dec., 1919. 2 pp.

UNDER severe conditions of exposure, aluminium shows very rapid corrosion, resulting in a rough surface to which soot will adhere tenaciously. Pigments of a basic nature, i.e., red lead, white lead, zinc oxide, etc., when ground in water etch aluminium rapidly, whilst silicious earth and other neutral crystalline pigments have no such action. Thus, if aluminium surfaces for such purposes as automobile bodies, etc., be primed with a paint composed of a mixture of basic pigments and silicious earth pigments, under favourable conditions, etching of the surface with production of a firm foundation for succeeding coats will take place. Progressive corrosion could be inhibited by application of many outer coats. For other forms of aluminium which may be exposed to the weather, the use of a high-grade spar varnish is recommended to obviate obscuration of the bright colour of the metal.—A. de W.

Metal deposits: Measurement of the minimum thickness of — by their electromotive force. S. Procopiu. Comptes rend., 1919, 169, 1030—1031.

WHEN zinc is deposited upon an electropositive metal the E.M.F. diminishes rapidly at first and more slowly later. If the current is stopped, the deposited layer dissolves and gives rise to a counter E.M.F. which gradually increases to a point at which a sharp increase takes place. Thus, with a deposit of zinc 3.5μ in thickness, on platinum, the E.M.F. after stopping the current increases from 0.011 to 0.14 volt in 7 mins., to 0.85 in 8 mins., and to 1.02 volts in 9 mins. If deposits of more than minimum thickness are allowed to dissolve and a curve is drawn with the thickness of the metal as abscissa and the time taken to reach the break in the E.M.F. as ordinates, a point is obtained which represents the minimum thickness deposited electrolytically, assuming the E.M.F. to be set up as soon as the metal is deposited. If solution only of the metal occurred the curves representing the thickness of the deposit : time, would be of equal inclination to the abscissa, but this is not the case :—

	Metal on which zinc is deposited.					
	Al.	Pt.	Fe.	Ag.	Cu.	Ni.
Tangent of angle ..	0.13	0.24	0.3	0.4	0.7	1.1
Minimum thickness of zinc deposit (μ) ..	0.3	0.8	1.6	2.8	4.2	4.8

The varying values for the minimum thickness of a zinc deposit on different metals are explained by the extent of diffusion of the zinc layer into the underlying metal, or by an alloying action between the two metals.—C. A. K.

Antimony ores; Treating —. G. P. Hulst. Amer. Inst. Min. and Met. Eng., Sept., 1919. Chem. and Met. Eng., 1919, 21, 727.

THE demand for antimony for shrapnel during the war made it profitable to work ores containing as little as 20% Sb, and many small mines were opened. Low-grade sulphide ores (20—45% Sb) were produced in Nevada, California, Idaho, Utah, and Mexico, whilst the principal oxide ores came from Mexico and Oregon. High-grade sulphide ores (stibnite) with 55—60% Sb were imported into the United States from Bolivia, China, and

Alaska. The ores were mixed with waste material such as battery plates, lead oxide, paint, etc., to furnish the necessary lead, and were treated in residue and blast furnaces. The charges consisted of various sulphide ores, containing 20—60% Sb and 6—45% SiO_2 , or of oxide ores with 20—40% Sb and 10—45% SiO_2 . All ores containing silver (e.g., 3.40%) were treated in the residue furnace, the sulphur, iron, and copper-forming matte containing part of the silver, whilst the bulk of the latter was found in the lead bullion. The antimony slag was sufficiently low in silver to justify its being smelted in the blast furnace to antimonial lead. Owing to the high proportion of zinc and arsenic in lead refinery by-products a slag was used containing:— SiO_2 , 26%; FeO , 40%; and CaO and ZnO , 20—24%. The average amounts of antimony and lead in the slag were 0.66 and 2.36% respectively. The blast furnace loss was 2.4% Sb and 1.5% Pb. The furnace charge varied from 2500 to 3000 lb., and the coke ratio was 13%. Blast pressure was maintained at 10—12 oz. The two furnaces smelted 60—90 tons of material per day, and produced 30—35 tons of antimonial lead of the following average composition:—Sb, 13.00; Cu, 0.15; As, 0.75; and Pb 86.1%.—C. A. M.

Lead-sodium-mercury and lead-sodium-tin alloys.
T. Goebel. Z. Ver. deuts. Ing., 1919, 424—430. Chem.-Zeit., 1919, 43, Rep., 312.

WHEN an alloy of lead, sodium, and mercury is cast in a cold mould, "pipes" are formed in the casting. These "pipes" are more pronounced the greater the mercury content of the alloy, and the more nearly the percentage of sodium present approximates to an average value of 2—3%. There is very little pipe formation if the alloy is poured into a warm mould. The maximum value of the hardness of a lead-sodium-mercury alloy containing 1.8% Na is the same as the maximum hardness of a lead-sodium or a lead-sodium-tin alloy containing 0.8% Na. In the case of lead-sodium-mercury and lead-sodium-tin alloys, the same hardness is obtained with a larger percentage of sodium present than in the case of the binary lead-sodium alloys. The tenacity of these latter alloys is considerably increased by addition of tin. The tenacity of the lead-sodium-mercury and lead-sodium-tin alloys diminishes with increase in the percentage of sodium present. Lead-sodium-mercury alloys containing 1%—2% Na, on account of their hardness and the small tendency to crack which they exhibit, are specially suitable for use as bearing metals.—J. S. G. T.

Cobalt; Passivity of —. H. G. Byers and C. W. Thing. J. Amer. Chem. Soc., 1919, 41, 1902—1908.

WHEN cobalt is used as anode in the electrolysis of 0.02N sulphuric acid or sodium sulphate at 0° C. it becomes passive if a high current density is employed, but if a low current density is used it remains active and passes into solution. When potassium bichromate is present cobalt readily assumes the passive condition under all circumstances. It differs from iron and nickel mainly in the fact that it will not become passive when used as anode with low current density, but if it has once assumed the passive condition it will remain so even though the current density is reduced. (See also J. Chem. Soc., Feb., 1920.)—J. F. S.

Metals; Atomic structure of — in solid solution.
A. L. Feild. Chem. and Met. Eng., 1919, 21, 566—570.

SOLID solution alloys, comprising hardened steels and electrical resistance alloys, differ in physical properties from their components. They probably are analogous to supercooled liquids with the same

atomic structure as the molten metals, and they do, in fact, approach the latter in similarity of properties such as electrical resistance and temperature coefficient of resistance. The formation of an amorphous phase is assumed and is confirmed by experiments on the specific resistance of nickel-chromium and gold-silver alloys. The hardness of alloys is also due to the presence of amorphous metal. Electrical methods of examination of metals are recommended.—W. J. W.

Coagulation [of gold sols]. A. Westgren. *Arkiv Chem. Min. Geo.*, 1917-18, 7, No. 6, 1-30.

The velocity of coagulation by means of electrolytes is independent of the size of the colloidal particles. The velocity of coagulation by means of electrolytes is greater the larger the migration velocity of the anion. The dependence of the velocity of coagulation on the temperature is due both to the change in the velocity of the Brownian movement and to the change in the specific coagulation power of the electrolyte with temperature. (See also J. Chem. Soc., Feb., 1920.)—J. F. S.

PATENTS.

Cast-iron; Refining —. H. Barnes, Assignor to R. H. Genter, Chattanooga, Tenn. U.S. Pat. 1,322,516, 25.11.19. (Appl. 6.2.19.)

Pig-iron is melted in a chamber having a curved and tapering bottom portion and run direct into the rear end of a refining chamber, at the front end of which is a gas producer. Rear blast pipes, with internal fuel jet pipes, project downwards and rearwards into the bottom of the melting chamber, and front blast pipes project in a similar manner into the front end portion of the refining chamber above the hearth.—E. W. L.

Alloy steel; Surface-stable —. P. A. E. Armstrong, Londonville, N.Y. U.S. Pat. 1,322,511, 25.11.19. (Appl. 24.5.19.)

An alloy steel of high surface stability contains 3-50% Cr and 0.5-3.5% C. The carbon content must not be more than 10% of the chromium and silicon together if the latter be less than 13%, or more than 16.6% if the chromium plus silicon be more than 13%. Silicon (5-8%) should be present to the extent of over twice the carbon content, and silicon and chromium together between 5 and 58%. —C. A. K.

Magnesium; Process of electrodepositing —. G. O. Seward, New York. Eng. Pat. 120,908, 11.11.18. (Appl. 18,467/18.) Int. Conv., 19.11.17.

See U.S. Pats. 1,310,119-50 of 1919; this J., 1919, 643 A. The molten electrolytic bath contains magnesium, sodium, and barium fluorides, and has sp. gr. above 3 and preferably approximating 4.

Crucible furnaces. W. A. Shilton and R. A. Munden, Coventry. Eng. Pat. 135,620, 17.10.18. (Appl. 19,810/18.)

A CRUCIBLE furnace, heated by gas or hydrocarbons, is fitted with a cover having a central opening for the escape of the hot gases from the furnace. The

cover contains an annular air chamber through which air for combustion at the burner is circulated and preheated, and the refractory slab forming the bottom of the cover may be shaped so as to direct the hot gases into the crucible.—C. A. K.

Electric arc shaft furnaces. J. Bibby, London. Eng. Pat. 135,905, 28.11.18. (Appl. 19,671/18.)

IS furnaces of the type having a crucible surmounted by a shaft, from which gases are withdrawn and re-introduced into the crucible portion for cooling purposes, coal dust or other finely-divided carbonaceous material is caused to enter with the gases in order to reduce the oxidation of the electrodes. The endothermic reaction between the carbon and the carbon dioxide in the gases also increases the cooling effect.—C. A. K.

Furnace; Metal-melting —. L. C. Harvey, Malden. Eng. Pat. 136,213, 12.11.18. (Appl. 18,529/18.)

A FURNACE, capable of being rocked, is fitted with a charging tube through the arch, which allows the charge to be fed underneath the slag covering molten metal on the furnace bottom. The central portion of the bed of the furnace is level, and one end inclines gradually to a pouring spout for the complete removal of metal and slag. The opposite end of the bed has a sharp inclination adapted for the agitation of the metal during rocking, and a tubular spout, dipping below the surface of the metal, allows the withdrawal of small quantities of molten metal free from slag.—C. A. K.

Furnaces [for heat treatment]. H. Fuller, Manchester, and R. A. Bedford, Sheffield. Eng. Pat. 136,270, 12.12.18. (Appl. 20,739/18.)

For the tempering of steels by the salt bath process, two crucibles mounted in a single furnace casing are employed. One of the crucibles is heated in the usual manner by one or more gas burners, and the second is heated wholly, or partly, by the hot products of combustion passing from the first crucible chamber.—C. A. K.

Alloys of copper, zinc, and lead; Manufacture of —. J. P. Arend, Dommeldange, Luxembourg. Eng. Pat. 135,702, 31.1.19. (Appl. 2195/19.)

THE alloys contain copper and zinc in about the same proportion as for brass (15-45 Zn, 85-55 Cu) together with a quantity of lead (e.g., 10-60%) in excess of that necessary for the formation of a saturated solution of lead in the other metals. The excess of lead renders the alloys plastic and suitable for the construction of bearings. The alloys possess the physical qualities of phosphor bronze.—C. A. K.

Cast metal objects; Process of producing —. E. C. R. Marks, London. From Kohler Co., Kohler, Wis., U.S.A. Eng. Pat. 135,893, 1.12.19. (Appl. 17,731/18.)

METAL moulds are coated with a material consisting of 88% of quartz, 10% of white clay, and 2% of borax, which is applied by means of a spray and acts as a heat insulator, thereby protecting the casting from chilling.—J. W. D.

Copper-aluminium alloy. W. J. Haywood, London. Eng. Pat. 135,963, 10.12.18. (Appl. 20,550/18.)

A COPPER aluminium bronze containing 6.2-11.0% Al, 0.5-5.0% Fe, 0.1-6.0% Ni, 0.06-1.0% Ti, and 0.03-3.0% Mn.—J. W. D.

Lead and silver from sulphide ores and metallurgical products; Recovery of —. Amalgamated Zinc (De Bavay's), Ltd., Melbourne, Australia, and S. Gancelin, Brooklyn, N.Y., U.S.A. Eng. Pat. 135,968, 12.12.18. (Appl. 20,761/18.)

THE ore is heated in a closed furnace with zinc

chloride, and the lead and silver chlorides in the product are either extracted together with a cold concentrated brine solution or a brine solution containing cupric or ferric chloride, or extracted separately by leaching out the lead chloride with hot concentrated brine containing 3—4% of zinc chloride and removing the silver chloride with a cyanide solution or a brine solution containing 2—4% of ferric chloride. Zinc-free lead is recovered by crystallisation of the chloride and remelting of the crystals in a bath of zinc chloride in the presence of molten lead and zinc, when zinc chloride is formed and pure lead tapped off.

—J. W. D.

Sintering concentrates, distilling shale, and the like; Apparatus for —. J. M. Berglund, Ludvika, Sweden. Eng. Pat. 136,076, 17.4.19. (Appl. 9903/19.)

A hollow cylinder divided into compartments by radial partitions, is mounted on a horizontal hollow shaft. Shallow trays with perforated bottoms are fitted in the separate compartments at the periphery of the drum, and are adapted to receive material to be heated as the drum rotates. Suction is applied to the central shaft and slots on the upper portion allow air to be drawn through each compartment in turn as it passes over the opening. An ignition appliance, e.g., a fire-grate, in contact with the drum, is fixed near to the feed hopper. Guide-plates allow of the convenient feeding into the sintering trays, and of the discharge of the material after heating.—C. A. K.

Ores; Concentration of —. S. Tucker, E. Edser, and Minerals Separation, Ltd., London. Eng. Pat. 136,255, 10.12.18. (Appl. 20,541/18.)

Is a froth-flotation process the mineral separating agent consists of a mixture of a soap solution with an alkali sulphide or a mixture of the ingredients necessary to produce soluble soaps and alkali sulphides. Such a mixture may be formed, for example, by treating an alkali hydroxide or carbonate with sulphur and adding a fatty acid.

—C. A. K.

Flotation apparatus and process. W. L. Ziegler, Sunset, Idaho. U.S. Pat. 1,324,139, 9.12.19. Appl., 4.4.17.

A FLOTATION process for the treatment of ore pulp composed of a mixture of ore in fine division, water, and a frothing agent, consists in injecting air into an upwardly moving column of the pulp to produce a body of froth at the top, and beating the froth in a confined space at the top of the column as it leaves the column so as to break up the larger air bubbles and produce a creamy froth whilst permitting the excess of air to escape. The froth and the gangue are then separated.—G. F. M.

Heat-treating and quenching device. T. F. Baily and F. T. Cope, Assignors to The Electric Furnace Co., Alliance, Ohio. U.S. Pat. 1,322,750, 25.11.19. Appl., 12.8.18.

A QUENCHING tank is located beneath, and extends beyond one side of, a vertical furnace. Articles to be treated are carried on a track above the tank, and raised into the furnace, afterwards being discharged into the tank, in which they may be held suspended from the track.—C. A. K.

Gold; Method of recovering —. R. Thayer, Philadelphia, Pa. U.S. Pat. 1,323,124, 25.11.19. Appl., 9.7.18.

COLLOIDAL gold-bearing sands or ground rock ores containing colloidal gold are roasted in presence of an alkali, to render the gold more readily recoverable.—C. A. K.

Cyaniding process; Electrolytic —. W. A. Hussey, Oakland, Cal., Assignor to J. H. Alling and F. M. Wright, San Francisco, Cal. U.S. Pat. 1,324,352, 9.12.19. Appl., 15.4.13. Renewed 17.4.19.

METAL-BEARING material is mixed with a solution of sodium cyanide together with a halogen sodium compound, and the solution is electrolysed, using a mercury cathode. A current of sufficient intensity to form a halogen-cyanogen compound and sodium is employed, and the metallic sodium is removed from the action of the current.—C. A. K.

Solder; Aluminium —. C. L. Bonsteel, Moose Jaw, Sask., Canada. U.S. Pat. 1,323,520, 2.12.19. Appl., 11.1.19.

An aluminium solder comprising a mixture of 29 lb. of tin, 11 lb. of zinc., 2 lb. of phosphor-tin, 2 lb. of aluminium, and 2 grains of bismuth.—C. A. K.

Metals; Precipitation of — from solutions. A. Gordon, Johannesburg, Transvaal. U.S. Pat. 1,323,588, 2.12.19. Appl., 18.2.18.

METALS are precipitated from solutions by means of amalgamated aluminium.—E. W. L.

Alloy. A. Cohn, New York. U.S. Pats. (A) 1,323,833 and (B) 1,323,834, 2.12.19. Appl., (A) 2.5.19 and (B) 6.6.19.

(A) THE alloy contains platinum together with from 1—15% of gold. (B) The alloy contains an excess of refined platinum, together with iridium and gold.
—A. E. D.

Oxidation of molten metal; Method of preventing —. F. F. McIntosh, Glen Osborn, Pa. U.S. Pat. 1,324,458, 9.12.19. Appl., 29.5.19.

WHEN the metal is being poured a protecting blanket of non-oxidising vapour heavier than air is generated by the heat of the metal from a substance which is liquid at atmospheric temperatures and pressures.—J. W. D.

Coating metals with mercury; Method of —. J. P. A. McCoy, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,324,835, 16.12.19. Appl., 12.4.15.

THE surface of a piece of tin is coated with mercury and the mercury transferred from the tin to the surface to be coated by placing the coated surface of the tin, wet with hydrochloric acid, upon the surface to be coated, rubbing the two surfaces together, and removing the tin and acid.—J. W. D.

Hardness of metals on the Brinell system; Portable spring-actuated devices for testing the —. F. C. Fairholme, W. H. Hatfield, and G. Stanfield, Sheffield. Eng. Pat. 136,129, 22.8.19. (Appl. 20,617/19.)

Steel; Apparatus for the production of — directly from pig iron. A. Nielsen, Copenhagen. U.S. Pat. 1,318,906, 14.10.19. Appl., 6.8.10.

XI.—ELECTRO-CHEMISTRY.

Temperature regulator; [Electric] furnace —. W. P. White and L. H. Adams. *Phys. Rev.*, 1919, 14, 44—48.

By making the heating coil of an electric furnace one arm of a Wheatstone bridge and combining this with a galvanometer regulator, thus keeping the resistance of the coil constant, the temperature of electric furnaces may be kept constant. The device is effective regardless of variations in the current supply and requires no attention, particularly in the case of furnaces which are not directly influenced by the temperature of the room or where the surrounding air is kept constant. The arrangement operates as follows: Changes in the temperature of the furnace and consequently in the resistance of the heating coil operate a beam which either hits or misses a contact maker which controls a suitable relay. This relay operates a larger magnet which controls the main current. The power available in this regulator is very large, nothing has to be inserted in the furnace cavity, and there is practically no lag. By means of this regulator furnaces at temperatures between 500° C. and 1400° C. may be kept constant to 0.1° for hours.—J. F. S.

Electrode; The Söderberg self-baking continuous —. J. W. Richards. *Trans. Amer. Electrochem. Soc.*, 1920, 1—15. [Advance copy.]

AN unbaked electrode mixture of coke, anthracite, pitch, and tar is fed continuously to the furnace, and the mass is baked by heat conducted from the lower end of the electrode, or by the heat contributed by hot gases or by radiation, or by heat derived from the passage of current through the baked portion. The electrode mixture is stamped into an iron casing, and new sections of the casing are bolted, riveted, or welded to the upper part of the casing as required. The thin casing may be provided with internal perforated projecting ribs, the casing thus serving to support the unbaked mixture, to reinforce mechanically the unbaked portion, and to facilitate the passage of current from the electrode holder to the electrode. The holder encircles the iron casing near the roof of the furnace, and the baking usually begins a short distance above the electrode holder. The baked carbon is hard, dense, and of the quality of previously-baked carbon; the use of the electrodes improves the regularity of running of electric furnaces, and they are cheaper than ordinary carbon electrodes in furnaces in which they can be used.—B. N.

Electrochemical production of organic compounds; Commercial possibilities in —. C. J. Thatcher. *Amer. Electrochem. Soc.*, Sept., 1919. *Chem. and Met. Eng.*, 1919, 12, 663—666.

THE advantages of and objections to the adoption of electro-chemical methods of producing organic compounds are enumerated, and the catalytic processes involved and the use and nature of the diaphragms used are briefly discussed. Suggestions for processes of commercial practicability include manufacture of alcohol, aldehydes, azo and hydrazo compounds, dyestuffs of the triphenylmethane type, sulpho acids, etc. The industry has reached its greatest development in Germany.—W. J. W.

Hydrogen overvoltage. II. Applications of its variation with pressure to reduction, metal solution and deposition. D. A. MacInnes and A. W. Contieri. *J. Amer. Chem. Soc.*, 1919, 41, 2013—2019.

A CHANGE in pressure on chemical reactions involv-

ing the evolution of hydrogen brings about changes in the rate of reaction and in the reaction efficiency which are in the direction expected from the change of hydrogen overvoltage with pressure. These include a decrease in the rate of solution of metals in electrolytes, an increase in the efficiency of reduction by metals, and an increased efficiency of metal deposition.—J. F. S.

Colloids; New method of electric synthesis of —. T. Svedberg. *Med. K. Vetensk. Nobelinst.*, 1919, 5, No. 10, 1—18.

HIGHLY disperse gold and silver sols may be obtained by the following method: A quartz tube, 1 mm. diam., in which a small hole is bored carries two electrodes which enter at the top and bottom and are arranged so that the arc will be formed opposite the hole. A current of nitrogen enters the quartz tube both at the top and at the bottom. This tube is placed in a glass jacket, which contains about 30 c.c. of the dispersion medium (alcohol), and which in its turn is surrounded by a cooling jacket containing ice and salt or solid carbon dioxide and alcohol. An electromagnet is placed with its poles on either side of the small hole in the quartz tube. The current (1 amp., 220 volts) is switched on and an arc of the usual type appears for about a second, then, owing to the melting of the lower electrode (anode), the quartz tube becomes somewhat stopped and the electrode is protected from the dispersion medium; the arc becomes a pointed flame, and this is drawn through the hole in the tube by the action of the magnet. Metallic clouds appear and are absorbed by the dispersion medium.—J. F. S.

PATENTS.

Electric furnaces. E. and W. Waring, Sheffield. *Eng. Pat.* 135,674, 31.12.18. (*Appl.* 21,863/18.)

THE furnace is provided with a circular undulating hearth sloping downwards from the walls into a recess, and rising again to a projection extending upwards in the centre of the hearth. The electrodes are arranged in three sets of groups, one set of groups in the outermost higher part of the hearth, an intermediate set of groups in the lower part of an undulation nearer the centre, and a central set of groups radiating from the centre and extending between groups of the intermediate set. The electrodes are grouped in such a manner that the largest number and smallest size are in the outermost groups, with a smaller number of larger electrodes in the groups nearest the centre, and in the

radiating groups the largest electrodes are also nearest the centre of the hearth. A number of electrodes may be interconnected upon a water-cooled box or frame to form a group, and any number of the boxes or frames may be interconnected by water pipes to form a single water-cooled system. A three-phase supply system is connected in delta, in such a manner that each outer main is connected to a series of groups of electrodes consisting of intermediate groups alternating with outermost groups, each series being closed upon itself to form a single electrode. The inner main is directly connected to one of the central set of groups, which are interconnected amongst themselves to form the third electrode, the sides of the delta being formed through the molten material.

—B. N.

Electric furnace. F. Jacoviello, Milan, Italy. U.S. Pat. 1,324,156, 9.12.19. Appl., 3.1.19.

THE material to be heated is contained in a number of cup-shaped vessels arranged in line, and separated by and embedded in powdered material of low electrical conductivity. The vessels themselves have a relatively high electrical conductivity. The conducting electrodes are embedded in the powdered material at the two ends of the series of vessels, so that the current traverses the material of low conductivity alternately with the vessels of high conductivity. The material surrounding the vessels is thus highly heated by the current, but the vessels themselves are not directly heated by the current owing to their low resistance.—W. F. F.

Electro-osmotic apparatus for removing liquids from substances; Method and apparatus for charging material to —. Apparatus for electro-osmotically removing liquids from materials. Elektro-Osmose A.-G. (Graf. Schwerin Ges.), Berlin. Eng. Pats. (A) 135,815 and (B) 135,819, 25.6.18. (Appls. 10,453 and 10,458/18.) Int. Conv., 20.10.17.

(A) THE material is charged into an electro-osmotic apparatus of the filter-press type by feeding it along the electrode at which the liquid is separated. The charging openings are arranged next the electrodes at which the liquid is separated, and the charging ducts may extend through the electrodes and terminate in nozzles directed radially. (B) The anodes, in apparatus of the chamber filter-press type, consist of solid plates hollowed out on each side to form double chambers, and are arranged alternately with two perforated plates as cathodes held by intermediate and outer frames to form permeable chambers.—B. N.

Resistance material; Electrical — and process of making. O. Hutchins and A. W. Olver, Assignors to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,322,573, 25.11.19. Appl., 25.3.19.

A SHAPED body of clay, containing iron oxide and silicon carbide substantially free from carbon, is heated to a temperature sufficient to fuse the clay and reduce at least a portion of the iron oxide.

—B. N.

Compounds; Method of decomposing — [by electrolysis]. V. M. Weaver, Harrisburg, Pa., Assignor to Weaver Co., Milwaukee, Wis. U.S. Pat. 1,323,936, 2.12.19. Appl., 24.1.16.

THE compound is decomposed by electrolysis, one of the products liberated being trapped at one portion of the top of the mass, whilst a second liberated product is made to pass off at another portion, by directing all the electrolytic action transversely from the vertical zone of one of the products to the vertical zone of the second portion.—B. N.

Electrolytic apparatus. A. J. MacDougall, Assignor to National Electro Products, Ltd., Toronto, Canada. U.S. Pat. 1,324,511, 9.12.19. Appl., 16.4.19.

A BI-POLAR electrode is provided with a separate chamber behind each face, and a series of transverse ribs are formed on each face, with a series of gas openings immediately below the ribs, and communicating with the respective chambers. A series of electrolyte openings are arranged in each face, immediately above each rib, communicating with the respective chambers, and a sheath of porous non-conducting material is fitted over the electrode so as to embrace the opposite faces.—B. N.

Electrolytic apparatus. L. W. Chubb, Edgewood Park, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,324,797, 16.12.19. Appl., 27.4.17.

IN electrolytic apparatus comprising a number of cells adapted to give off combustible gas during their operation, a manifold conduit communicates with the interior of each of the cells, and means are provided for burning the gases which collect in the conduit by means of air supplied thereto.—B. XII.—FATS; OILS; WAXES.

Olive oils; Refining of —. P. Artmann. Oel- u. Fettind, 1919, 1, 196—199. Chem. Zentr., 1919, 90, IV., 627.

DALMATIAN olive oils with a greenish tint require special treatment in refining. Decolorising is accompanied by small physical and chemical changes. Three kinds of colouring matters are present in olive oil: yellow, green (chlorophyll), and brown. The yellow and brown matters tend to be more completely adsorbed by certain agents than the green, so that by prolonged treatment or by the use of excess of decolorising agent, the oil may have a more pronounced greenish shade than before. This was particularly the case when "oleicrystal," fuller's earth, or kieselguhr was used. In the case of "eponite" the selective adsorption was less pronounced for the yellow colouring matter, so that the yellowish tint tended to persist. Quite apart from the influence of mere filtration, "eponite" had a distinct effect in removing acidity. Together with the oxidation, there is a partial loss of saturated glycerides in consequence of the lower adsorption of the unsaturated glycerides, which loss compensates or even exceeds the influence of the oxidation if the time of the refining process be prolonged or the quantity of decolorising agent or the temperature be increased. "Eponite" did not unfavourably affect the flavour, it improved the tint

of the oil, and appears preferable to other decolorising agents for the treatment of olive oil.—J. F. B.

Whale oil; Hydrogenated — P. Battenberg and J. Angerhausen. Z. Unters. Nahr. Genussm., 1919, 38, 199–206.

WHILST the usual analytical values of hydrogenated whale oils do not differ greatly from those of solid animal edible fats, the quantity of cholesterol and of unsaponifiable matters present affords means, to a certain extent, of differentiating the fats. Hydrogenated whale oil yields about 0.9% of unsaponifiable matter and 0.01% of cholesterol, the quantities for animal fats being 0.25% and 0.1% respectively. The unsaponifiable matter of whale oil, after removal of the cholesterol, is distinctly optically active ($[\alpha]_D^{20} = +2^\circ$), whilst that of animal fats is optically inactive. When crystallised from acetone, whale oils yield a larger quantity of insoluble glycerides than do animal fats, and the glycerides remaining soluble in this solvent have a high iodine value. Hydrogenated whale oils give a positive reaction with the test described by Tortelli and Jaffe (this J., 1915, 1102).—W. P. S.

Soaps; Process for the manufacture of economical — R. Gans, Berlin, Grünwald. Ger. Pat. 313,526, 25.6.18.

SOAP is mixed with hydrated silicates capable of exchanging their bases, which comprise iron oxides or other bases in addition to aluminium oxide. The silicates are added to the soap in the form of an extremely fine powder or as gels or sols or are produced in such forms in the soap solution or during the saponification of the fat in a state of intimate mixture. These hydrated silicates liberate a portion of their alkali on wetting with water in the same manner as soaps and have a detergent action. The proportion of such silicates may be varied within wide limits and may amount to 82% or more. The economy in the consumption of soap thus effected is estimated at 30–60%, according to the hardness of the water and the quantity of dirt or grease to be removed.—J. F. B.

Emulsions; Method of making — J. A. De Cew, Montreal, Canada. U.S. Pat. 1,317,617, 30.9.19. Appl., 25.2.18.

OIL is subdivided into fine particles by means of pressure within an atomising device and at the same time is brought into intimate contact with a warm alkaline solution, in which it is violently agitated. The emulsion thus produced is immediately discharged into an aqueous solution at a lower temperature, whereby a stable emulsion is formed.

—J. F. B.

Glycerin from liquids containing it; Process for obtaining pure — Farbentabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. (A) 303,805, 17.6.17, and (B) 305,174, 6.7.17.

(A) THE liquid is treated with lead compounds, such as litharge or lead hydroxide in order to precipitate an insoluble lead-glycerin compound. This is separated and decomposed by any suitable means, e.g., with hydrogen sulphide, sulphuric acid, or carbon dioxide. (B) The lead-glycerin compound

may be decomposed by heating with water under pressure. A solution containing 16% of glycerin is thus obtained; the lead oxide is precipitated in a heavy form and can be easily removed to serve for the precipitation of a further quantity of glycerin from crude glycerin or spent-wash.—J. F. B.

Glycerin; Process for obtaining pure — from glycerin-containing liquids. Farbentabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 305,175, 25.9.17. Addition to Ger. Pat. 303,805 (see preceding abstract).

LIQUIDS containing glycerin are treated with lead compounds in the presence of a small quantity of alkali either with or without the aid of heat.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Pigments for galvanised iron primers. H. A. Gardner. Paint Manufacturers' Assoc., U.S.A. Circ. No. 80. Dec., 1919. 2 pp.

EXPERIMENTS have shown that basic pigments in the presence of moisture rapidly etch the smooth surface of galvanised iron. This would indicate that much of the peeling trouble caused by non-adherence of paints to galvanised iron could be overcome by application of a priming paint containing substantial amounts of basic pigments, e.g., red lead and zinc oxide, ground in an oleaginous liquid containing sufficient water to render reactive the basic properties of such pigments.—A. de W.

[Drying] oils; Thickening of — F. Fritz. Chem. Umschau, 1919, 26, 199–200.

ON dissolving magnesium linolate in linseed oil at a temperature just sufficient to overcome foaming due to contained moisture, the solution remains liquid on cooling. If heated for a long time at 200°–250° C., or if the magnesium soap be produced by dissolving the metal in the oil at a necessarily high temperature, solidification takes place on cooling. Thus, for solidification to take place by the aid of magnesium soap, the polymerisation factor is also necessary. The increased coherence and accelerated solidification imparted to oxidised oil by previous solution of magnesium soap in the oil is advantageous to the properties of the end product used in the linoleum industry. For the purpose of increasing the thickness of heat-treated oils, the soap may be added either previous or subsequent to the heat treatment. The thickening properties given to linseed oil by magnesium soaps may be applied to the explanation of the "feeding" or "livering" of paints consisting of strongly heated oils and pigments containing basic constituents.—A. de W.

Gum shellac. C. H. Jones. Chem. and Met. Eng., 1919, 24, 715–721.

THE origin and native Indian method of preparation of shellac are described in some detail. In recent years machine methods have been introduced by one firm. The stick lac and grain lac are fed into mechanical grinders, and steam is used in the washing and melting processes, with the result that the time of production is greatly reduced and a more uniform shellac is obtained. In the native product the insoluble matter ranges from 14% in the finest grades to 5% in the lower grades, whilst in the machine-made product the insoluble matter never exceeds 0.5%, and may be as low as 0.2%. The qualities of orange shellac are determined princi-

pally by colour, and to a less extent by freedom from dirt, insoluble matter, and rosin. Average analyses of high-grade native shellacs gave the following results: Lac resin, 93–94; lac wax, 3–4.5; moisture, 1.5–2; and insol. matter (about two-thirds organic matter), 1–2%. Low-grade native shellacs contained: Lac resin, 91–93; lac wax, 3.5–4.5; moisture, 1.75–2.25; and insol. matter (about two-thirds organic matter), 2.5–4 or 5%. Average analyses of machine-made orange shellac gave: Lac resin, 95–96; lac wax, 3–4; moisture, 1.5–1.6; and insol. matter, 0.2–0.3%. Garnet lac contained: Lac resin, 97.7; lac wax, 0.5; moisture, 1.5–1.6; and insol. matter, 0.2–0.3%. A commercial sample of the best grade (D.C.) of shellac when treated with caustic alkali solution left a residual wax containing 82.18% C. and 14.25% H. This contained: Myricyl alcohol, 45; uncondensable acids (not oxy-acids) and impurities, 8.0; soluble and crystallisable oxy-acids, 27.0; and oily oxy-acids, only slightly soluble, 60.5%. Dry shellac for use in coating has been purchased for a long time by the U.S. Navy on the following general specifications:—*Orange gum shellac. Grade A quality.* (1) *For pattern and varnish work:* Must be equal in quality to the commercial brand "Double Triangle G," and capable of separation by hand. When treated with hot 95% alcohol the residue must not exceed 13%, and the shellac must be free from rosin and other adulterants. *Grade B quality.* (2) *For coating linoleum covered decks:* Must be of good quality and capable of separation by hand without the use of tools. The residue on treatment with hot 95% alcohol must not exceed 3%. It must be one of the following qualities: (1) Free from rosin and have an iodine value of less than 18 as determined by the method of the sub-committee on shellac analysis (this J., 1907, 1020); or (2) the grade known commercially as "U.S.A. A Standard TN" containing not more than 3% rosin. The grade known as "New York Standard 3%" will not be accepted. *Grade C quality.* (3) *Garnet lac for coating linoleum covered decks:* Must be of good quality and sufficiently finely ground to be readily soluble in alcohol. The residue from hot 95% alcohol must not exceed 1%. Must be free from rosin and have an iodine value of less than 18, as determined by the above-mentioned method. Somewhat different specifications are required when the shellac is to be subjected to electrical stress, or used for coating the interior of shells containing explosives. Certain samples which had been passed as suitable for the latter purpose were found to be quite unsuitable, as they showed a distinct acid test within 1 min., adhered badly to steel, and contained various metals, e.g., manganese, zinc, iron, aluminium, and calcium, in their ash (0.3 to 0.6%). They consisted of a poor grade of shellac, heavily loaded with rosin. Tests were made with various samples by coating the interior of experimental shells with a layer of the lacquer, charging the shells with nine typical explosives (including TNT, nitro-starch, picric acid, and ammonium nitrate) and leaving them for a week in an oven at 50° C. In each case with a good sample of shellac the film remained glossy and in good condition. The same results were obtained in experiments in which the shells were charged while hot. The following specifications have been worked out for pure shellac varnish: The varnish must be quite free from alkali, mineral acids, or volatile organic acids. The test is applied by shaking continuously for 10 mins. 20 grms. of the sample with 50 c.c. of neutral distilled water: if no change occurs in 3 mins. the amount of acid or alkali is negligible. The varnish must be free from heavy metallic oxides except traces of iron oxide, lime, or silica, and must contain no nitrocellulose or other nitrated material. It must adhere firmly, and when dry show a heavy, firm, tough, glossy coating, which will not crack,

peel, or flake. The varnish shall be mixed as follows: Shellac, 4lb. 1oz.; alcohol, 1 gall.; and turpentine, 1 pint. Shellac or garnet lac used in the above formula shall be finely ground so as to dissolve readily in alcohol. It shall not yield more than 1.75% of insoluble residue when treated with hot 95% alcohol. It must not contain rosin, and its iodine value must not exceed 18. The moisture must not exceed 1.75%, and the ash 1.5%. The alcohol in the formula must be either 188 proof completely denatured, or 190 proof specially denatured. The turpentine may be either a distillate from pine oleo-resins, or wood turpentine extracted from resinous woods. It must be colourless, have sp. gr. within the limits of 0.860–0.875 at 15.5° C., and initial b. pt. 150°–160° C. 90% must distil below 170° C., the polymerisation residue shall not exceed 2%, and its refractive index shall not be less than 1.500 at 15.5° C.—C. A. M.

Condensation products; Production of resinous — from phenols and formaldehyde. Chem. Fabr. K. Albert and L. Berend, Amöneburg. Ger. Pat. 301,374, 26.3.13.

FORMALDEHYDE, or compounds yielding formaldehyde, are treated with *m*-cresol or its higher homologues, either in presence or absence of condensing agents. *m*-Cresol has a reaction velocity equal to five times that of *o*- and *p*-cresol. The products are characterised by their bright colour, hardness, and freedom from smell. Both soluble and fusible, as well as insoluble and infusible resins are obtainable; the soluble variety most nearly resembles natural resins and is suitable for the manufacture of varnishes. The insoluble products are neutral and are therefore specially adapted for electro-technical purposes, and they are superior to condensation products hitherto prepared by means of acids and alkalis.—W. J. W.

Varnishes for printing ink for copper or zinc plates, lithographic stones or books. A. Kronstein, Karlsruhe. Ger. Pat. 302,544, 8.2.16.

Fish oil is subjected to a vacuum distillation, the amount which is distilled being governed by the special requirements. Thus for a thin varnish for copper plates 10% is sufficient, but for thicker varnishes the amount is 45%. A mixture of $\frac{1}{4}$ of thick varnish with $\frac{3}{4}$ of the thin quality gives good results. For lithographic and zinc printing 35–40% is distilled. The varnishes dry rapidly even without the use of siccatives.—W. J. W.

Nitrocellulose; Precipitation of — from organic solvents. Vereinigte Cöln-Rottweiler Pulverfabriken, Berlin. Ger. Pats. (A) 314,317, 6.6.18, and (B) 314,318, 21.8.18.

(A) Solutions of nitrocellulose in acetone or other solvent are diluted with water, after which an electrolyte, e.g., alum, is added, and the solutions are then intimately mixed with organic compounds which are insoluble in water and have a slight gelatinising action on nitrocellulose. Suitable compounds are toluol, xylol, aniline, methylaniline, dimethylaniline, carbon tetrachloride, pine needle oil, chloroform, and carbon bisulphide. The nitrocellulose is precipitated as a dense mass which can be readily mixed with the organic compounds, the resultant product being employed for the manufacture of varnishes or lacquers. (B) The boiling solvent is diluted with water, an electrolyte is then added, and heating is continued until the nitrocellulose settles out in the form of grains, which can easily be separated from the supernatant liquid. The yield may exceed 90% of the dissolved nitrocellulose. The

exploding point of the precipitated material is 180° C. or above.—W. J. W.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning liquors; Direct conversion of — into pulverulent solid extracts containing very little water. Smaic and Wladika. Gerber, 1919, 45, 189—191, 204—205.

TANNING liquors suffer decomposition when submitted to prolonged high temperatures even *in vacuo*. It is necessary to reduce the temperature and time of concentration to a minimum, and even then there is some alteration in the tannins themselves shown by the dark colour of the liquors and increased amount of insoluble matter. These difficulties are avoided in a process recently introduced for drying albumin, milk, gelatin, and other materials easily decomposed by heat. By means of compressed air the liquid to be concentrated is forced through fine orifices as a spray into a closed chamber from which the water vapour is continuously exhausted. The dried product falls on to the floor of the chamber and is automatically removed. A clarified oakwood extract containing tans 9.12%, non-tans 6.99%, water 83.45%, insoluble matter 0.44%, and ash 0.66%, when thus treated yielded a dry granular extract containing tans 50.51%, non-tans 39.91%, water 7.58%, insoluble

matter 1.97%, and ash 3.30%. Calculated according to the same percentage water basis, the liquor and extract are practically identical in composition. The extract dissolves very readily to a liquor of the same colour as the original, and the liquor does not give any sediment on standing. It is usually necessary to dry the solid extracts further.—D. W.

Tannin analysis; Modified method of —. Baldracco. J. Soc. Leather Trades Chem., 1919, 3, 197—198.

THE tannin solution is prepared according to the rules of the S.L.T.C. 30–35 c.c. of this solution is passed through a filter bell containing 8–10 grms. of lightly chromed hide powder. The wet powder is blown into a shaking bottle and shaken for 15 mins. with 70 c.c. of the tannin solution. The detanned solution is filtered first through cloth and then through folded filter paper without the customary addition of kaolin. 50 c.c. of the filtrate is evaporated as usual to determine non-tans. This method requires less time than the official method of analysis and gives identical results.—D. W.

Tannin analysis; Baldracco's modified method of —. J. G. Parker. J. Soc. Leather Trades Chem., 1919, 3, 199—200.

A NUMBER of tannin extracts have been analysed according to the S.L.T.C. shake method and also by Baldracco's modified method (see preceding abstract). A comparison of the results shows differences in the tannin determinations of 2%. The agreement is not so good as Baldracco claimed, and the new method does not appear to be more simple nor does it save time. It combines all the disadvantages of the present shake method and some of those of the old filter bell method.—D. W.

Alkali sulphide; Determination of — in dilute solution [lime liquors]. H. G. and W. G. Bennett. J. Soc. Leather Trades Chem., 1919, 3, 190—193.

A MEASURED quantity of the solution containing not more than 0.04% of hydrogen sulphide is distilled with an excess of boiling magnesium chloride solution in an atmosphere of carbon dioxide. A current of this gas carries the liberated hydrogen sulphide into a receiver containing 25 c.c. of N/10 iodine solution, and a second receiver containing 25 c.c. of N/10 sodium arsenite solution is arranged to trap any iodine vapour carried over. Where lime liquors are under investigation 2 c.c. of glacial acetic acid should previously be added to the iodine solution in the receiver to neutralise the ammonia which distils over. With these precautions and the absence of any rubber connections exposed to the iodine vapour, the method is very accurate.—D. W.

Hydrogen ion concentration of acid solutions [chrome tanning liquors]; Contrasting effects of chlorides and sulphates on the —. A. W. Thomas and M. E. Baldwin. J. Amer. Chem. Soc., 1919, 41, 1981—1990.

THE addition of sodium chloride or ammonium chloride to chrome tanning liquor increases the hydrogen ion concentration, whilst the addition of magnesium sulphate, sodium sulphate, or ammonium sulphate reduces it. Solutions of chromium sulphate, sulphuric acid (0.0005N and 0.1N), and hydrochloric acid (0.001N and 0.1N) behave similarly with both chlorides and sulphates. The power of increasing the hydrogen ion concentration follows the order:

—J. F. S.

Glue; Manufacture of — in the tropics from tannery refuse. K. C. Srinivasan. Dept. Industries, Madras, 1919. 28 pages.

WET fleshings were delimed, washed, and dried in

the sun, soaked for about an hour, transferred to new weak lime liquor, and delimed the next day. The delimed stock was placed in a loosely woven jute bag or rattan basket, and suspended in water in a copper pan over an open fire which was maintained at a low, steady heat. The fleshings were quickly exhausted, and in about an hour were reduced to small bulk. The thin liquor showed excellent adhesive properties. It was filtered and concentrated in the copper pan, being vigorously stirred and just kept at a gentle simmer. When a strength of above 45° Bark. had been attained at a temperature of 50° C., the liquor was poured into shallow galvanised-iron trays lightly coated with linseed oil or a mixture of linseed oil and kerosene. The solution was removed next morning to a refrigerator working at about -7° C. For factory purposes a strongly made hollander is necessary to tear up the soaked fleshings into shreds, a mechanical cleaner to free them from lime and dirt, direct steam digesters, clarifying vats with linen filters, and a vacuum evaporator. The jelly is dried in a roomy building fitted with racks. A powerful fan drives the air through a screen of steam-pipes, thus maintaining a temperature of 31.5° C., and the time required for drying varies from ten days to two months. Experiments showed that undried fleshings were unsuitable for the manufacture of glue, and that there was a deterioration in the yield and quality the longer the fleshings had been stored. The raw material was found to be highly adulterated, and required purification from all foreign matter before being digested. The yield of dry glue from 1000 lb. of raw material varied from 125 to 170 lb. Liming has no good influence on the quality or quantity of the glue, although limed fleshings are more quickly digested than unlimed ones. The total number of hours of soaking necessary is approximately $H = 48 - 4(T_1 - 28^\circ \text{C.}) + 2(28^\circ \text{C.} - T_2)$ where T_1 is the maximum and T_2 the minimum temperature during the day. Particulars are given of the machinery required and the working costs.—D. W.

Casein; Proximate analysis of commercial —. F. L. Browne. J. Ind. Eng. Chem., 1919, 11, 1019—1024.

To ascertain the suitability of commercial casein for making waterproof glues, it is suggested that determinations be made of the fineness, moisture, ash, fat, nitrogen, and acidity; the colour and odour of the sample are also taken into account. Analyses of some 200 samples are recorded. The moisture is determined by drying *in vacuo* at 70°—80° C. To determine acidity, 1 gm. of the sample is dissolved in 25 c.c. of N/10 sodium hydroxide, the solution then diluted with 100 c.c. of water, and titrated with N/10 acid, using phenolphthalein as indicator. The acidity is expressed as c.c. of N/10 alkali used by 1 gm. of dry, fat-free and ash-free substance. U.S. specifications require that all casein used for making waterproof glue for use in aeroplanes should pass the following tests:—Colour, white or light cream; odour, very slight; moisture, not more than 10%; fat, not more than 1%; ash, not more than 4%; nitrogen, not less than 14.25%; acidity, not more than 10.5 c.c. of N/10 alkali solution per gm.—W. P. S.

Red pea gall. Nierenstein. See IV.

Tanning process. J. M. Brown, Austin, Ark. U.S. Pat. 1,323,956, 2.12.19. Appl., 4.4.19.

In a quantity of water sufficient to cover a hide, cutch is dissolved in the proportion of 1 lb. to 10 lb. of hide. The hide is dipped into the solution at successive intervals, a quantity of white vitriol

(zinc sulphate) equal to one-half the weight of the cutch is added, and the hide is returned to the solution until completely tanned.

Iron-tanned leather; Manufacture of tough and durable —. K. W. Mensing, Freiberg. Ger. Pat. 314,487, 28.11.15.

TANNING with iron salts is carried out in presence of an oxidising agent in excess. During preparation of the iron solution the temperature must not exceed 35° C., and the solution should be rapidly cooled to normal temperature. Treatment with the solution should then proceed at once. The delimed hide may be treated with faintly alkaline salts or with basic aluminium and chromium oxides, and then tanned with slightly acid ferric salts. The deleterious effect of ferrous salts in the tanning bath, and their ultimate appearance in the leather, are thus avoided, and in addition the hydrolytic decomposition of the ferric salts is prevented.—W. J. W.

XVI.—SOILS; FERTILISERS.

Soils; Carbonation of burnt lime in —. W. H. MacIntire. Soil Sci., 1919, 7, 325—453.

NEITHER calcium oxide nor hydroxide when perfectly dry reacts with dry carbon dioxide, but a very slight film of moisture on the containing vessel is sufficient to start the action. The oxide, when exposed in small amounts to a humid atmosphere, undergoes carbonation more rapidly than does the hydroxide prepared from it or from which it is prepared by ignition, under similar conditions of exposure. The formation of carbonate from the hydrated oxide is controlled by the amount of free water available to convert the hydrate from solid to solution phase. The carbonation of quicklime must be preceded by its hydration and solution, but when moist carbon dioxide is present the reactions are so rapid that they may be considered as simultaneous. There is a tendency for a protecting film of calcium carbonate to form round nuclei of the hydrate and thus to check further carbonation during exposure to air. Pot and fields trials indicate that lime is carbonated more rapidly when distributed on the surface of the soil than when in a dry soil mulch or in a moist soil. A sand mulch above the soil tends to retard carbonation. After the application of 2 tons of burnt lime or of hydrated lime per acre to the top six inches of a soil maximum carbonation was reached in six days and complete absorption of the lime by the soil in ten days. The addition of water hastened both the carbonation and the absorption. The time required for maximum carbonation was not affected by the presence of 48 tons of dry farmyard manure per acre. Where, however, heavier dressings (8 tons per acre) of lime were applied maximum carbonation (up to 96% of theory) of the unabsorbed lime occurred after a period of 19—38 days, the time required being unaltered by the presence of dry manure. Whilst with small or medium dressings of lime the carbonation was rapid, with large dressings, such as 32 or 100 tons per acre, carbonation proceeded more slowly, reaching about 80% of theory for the 32-ton dressing and about 50% of theory for the 100-ton dressing by the end of the second year, after which little definite change was recorded. The losses, by leaching, of calcium salts from a soil to which chalk was applied were practically independent of the extent of the treatment, but where quicklime was applied they increased with the weight of lime applied. With a soil *in situ* the presence of the subsoil very considerably checked this loss by leaching. In a comparison of a clay loam and a silt loam, it is shown that, for the former type of soil, the addition of water to

the soil caused a more rapid and greater ultimate carbonation of lime than was attained in the air-dry mixture both in the case of surface applications and when the lime was mixed with the soil. The reverse holds, however, for the silt loam. Experiments in which hydrated lime was applied to the surface of a soil-mulch or in special containers, having open ends, in the soil, the soil being in cylinders with either solid or perforated bottoms, indicate that, whilst the carbon dioxide in the soil atmosphere plays some part in the carbonation, the main action is due to atmospheric carbon dioxide. The principal action of the soil atmosphere is due to its moisture. This was confirmed by experiments in which trap layers of hydrated lime were placed between the moist soil surface and the overlying surface charges of calcium hydroxide. More extensive carbonation occurred in open sandy types of soil than in the heavier types, although the latter were richer in organic matter. This is probably due to less absorption of the lime in the open sandy soils. The practical conclusions drawn from this detailed study of the carbonation of lime are as follows:—Quicklime or hydrated lime, when applied at the rate of 2–4 tons per acre will revert to the carbonate more rapidly when left on the soil surface than when mixed with a dry mulch or the moist soil, the reversion being most rapid during humid atmospheric conditions. If a dressing of the oxide or hydrate is left on the surface of the soil for several days prior to incorporation, the treatment is in effect equivalent to an application of finely divided chalk. If the oxide or hydrate is incorporated with the top layer of soil, prior to a more thorough dissemination throughout the soil, the concentration may be sufficient to effect a temporary, partial sterilisation in that layer, which may have beneficial results. The first action of the quicklime applied to the soil is to fix atmospheric or soil moisture and there is no indication, when this is completed, of any tendency to cause chemical disintegration of soil organic matter. Neither burnt nor hydrated lime, when applied in the amounts commonly used in practice, can be considered as chemically destructive of soil organic matter.—W. G.

Soil acidity, the resultant of chemical phenomena.
H. A. Noyes. *J. Ind. Eng. Chem.*, 1919, 11, 1040–1049.

THE author holds that chemical reactions are the cause of the acidity of soils and of the changes brought about by the addition of substances such as carbon dioxide, calcium carbonate, phosphates, and nitrogenous fertilisers. The reaction of a soil at any time depends on the nature of and the proportions in which the constituents are present with water. Change in the water content, removal of substances from solution, and the addition of other substances alter the reaction in accordance with the law of mass action.—W. P. S.

Potassium in soils; Use of nickel crucibles for the Lawrence Smith fusion in determining —.
S. S. Walker. *J. Ind. Eng. Chem.*, 1919, 11, 1139–1140.

NICKEL crucibles may be substituted for platinum crucibles in carrying out the fusion of the soil with ammonium chloride and calcium carbonate; the same results are obtained but, as the nickel is attacked by the fusion mixture, the crucibles do not last long.—W. P. S.

Humic [peaty] soil; Hysteresis of aqueous solutions of —. H. Puchner. *Kolloid-Zeits.*, 1919, 25, 196–208.

A CLEAR dark yellow solution is obtained by treat-

ing peat with cold water, and at the same time a faintly acid aromatic odour is noted. The solution has an acid reaction and on keeping deposits a slimy brown substance and the solution becomes alkaline. The deposit obtained from the solution obtained from 50 grms. of peat amounts to 0.490 gm. and on incinerating leaves a residue of 0.218 gm. The ignited residue contained alumina, ferric oxide, manganese oxides, lime, magnesia, and alkalis, sulphate, phosphate, and silicate. Microscopical examination of the deposit and the solution showed that on keeping changes occurred in their appearance, notably the formation of crystals. The clear solution after sedimentation contains gels of silicic acid, ferric hydroxide, and alumina.—J. F. S.

Carbon dioxide fertiliser; Use of blast-furnace waste gases as —. F. Ruedel. *Stahl u. Eisen*, 1919, 39, 1497–1506.

CARBON and water form the main constituents of plant substances, and the former is obtained by assimilation of atmospheric carbon dioxide. The partial pressure of this is normally very small—say, 0.03%—and so may prove the limiting factor at periods of rapid growth when the supply of moisture and mineral fertilisers is ample. It has been shown by Kreusler (1885) that the rate of assimilation of carbon dioxide increases extremely rapidly with the partial pressure until this reaches about 0.5%, but afterwards little effect is produced by further increase. This has been examined in horticultural trials in which plants were grown in an atmosphere enriched in carbon dioxide by the exhaust gases of large gas engines. These were driven by blast-furnace gas; the cleaning necessary to render the gas suitable for use in gas engines also removed plant poisons. In 1917 identical crops were grown in three glasshouses 25 m. × 6 m. each, two of them being supplied with exhaust gas, and the third used as a control with a normal atmosphere. Diluted exhaust gas was led in through perforated pipes placed under the roof so as to raise the partial pressure of carbon dioxide to about 0.5%. The experiment began in June, and at once the treated plants obviously grew more vigorously. The deeper shade of green in the foliage of the treated plants pointed to a more rapid production of chlorophyll. The crops were much increased as compared with those of the plants in the control house, e.g., the tomato crop was 2½ times and cucumber crop 1½ times greater. Analogous results were obtained in open-air experiments in which a plot was divided into squares by a network of perforated pipes, through which exhaust gases were discharged at ground level. A variety of vegetables showed increased crops as compared with a control crop—the ratio of increase reaching 2.9 times. In 1918 the trials were repeated with similar results. Three additional glasshouses 40 m. long were used, and the open air trials were made on a field 30,000 sq. m. in area divided up by pipes as before. It was found that the effects of the treatment are more evident when the land is otherwise well fertilised, indicating that the carbon dioxide promotes efficient utilisation of other manures. Analytical determinations on the atmosphere of a glasshouse during the treatment revealed the rapid absorption of carbon dioxide by the plants. In discussing the economic importance of carbon dioxide fertilisation, it is pointed out that a blast-furnace plant of 1000 tons daily output of iron yields carbon dioxide sufficient for 4000 tons of potatoes.—H. J. H.

PATENT.

Fertiliser and process of making same. G. H. Earp-Thomas, Glen Ridge, N.J. U.S. Pat. 1,309,723, 15.7.19. Appl., 10.4.17.

Finely divided raw phosphate rock is mixed with a humus material containing nitro-bacteria, which exert a decomposing action on the rock.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Clarification [of sugar juice]; Some temperature experiments in —. H. S. Walker. Int. Sugar J., 1919, 21, 611—613.

DURING the suspension of work at the week-end in a factory in Hawaii it was observed that the limed juice in the settling tanks decreased in purity to a marked extent (1° per hour) at 190° — 212° F. (88° — 100° C.), whereas at a lower temperature, viz., about 180° F. (82° C.), the value remained practically constant. The loss of sucrose at the higher temperature is due, not to the presence of heat-resisting micro-organisms, as was at first presumed, but to the effect of heat under the conditions prevailing.—J. P. O.

Scums; Influence of the duration of contact of the — with the first saturated juice in beet sugar manufacture. V. Stanek. Z. Zuckerind. Böhm., 1918, 42, 417—423.

LABORATORY and factory experiments are described demonstrating that instead of immediately filtering off the juice after its first carbonation it is advantageous to stir it for about 30 mins. at 85° C. A marked improvement in the rate of filtration results, and the purity of the juice is raised (e.g., from 93.3 to 94.1), while no increase in calcium oxide, mineral matter, alkalinity, or colour could be observed. It is suggested that during the time of contact amorphous calcium carbonate is converted into the crystalline form, and that tricalcium saccharate present is decomposed with the liberation of sugar.—J. P. O.

Sugar dryers; Method of increasing the capacity of —. E. V. Anthonijs. Archief Suikerind. Nederl.-Indië, 1919, 27, 1125. Int. Sugar J., 1919, 21, 622.

AFTER centrifuging the sugar, and washing with water, it is treated with superheated steam at about 250° C. while still in the machines. This hot sugar may subsequently be passed much more rapidly through the dryers than in the usual mode of operating; moreover, it is unnecessary to circulate a current of heated air through the drying drum.—J. P. O.

Cane sugar; Sucrose content of the molasses as an index of the inversion occurring during the manufacture of —. F. I. Seard. Int. Sugar J., 1919, 21, 604—605.

It is characteristic of the juice produced from cane in British Guiana that its reducing sugars are optically inactive, though this is seldom so in the case of juice obtained in other countries. In order, therefore, to obtain an indication of the amount of reducing sugars resulting from the inversion of sucrose during manufacture, it is suggested that a comparison should be made between the sucrose determined by direct polarisation and that found by the reduction of Fehling's solution before and after hydrolysis. The first figure should be lower than the second in proportion to the amount of levo-rotatory reducing sugars which may have formed during clarification, evaporation, and crystallisation. Normal lead acetate must be used for the clarification of the solution for polarisation, since the basic salt precipitates levulose and dex-

trose (compare, however, Davis, this J., 1916, 203). Application of this method has shown that in the manufacture of raw sugar under good conditions in Guiana no indication of inversion is obtained; whilst in the production of yellow Demerara sugar (in which the juice is generally treated with phosphoric acid to slight acidity), it is very small, seldom more than 2% of the sucrose present being hydrolysed.—J. P. O.

Sugar grain in final cane molasses; its origin and determination. H. Kalshoven. Archief Suikerind. Nederl.-Indië, 1919, 27, 1560—1664. Int. Sugar J., 1919, 21, 608—610.

MOST cane factory molasses contains fine sucrose crystals, averaging about 8%, a quantity that represented in the case of the last Java crop about 35,000 tons of commercial sugar. Probably the principal cause of its presence is the formation of "false grain" during boiling in the vacuum pan, though some may result from centrifuging at a high temperature (say 50° C.), further crystallisation occurring on the subsequent cooling of the molasses. Some may also be produced by cooling massecuite in crystallisers in which the entire contents do not come under the influence of the stirrers, "dead corners" being formed. Its amount may be determined by ascertaining the refractive index of the molasses before and after diluting with a sufficient amount of water to dissolve the fine grain, the first reading giving the solids of the molasses alone (the presence of the crystals not affecting the result), and the second that of the molasses plus crystals.—J. P. O.

Syrups and molasses; Standards for differentiating between American table —. W. L. Owen. La. Planter, 1919, 62, No. 15, 235—236. Int. Sugar J., 1919, 21, 622.

It is difficult, if not impossible, to establish analytical standards differentiating between syrup, first molasses, second molasses, and third molasses as produced in Louisiana. Generally the sucrose in the syrup (concentrated cane juice) varies from 49 to 62; in first molasses from 38 to 54; in second molasses from 28 to 45; and in third molasses from 23 to 33%. In the case of the purity coefficient the differences for the four classes of products are 70 to 87, 43 to 73, 35 to 60, 30 to 50 respectively; while the maximum figures for ash are 2.5, 9.0, 10.6, and 12.5%.—J. P. O.

Reducing sugars; Ost's copper potassium carbonate solution as a reagent for the determination of —. P. Beyersdorfer. Z. Ver. deut. Zuckerind., 1919, 403—437.

COMPARED with Fehling's solution, the author regards Ost's solution (this J., 1895, 993) as superior in most respects for the determination of reducing sugars. It is more sensitive, being capable of detecting 1 mgrm. of invert sugar in the presence of 10 grms. of sucrose, against 5 mgrms. by Fehling's solution. Its effect upon sucrose in producing reducing substances is appreciably less, 3.8 mgrms. of copper being obtained as against 30 mgrms. Moreover, 1 equivalent of invert sugar reduces 3 of copper compared with 2 in the case of Fehling's solution. Ost's solution is prepared by dissolving 250 grms. of potassium carbonate and 100 grms. of potassium bicarbonate in about 700 c.c. of water in a litre flask, which is heated in a water-bath at 60° — 80° C. After cooling, a solution containing the desired amount of pure copper sulphate is added in small successive amounts while well agitating, the liquid being then made up to the mark, mixed, and filtered. Two solutions should be prepared—the first containing 4 grms. of copper (15.71 grms. of crystallised copper sulphate) per litre, which is used for general purposes; and the second with only

0.8 grm. of copper (3.14 grms. of copper sulphate), which serves for the examination of products, as those of the refinery, in which a small amount of invert sugar is present with a large proportion of sucrose. This weaker solution is more sensitive than one of higher copper content, and attacks sucrose less. It may be prepared from the stronger liquor by mixing one volume of the latter with 4 of a filtered solution containing 250 grms. of potassium carbonate and 100 grms. of potassium bicarbonate per litre. For the determination of the cupric-reducing power, 75 c.c. of Ost's solution is mixed with 50 c.c. of the sugar solution in a 125 c.c. flask, and the volume adjusted to the mark. Heating is carried out in a boiling water bath for 15 and 20 minutes for the strong and the weak liquors respectively, and at the end of the period the amount of cuprous oxide precipitated is determined by Bertrand's method (this J., 1907, 60) of dissolving the precipitate in an acid solution of a ferric salt and titrating with permanganate, a procedure which is considered to be capable of yielding very reliable results (*cf.* this J., 1919, 381 A). The amount of invert sugar corresponding to the amount of copper reduced is calculated from two tables. The first is for use with the "fifth normal" liquor, when the 50 c.c. of sugar solution taken for the determination contains less than 20 mgrms. of invert sugar in the presence of 10 grms. of sucrose (for application in the case of refinery products); while the second is applied when the "normal" solution is used, the limit of invert sugar present in the 50 c.c. of sugar solution being 2 to 100 mgrms., and that of sucrose 0 to 10 grms.—J. P. O.

Sugars; Titration of —. E. Schowalter. Z. Unters. Nahr. Genussm., 1919, 38, 221—227.

THE method described by Rupp and Lehmann (this J., 1919, 691 A) is criticised and considered to be untrustworthy under the conditions prescribed.
—W. P. S.

Dextrose and levulose; Separation of —. F. Lucius. Z. Unters. Nahr. Genussm., 1919, 38, 177—185.

WHEN a 2—4% dextrose or levulose solution is heated for seven hours with the addition of hydrochloric acid, the optical rotation of the dextrose is not affected, whilst that of the levulose is destroyed completely. The levulose is converted into other reducing substances, and, consequently, the remaining dextrose cannot be determined by finding the reducing power of the solution after treatment, but polarisation gives an accurate measure of the latter sugar. The details of the determination are as follows: 50 c.c. of the sugar solution is mixed with 10 c.c. of 5N hydrochloric acid and heated for seven hours in a boiling water bath; the mixture is then nearly neutralised with 5N sodium hydroxide solution, diluted to 100 c.c., and polarised at 20° C. in a 200 mm. tube. If necessary, the solution is treated with animal charcoal before it is polarised. The method may be used for the determination of dextrose in invert sugar etc. If the heating is prolonged for 10 to 12 hrs. the rotation of the dextrose itself begins to decrease slightly.—W. P. S.

Sugars; Conversion of the simple — into their enolic and ethylene oxide forms. E. F. Armstrong and T. P. Hilditch. Chem. Soc. Trans., 1919, 115, 1410—1428.

ALTHOUGH α - and β -glucose (dextrose) are practically unaffected by permanganate in pure neutral solution, on the addition of acid or alkali, reduction sets in at once at a definite rate under definite conditions. The change with acids is instantaneous, but with alkalis it is more gradual as the reducing power increases within limits the longer the alkali has acted. The same facts are true as regards fructose (levulose) and mannose, though the rates of reduc-

tion differ, being greater than that of glucose in acid solution; in alkaline solution the order is fructose, glucose, mannose. It is considered that the active agent in acid solution is the ethylene oxide modification of the sugar, whilst in alkaline solution it is most probably the enol which is gradually produced. Parallel reducing actions are observed with methylene blue and indigo, and it is noteworthy that in similar experiments with simple aldehydes, ethylene oxide, and epichlorhydrin, the ethylene oxides behave similarly to the sugars in acid solutions, and the aldehydes in alkaline solutions both towards methylene blue and permanganate.—G. XVIII.—FERMENTATION INDUSTRIES.

Moisture in malt; Determination of —. T. J. Ward. J. Inst. Brew., 1919, 25, 335—352.

IS the Institute of Brewing method for determining moisture in malt (this J., 1906, 236) the conditions are not defined with sufficient completeness to ensure concordant results. The method recently adopted for moisture determinations in barley (this J., 1918, 523 A) is much more satisfactory in this respect, and may be applied to malt in the following modified form:—15—20 grms. of the well-mixed sample is finely ground in a coffee-mill; the first third of the grist is rejected, and from the remainder 5 grms. is immediately weighed out into a counterpoised flat-bottomed dish provided with a well-fitting lid, and placed on the floor of a boiling-water oven, with the lid beside it or on the shelf. After drying for 3—3½ hours, the dish is stoppered, transferred to a desiccator, and weighed when quite cold. The author describes an exhaustive investigation of the influence of various factors on the results, the experiments being made with the usual type of cubical water-jacketed oven having a shutter ventilator in the lower part of the door and an open ventilator at the top. The chief conclusions are as follows:—Accurate results may be obtained with ovens of any capacity between 3½ and 33 litres. The amount of water in the jacket is immaterial, provided its level remains higher than the interior floor of the oven, and it is kept boiling briskly throughout the drying process. Unsuspected leaks through which water or steam may escape from the jacket into the oven may cause consistently low results. Such leaks are detected by allowing the oven to stand overnight with the jacket full of water, and afterwards examining the interior for drops of water. Both ventilators must remain open during determinations; the total area of the openings in the lower ventilator, in sq. cm., may vary from 1/850 to 1/19000 of the capacity of the oven, in c.c., without affecting the results. There is no objection to the presence of a shelf in the oven, provided it is perforated with at least four holes of diam. about 1 cm.; but as the temperature on the shelf is always considerably below 100° C. (*e.g.*, 90° when the lower ventilator is open and 94° C. when it is closed), the dishes containing malt must always be placed on the floor, and not within a radius of 5 cm. from the ventilator. The dishes

used may be of glass, porcelain, aluminium, tin-plate, etc., but should be flat-bottomed, with vertical sides, and with well-fitting lids, so that a closed dish containing dried malt may be left exposed to the open air of a laboratory for an hour without gaining more than 1 mgrm. in weight. Ordinary shallow tins with well-fitting lids have proved very satisfactory. The average depth of malt in the dishes should not exceed 5 mm. The same results are obtained whether the malt is finely or coarsely ground. A delay of 5 mins., however, between grinding and weighing out may cause a perceptible error (e.g., 0.1%) owing to absorption of moisture. No error is caused by weighing out incorrect proportions of the husk and endosperm fractions of the grist, for these do not differ much in moisture-content and affinity for moisture. Any number of samples may be dried on the floor of the oven at the same time, but no other material should be present, and the oven door should not be opened, especially after the first hour. The same results are obtained at 100° C. whether drying is continued for three hours or longer—e.g., 18 hours; but at 105° constant weight cannot be attained within a reasonable time. The relative humidity of the atmosphere, unless above 96%, does not affect the results; but the entry of moist fumes from the gas-burner into the ventilator must be prevented—e.g., by means of a guard-plate extending downwards from the bottom of the front of the oven. By observing the precautions indicated above, the experimental error in determining the moisture in malt may be reduced to $\pm 0.02\%$.—J. H. L.

Malts; Some analyses of barleys and of the —
made from them. A. R. Ling. J. Inst. Brew.,
1919, 25, 288-296.

ANALYSES (see table) were carried out on various barleys and malts prepared therefrom in 1912-13.

a fair sample, but contained an abnormal proportion of damaged and extraneous corns. The malts from all the foreign barleys showed uneven germination, particularly that from the Polish barley, which was probably a mixture derived from more than one harvest. For the determination of starch in the samples Ewers' method (this J., 1908, 238) was employed, and the results are therefore probably high, owing to the presence of pentosans and other substances which yield sugars on hydrolysis with acid.—J. H. L.

Acidity of worts, beers, and other similar liquids; New methods for determining the —.
W. Windisch and W. Dietrich. Wech. Bran.,
1919, 36, 189-190, 201-203, 209-211.

SOME preliminary experiments were made to explore the practicability of determining the acidity of worts by Traube and Somogyi's method (this J. 1915, 511)—viz., by measuring the surface tension of the wort relative to that of water with a viscostagonometer, then adding a capillary inactive salt of a capillary active fatty acid, whereby the surface tension of the wort is diminished owing to the liberation of free fatty acid equivalent to the wort acidity, and finally determining the volume of standard alkali required to restore the original surface tension—i.e., to neutralise the liberated acid. In studying the change of surface tension accompanying the progressive neutralisation of solutions of various fatty acids, it was found that with nonylic, decylic, and undecylic acids the value of the surface tension constitutes as sensitive an indicator as litmus or neutral red in the region of their colour change. In applying the method to worts, the acidity of which is largely due to primary phosphates, salts of undecylic acid appear far preferable to valerates

* Contained 5% of damaged and idle corns and 3% of extraneous corns. † Contained 4% of damaged and idle corns.

With the exception of the Californian and Damascus barleys, all the barleys were of first grade, and required no special treatment in the malt-house. The English barleys were of the 1912 harvest, and gave excellent malts, showing very uniform germination. The Californian barley was

(loc. cit.), as the latter are scarcely affected by primary phosphate acidity. The method would have the advantage of being independent of the colour of a wort, but its accuracy becomes less the higher the surface tension of the wort.

—J. H. L.

Beer; Concentration of hydrogen ions in —. F. Ensländer. Z. ges. Brauw., 1919, 42, 127—130, 135—137. (See also this J., 1914, 212.)

The optimal hydriion concentration for the fermentative action of brewers' yeast is $p_H=4.76-4.16$, whilst for other yeasts investigated by the author the optimal reactions were found to be much more alkaline. In unfermented brewery worts the hydriion concentration is about $p_H=6.5-5.5$, but owing to the formation of acids during fermentation the average value for dark beers made with waters fairly rich in carbonates is $p_H=4.5$ and that for pale beers made with gypscous waters is $p_H=4.2$. Under normal circumstances, therefore, the yeast raises the hydriion concentration of wort to approximately the value most favourable to its own fermentative activity. Any circumstance which tends to prevent or delay the attainment of this optimal hydriion concentration in the fermenting wort, e.g., the use of abnormally alkaline waters, low fermentation temperatures, or too little yeast, must accordingly favour the activities of foreign yeasts, since these thrive best in presence of relatively low hydriion concentrations.—J. H. L.

Fermentations; Production of bouquet in primary and secondary —. P. Lindner. Woch. Brau., 1919, 36, 223—224.

In wines naturally lacking in *bouquet* it appears possible to remedy this defect by the use of suitable kinds of pressed yeast in the secondary fermentation. Certain distillery yeasts, beer yeasts, and mycoderma yeasts, which produce fragrant odours during fermentation might be used. The production of *bouquet* depends more on the yeast employed than on the nutritive substances present, but it is intensified under certain conditions, e.g., when nitrogenous nutriment is lacking and growth is stimulated by high temperatures or other means. Lack of assimilable nitrogen leads to the degradation of yeast proteins, and the amino-acids formed are in part converted into higher alcohols which contribute to the production of *bouquet*. This accounts for the fragrant aroma frequently observed when brewing yeast is regenerated by growth in sugar solution, accompanied by aeration, the nitrogen-content of the yeast undergoing a considerable reduction. The removal of assimilable nitrogen by the yeast in the primary fermentation of wines, no doubt contributes to the production of *bouquet* during the secondary fermentation.—J. H. L.

Yeast as it occurs in nature. A. Jørgensen. J. Inst. Brew., 1919, 25, 353—355.

YEAST as it occurs in nature possesses the flocculating character, the cells tending to remain attached to one another in chains or aggregates. The contrary behaviour of certain yeasts employed in industry, the cells of which tend to separate and remain suspended in the surrounding liquid, thus causing difficulties in clarification, is a character acquired as the result of continued cultivation under artificial conditions. This acquired character can be entirely eliminated, whether in brewers', distillers', bakers', or wine yeasts, by "methodically cultivating the growth under the same conditions as those which it met during the greater part of the year while living in the state of nature." Further particulars will be published after the completion of more extended experiments.—J. H. L.

Yeasts; Formation of fat in — on solid media. P. Lindner and T. Unger. Z. techn. Biol., 1919, No. 1. Woch. Brau., 1919, 36, 188.

SUSPENSIONS of various brewery and distillery yeasts, spread over glass plates, were exposed to vapours of ethyl alcohol. An abnormally copious production of fat globules ensued in the yeast cells, and it is suggested that the formation of similar

globules, often observed in the superficial cells of yeast cultures on solid media, are due to the influence of alcohol vapour produced by the underlying cells. The fat is probably not a reserve material, for it is found in cells of very old cultures. Fat globules are found in largest numbers in cultures of bottom fermentation beer yeasts, whilst in cultures of top fermentation yeasts and wine yeasts the cell-contents tend rather to assume a granular appearance. The original paper contains a tabular record of the microscopical appearance of cultures of numerous yeasts in the V.L.B. collection in Berlin.—J. H. L.

Yeast; Autolysis of — in its dependence on hydrogen and hydroxyl ions. K. G. Dornby. Med. K. Vetensk. Nobelinst., 1918, 3, No. 23, 1—26.

THE simple yeast cell contains enzymes which are capable of degrading albuminous substances and are analogous in type with those present in animal organs. The enzymes identified are yeast pepsin, which degrades albuminous substances to peptones and has a maximum activity at the hydrogen ion concentration $p_H=4-4.15$; yeast trypsin, which does not attack yeast albumin, but attacks gelatin, casein, Witte-peptone, and similar substances, and has a maximum activity at $p_H=7.0$; yeast ereptase, which degrades polypeptides to amino-acids and has a maximum activity at $p_H=7.8$. The autolysis of yeast is brought about by these enzymes and consists in a successive degradation of albumin; it can only proceed when the different enzymes can operate simultaneously. The best hydrogen ion concentration for the process is $p_H=6.1$.—J. F. S.

Lactic acid bacteria; Acidity relations of —. O. Svanberg. Med. K. Vetensk. Nobelinst., 1919, 5, No. 2, 1—10.

Streptococcus lactis will raise the hydrogen ion concentration of milk and whey to $p_H=4.0$ at 16°C . *Bacterium casei* in milk and wort raises the hydrogen ion concentration to $p_H=3.05$. In the presence of sodium lactate the acidity which *Streptococcus lactis* can develop in milk is reduced proportionally to the lactate concentration. The acid tolerance of *Streptococcus lactis* towards sulphuric, hydrochloric, and phosphoric acids is the same, namely $p_H=3.4$ at 18°C ., and for *Bacterium casei* at 35°C . the value is $p_H=3.0$ for hydrochloric and phosphoric acids. The alkali tolerance for *Streptococcus lactis* at 18°C . is $p_H=8.0$.—J. F. S.

Enzyme action. Urease and the radiation theory of —. H. P. Barendrecht. Proc. K. Akad. Wetensch., 1919, 22, 126—138.

THE enzyme urease acts by radiation, which is only absorbed by its substrate, urea, and by hydrogen ions. This action is represented by the formula $nc/0.134 \log \frac{1}{(1-y)+ay} = mt$ in which a is the initial concentration of the urea, y the fraction present at time t , n the absorption coefficient of the hydrogen ions, m a constant, and c the concentration of the hydrogen ions. This explains the kinetics of urease action in both acid and alkaline solutions. In acid solutions a logarithmic curve is obtained and in alkaline solutions a straight line graph. When the urease is decaying the reaction may be reversed and urea synthesised from ammonium carbonate. (See also J. Chem. Soc., 1920, i., 195.) —J. F. S.

Residues containing carbohydrates; Method of treatment of — J. Effront, Brussels, and A. Boidin, Paris. Eng. Pat. 122,405, 2.1.19. (Appl. 131/19.) Int. Conv., 17.1.18.

AMYLACEOUS residues from the starch, brewing, or oil industries are utilised for the preparation of products which can be employed in brewing and in the manufacture of sweets and syrups. The residues are subjected, in slightly alkaline mashies, to the action of bacterial diastatic enzymes of the kind described in Eng. Pat. 16,198/14 (see Fr. Pat. 471,546; this J., 1915, 444), which are more powerful than vegetable diastase and act best in alkaline media. According to the character of the starch conversion desired, the mash may be held at temperatures ranging from 70° to 85° C. for $\frac{1}{2}$ —1 hour, after which saccharification is arrested, the mash filtered, and the filtrate concentrated to a syrup. From the residues from starch factories syrups may be prepared which crystallise to a mass containing 70% of dextrins (not coloured by iodine) and 30% of sugars, and which have the flavour of honey.

XIXA.—FOODS.

Milk; Carbonic acid and carbonates in cow's — L. L. Van Slyke and J. C. Baker. J. Biol. Chem., 1919, 40, 335—344.

THE carbon dioxide of milk may be estimated by the process originally proposed for the estimation of carbon dioxide in blood plasma (Van Slyke, this J., 1917, 944). Milk is drawn from the cow's udder into a 100 c.c. cylinder so as to fill the cylinder from the bottom upward, thus avoiding mixing with air or loss of carbon dioxide. 2 c.c. of this milk is transferred with precautions against loss of CO₂ into the Van Slyke CO₂ apparatus and treated with a 20% solution of lactic acid. This is found a more satisfactory method of liberating the carbon dioxide than by employing sulphuric acid, which clots the milk into large lumps. The carbon dioxide content of milk varies over a wide range; a normal value is regarded as about 10% by volume. The degree of acidity tends to decrease with an increase of carbon dioxide. The carbon dioxide may be completely removed by exhaustion from a thin film of milk which is kept in motion. After pasteurisation the carbon dioxide content of the milk falls, but the hydrogen ion concentration remains the same. The suggestion is advanced that the carbon dioxide content of milk might afford a means of distinguishing heated from normal milk. Probably the carbon dioxide of milk is present as a mixture of 1 part of carbonic acid to 2 of sodium bicarbonate.—J. C. D.

Milk; Conditions causing variation in reaction of freshly drawn — L. L. Van Slyke and J. C. Baker. J. Biol. Chem., 1919, 40, 345—355.

In over 300 samples of fresh milk the value of pH

varied from 6.50 to 7.20, being under 6.76 in 80% of the samples. In the case of 20 cows it was found that the reaction of the milk from different quarters of the udder varied greatly, but in most cases the variations were not large. In general a decrease of acidity is associated with a marked tendency towards a decrease in specific gravity, and in percentage of fat, total solids, solids not fat, caseinogen, and lactose, but an increase in proteins other than caseinogen and in ash and chlorine. These changes are such as would be expected if blood serum or lymph were added to normal fresh milk. Abnormal conditions of the udder might cause such additions. Examination of milks of low acidity, pH above 6.80, indicates that the reaction is accompanied by the presence of large numbers of leucocytes, though the reaction in such cases may be neutralised by the presence of large numbers of acid-producing streptococci.—J. C. D.

Milk; Detection of abnormal — based on hydrogen ion concentration. J. C. Baker and L. L. Van Slyke. J. Biol. Chem., 1919, 40, 357—371.

ONE drop of a saturated solution of dibromo-o-cresol-sulphon-phthalein (bromo-cresol purple) in water is added to 3 c.c. of milk and the colour observed. Normal fresh milk gives a greyish-blue colour. The production of a darker or lighter colour serves to awaken suspicion in regard to the normal character of the milk. The colour is made lighter by acids and formaldehyde, and by heating above the usual point of pasteurisation. The colour is of deeper blue in the case of milk from diseased udders, watered milk, skimmed milk, and milk containing alkaline salts. The method has been applied to 570 samples of market milk and has given trustworthy results. Colour standards can be prepared.—J. C. D.

Milk; Determination of keeping quality of — J. C. Baker and L. L. Van Slyke. J. Biol. Chem., 1919, 40, 373—382.

BROMO-CRESOL purple (see preceding abstract) can be used to measure approximately and relatively the keeping quality of milk. The test is applied as given in the preceding paper, with the modification that the pipettes and tubes employed must be sterilised before use, and that the samples under test must be incubated for a given time at 18°—20° C. The milk is examined for change of colour at 24-hour intervals. The main factor shown by this test as related to keeping quality is production of acid, but additional factors to be observed are coagulation of caseinogen, digestion of caseinogen, production of alkali and gas, and development of abnormal odour or taste. In the development of acidity four stages of progress are distinguishable through change of colour. In comparing this test with the bacterial count, it is found that in general large numbers of bacteria and increase of acidity are in fair correlation.—J. C. D.

Milk; Heat coagulation of — H. H. Sommer and E. B. Hart. J. Biol. Chem., 1919, 40, 137—151.

THE coagulation of milk by heat occurs at from 130° to 150° C., with different samples of milk. In the manufacture of condensed milk this coagulation may occur during the sterilisation of the finished product sealed in tins. Manufacturers have attempted to solve the problem by controlling the acidity of the milk, and have set an arbitrary standard, such as 0.18% acid (calculated as lactic acid), above which they reject all milk. Frequently, however, milk, immediately after it is drawn from the cow, has a higher acidity (as determined by titration) than this value. This was the case in approximately half of the samples of freshly drawn milk examined. Study of the factors which govern the heat coagulation of milk showed that in fresh milk

there is no direct relation between the acidity found by titration and coagulation. Acidity measured by titration is, however, no measure of the true reaction, which can only be estimated by a determination of the hydrogen ion concentration. Further experiments showed that the reaction of the milk, as determined by measurement of the hydrogen ion concentration, is not the determining factor in the heat coagulation. The reaction may, however, be a factor, for if the reaction is changed by addition of small amounts of acids the coagulation point is lowered. The concentration of the milk may also be a factor, but neither this nor the hydrogen ion concentration is the chief cause of the coagulation. The main factor was found to be the composition of the salts of milk. Electrolytes have a very marked effect on the stability of the colloids of the milk. Caseinogen requires a definite optimum calcium content for its maximum stability. The calcium content of caseinogen is largely governed by the amounts of magnesium, citrates, and phosphates present. In most cases coagulation can be prevented by the addition of citrates or phosphates, and it appears that the coagulation may be due either to an excess or a deficiency of calcium and magnesium.—J. C. D.

Casein; Solubility of — in dilute solutions of sodium chloride and its dependence on the hydrogen ion concentration. S. Ryd. Arkiv Kem. Min. Geol., 1917-18, 7, No. I, 1-15.

THE solubility of casein at 18°-20° C. increases from 6.4 mgrms. per c.c. in 0.0365N NaCl to a maximum of 3.46 mgrms. per c.c. in 0.1150N NaCl, and then falls to 1.32 mgrms. per c.c. in 0.2725N NaCl. The hydrogen ion concentration of all saturated solutions is the same and has the value 5.13×10^{-8} . The appearance of an opalescence in solutions of casein occurs when the hydrogen ion concentration has the above value, and this point lies very near the iso-electric point.—J. F. S.

Yeast; Extraction and concentration of vitamine of —. T. B. Osborne and A. J. Wakeman. J. Biol. Chem., 1919, 40, 383-391.

THE authors have prepared a highly active growth-promoting fraction from a dilute acetic acid extract of yeast by fractional precipitation with alcohol. No definite substances were isolated.—J. C. D.

Vitamines; Identity of water-soluble growth-promoting and anti-neuritic —. H. H. Mitchell. J. Biol. Chem., 1919, 40, 399-413.

THE author does not consider that there is sufficient experimental evidence available to justify the assumption that the two accessory factors are identical.—J. C. D.

Vitamine; Fat-soluble — in roots and observations on water-soluble vitamine in roots. H. Steenbock, E. G. Gross, and M. T. Sell. J. Biol. Chem., 1919, 40, 501-529.

THE yellow sweet potato and the carrot contain appreciable amounts of the fat-soluble accessory factor, and are much richer sources of this dietary constituent than rutabagas, dasheen, beets, parsnips, potatoes, and mangels. The carrot, rutabaga, and dasheen are richer sources of the water-soluble accessory factor than sweet potatoes, mangol, and sugar beet.—J. C. D.

Tomato seed and grape seed; Possibility of commercial utilisation of —. J. H. Shrader. J. Ind. Eng. Chem., 1919, 11, 1131-1135.

IS making tomato catsup, pulp, soup, etc., the skins, cores, and seeds are separated from the juice and pulp; the waste (skins etc.) amounts to about 5% of the fruit and contains 10% of seeds. Grape pomace is about 20% of the grapes and contains

about 25% of seeds. These two waste products are obtained in factories in many different districts, but not in sufficient quantity in any one to make utilisation profitable. By working out the cost of transport etc., the author comes to the conclusion that a fair profit could be made by bringing the seeds alone to some central point and there pressing them to obtain oil and press-cake, but that it would not be profitable to transport the whole of the wastes.—W. P. S.

Whale (blubber) oil; Use of hydrogenated — as a food. H. Thoms and F. Müller. Z. Unters. Nahr. Genussm., 1919, 38, 191-198.

FEEDING experiments on men showed that hydrogenated whale oil, m. pt. 36°-37° C., is an efficient substitute for butter.—W. P. S.

Food dehydration; Low temperature-vacuum —. K. G. Falk, E. M. Frankel, and R. H. McKee. J. Ind. Eng. Chem., 1919, 11, 1036-1040.

THE dehydration of meat at 50°-70° C. under a pressure of 2 in. of mercury results in the reduction of the water content by 65% in from 3 to 8 hrs., according to the size of the pieces. Subsequent exposure to the atmosphere for 3 days further reduces the water-content, and the meat then contains about 10% of water. Fish, vegetables, and fruits may be dried in a similar way, and all the products are of a satisfactory character.—W. P. S.

Vegetables; Carbohydrates of fresh and dehydrated —. K. G. Falk. J. Ind. Eng. Chem., 1919, 11, 1133.

DETERMINATIONS of reducing sugars, dextrans, and starch (soluble and insoluble) in fresh and dehydrated (air or vacuum) carrots, potatoes, cabbages, and turnips showed that the drying process did not cause any change in the carbohydrate distribution.—W. P. S.

Foodstuffs and feeders; Quantitative micro-analysis of —. W. Herter. Z. Unters. Nahr. Genussm., 1919, 38, 65-89.

A DESCRIPTION of methods of preparation and microscopical examination of various food products and feeding stuffs, including methods of calculating the proportions of various components from the diameters of their particles observed under the microscope.

Food; Prepared health — and process of making the same. Fruited Cereal Co., Assignees of J. P. Pursell, Quincy, Ill., U.S.A. Eng. Pat. 121,284, 3.12.18. (Appl. 19,984/18.) Int. Conv., 4.12.17.

A CEREAL is cooked in the form of whole grains, e.g., by direct action of steam under pressure; fruit—preferably consisting of a mixture of dates, figs, and raisins, which may have been previously dried and ground—is then added to the cereal. Cooking is continued for some time further, and the product is then dried and toasted and if necessary granulated.—J. H. L.

Baking compound. W. P. M. Grelek, Assignor to B. H. Grelek, Lincoln, Nebr. U.S. Pat. 1,322,561, 25.11.19. Appl., 4.12.15.

THE product consists of the dried solids of sour milk mixed with an alkaline carbonate.—J. H. L.

Dehydrating fruits, vegetables, etc.; Process of and apparatus for —. C. Shorman, Chicago, Ill. U.S. Pat. 1,321,072, 9.12.19. Appl., 4.6.13.

THE material to be treated is contained in a closed

chamber from which the air is exhausted, the air after withdrawal being compressed, freed from moisture in a condenser (preferably consisting of a coil or coils of pipe in a tank or tanks of water), and then (reheated if necessary in another coil) used again for dehydration.—B. M. V.

XIXB.—WATER PURIFICATION; SANITATION.

Boiler feed water; Lime-barium softener for treatment of —. C. A. Mehring. Chem. and Met. Eng., 1919, 21, 629—632.

THE water to be treated is admitted through a valve controlled by the amount of water drawn from the softening plant to a tank at the top of the apparatus, whence it passes through a siphon tank to the bottom of a lower, outer cone, where it is intimately mixed with slaked lime which has been mixed to a thin paste with a portion of the water under treatment. This removes temporary hardness. As the water rises in the outer cone the precipitate settles and is drawn off at the bottom. The water passes through a pipe leading from the top of the lower, outer cone to the bottom of an inner, upper cone where it is thoroughly mixed with barium carbonate, thus removing permanent hardness. The impurities settle as the water rises in the cone and are drawn off, whilst the water passes through a filter comprising a perforated plate, a brass screen, 6 inches of gravel, and 16 inches of sand, and is collected in a triangular space below the filter bottom, whence it is drawn off as required. The filter is provided with air washing and water washing devices. The operation is controlled by the analysis of drip samples taken through $\frac{3}{8}$ " pipes at various parts of the plant. Details of analyses and results and cost of treatment are given.—S. S. A.

Carbon monoxide; Rapid determination of — in air. A. B. Lamb and A. T. Larson. J. Amer. Chem. Soc., 1919, 41, 1908—1920.

Two methods for the rapid estimation of small quantities of carbon monoxide in air are described. In the first, the gas is passed over a platinum wire heated to redness and the carbon monoxide partially burnt in contact with it. The gas then passes over heated copper oxide where the carbon monoxide is completely burnt, next through a spiral tube contained in a thermostat to bring it to its original temperature, and finally over a second exactly similar platinum wire heated by the same current as the first. The two platinum wires are made arms of a Wheatstone bridge, and since the first wire will necessarily be hotter than the second they will have different resistances. The change in the resistance of the first wire gives a measure of the carbon monoxide concentration. In the second method the mixture is passed through a platinised platinum catalyst when the carbon monoxide is completely burnt. The temperature change is measured by a thermo-element and indicates the concentration of the carbon monoxide. Both methods are rapid and the latter is particularly accurate, easy to instal and operate. The catalyst, with reasonable precautions, remains active for many weeks.—J. F. S.

Mustard gas; Effect of moisture content on the permeability of fabrics to —. G. H. Clowes, G. St. J. Perrott, B. Gordon, and E. L. Greensfelder. J. Ind. Eng. Chem., 1919, 11, 1016—1019.

THE addition of 4—5% of water to heavy duck and a gelatin-impregnated fabric facilitated the passage of mustard gas through the fabrics; with large amounts of water the passage of the gas was partially inhibited. A corresponding but smaller in-

crease in permeability occurred when oiled cloth was treated with water in quantity up to 4%. It appears that at the point of maximum penetration a film of water covering the fabric interferes with surface adsorption of the mustard gas and possibly aids the passage of the gas along the surfaces by capillarity. With more water, and as the interstices of the fabric are filled gradually with water, the passage of the gas would be at first impeded and ultimately almost inhibited, since the rate of passage by solution in water and diffusion would necessarily be slow and associated with considerable hydrolysis of the gas.—W. P. S.

Ammonia respirators. Perrott and others. See VII.

PATENTS.

Softening, treating, and filtering water for steam boilers and other industrial purposes; Automatic method of —, and apparatus therefor. E. Wade-Wilton and W. Hepworth, Bramley, and C. H. Fuessly, Eccles. Eng. Pat. 136,225, 6.12.18. (Appl. 20,216/18.)

WATER to be treated enters a tank through a control valve, and is raised in temperature by the introduction of live steam. A predetermined quantity of reagent is then automatically added and mixed, and the water is discharged from the tank through a protected pipe which prevents the discharge of any scum. From the tank the water passes to a filter, through which it travels in an upward direction, and leaves by a pipe at the top. This pipe is bent downwards and then upwards, and opens in an enclosed space, from which the air escapes by a vent valve, and the water flows away through a pipe in the bottom of the space to the boiler or to a collecting tank.—J. H. J.

Water; Purification of — [with chlorine]. F. P. Candy, London. Eng. Pat. 136,266. (Appls. 20,671, 12.12.18 and 3955, 18.2.19.)

AN apparatus is described specially suitable for the addition of chlorine gas from a cylinder of the liquid substance to water flowing in a closed conduit under pressure. The gas is admitted to a pressure-regulating chamber partly filled with water by a connection to the water conduit. A float or diaphragm in the pressure regulator operates a valve which controls the admission of the gas, so that the pressure of the gas in the regulator is reduced to that of the water. The regulator is placed at a lower level than the conduit, so that the water in the regulator is at a slightly higher pressure than that in the conduit, which enables the gas to be passed from the regulator into the conduit. The pressure regulator may be placed at a higher level than the conduit if desired, in which case the water in the regulator is supplied under the action of an air pressure controlled by the water pressure in the conduit. If the water to be treated is flowing through a suction pipe, the water for the pressure regulator is supplied from a tank at a suitable height above the regulator. In order to prevent the corrosive action of moist chlorine, the regulator may be filled with carbon tetrachloride, and a trap is inserted between the regulator and the water conduit to prevent carbon tetrachloride from entering the latter. The same object may be effected by a layer of paraffin oil on the surface of the water in the regulator.—J. H. J.

Water purification. W. O. Snelling, Pittsburgh, Pa. U.S. Pat. 1,325,213, 16.12.19. Appl., 31.7.15.

PORTLAND cement is hydrated with an excess of a hydrating agent containing a salt of one of the alkali metals which is capable of removing calcium from the cement. The product is a water-softening agent.—J. H. J.

Refuse; Destruction of house and other —, and the recovery therefrom of useful materials. E. Box, Caulfield, Victoria. Eng. Pat. 136,243, 9.12.18. (Appl. 20,427/18.)

REFUSE is treated in a closed and heated retort with air or superheated steam delivered below the charge. The gases given off are collected from the top of the retort, cooled to deposit tar, and passed through a condenser into a scrubber divided into compartments by baffles partly submerged in a liquid. In each compartment a scrubbing-box is mounted crankwise on a common spindle passing through the scrubber. The boxes are wetted as they rotate by liquid obtained from the condenser and supplied from a tank above the scrubber. The gases from the scrubber pass to a blower which also takes in air through a valved inlet. The blower is supplied also with powdered carbonaceous material (obtained from the refuse after burning in the retort), which is discharged with the air and gases through the nozzle of the blower into the furnace of the retort.—J. H. J.

Waste material; Process and apparatus for reduction of organic —. C. G. Darrach, Assignor to G. Darrach, Philadelphia, Pa. U.S. Pat. 1,325,352, 16.12.19. Appl. 29.7.15.

AN apparatus is described consisting of a digester connected at the bottom to a clarifying chamber containing granular material supported between two bodies of liquid. Organic material is treated in the digester, and the liquid from the digester is passed into the clarifier, where a flock-forming reagent is added to it.—J. H. J.

Insecticide. H. A. Richter, Long Island City, N.Y. U.S. Pat. 1,321,818, 16.12.19. Appl. 18.8.17.

ABOUT 9—15 parts of arsenious oxide and 6—10 parts of caustic alkali are ground together in a dry state and mixed with 70% of an inert dry powder containing slaked lime. The product is free from lumps, and is capable of being applied as a dusting powder.—J. H. J.

Purifying gas. Eng. Pat. 135,931. See 11A.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; Use of silicotungstic acid for the determination of —. E. Taigner. Z. anal. Chem., 1919, 58, 346—352.

ATROPINE, strychnine, and cocaine are precipitated completely from their respective hydrochloric acid solutions by 10% silicotungstic acid solution; after the addition of sodium chloride, the precipitate is collected on a filter, washed with 1% hydrochloric acid, dried at 40° C., and weighed. The precipitated compounds have the general composition: $12\text{WO}_3 \cdot \text{SiO}_2 \cdot 2\text{H}_2\text{O} \cdot \text{alkaloid}$, consequently the atropine compound contains 28.61, the strychnine compound 31.69, and the cocaine compound 29.10% of alkaloid.—W. P. S.

Ethylmorphine sulphate. J. L. Thomson. Pharm. J., 1920, 104, 7.

ETHYLMORPHINE sulphate has the formula $(\text{C}_{17}\text{H}_{19}\text{O}_2 \cdot \text{N} \cdot \text{O} \cdot \text{C}_2\text{H}_5)_2 \cdot \text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$; at 15.5° C. 1 part of the salt is soluble in 9.5 parts of water or 111 parts of 90% alcohol.—W. P. S.

Drugs and poisons; Physical theory of the action of —. I. Traube. Biochem. Zeits., 1919, 98, 177—197.

A THEORETICAL paper. The pharmacological action

of drugs and toxins is attributed mainly to their physical properties. It is urged that more attention ought to be given to the physical side of these principles in the study of chemotherapy.—S. S. Z.

Homologues of hydroquinine and their toxins; Surface action of the —. I. Traube. Biochem. Zeits., 1919, 98, 197—205.

WITH the hydrocupreins and their homologues there is a parallelism between their disinfecting power against many bacilli and cocci, mostly gram positive organisms, and their surface action. An analogy also exists between the susceptibility of bacteria towards basic stains and their power of adsorption of hydrocupreins and their toxins.

—S. S. Z.

Kephalin; Glycerophosphoric acid in —. P. A. Levene and I. P. Roff. J. Biol. Chem., 1919, 40, 1—16.

THE presence of glycerophosphoric acid in kephalin has been established by the isolation and identification of that component. It is apparently identical with the acid found in lecithin. (See further, J. Chem. Soc., 1920, i., 137.)—J. C. D.

Thyroxin; Chemical identification of —. E. C. Kendall and A. E. Osterberg. J. Biol. Chem., 1919, 40, 265—331.

EVIDENCE as to the supposed structure of thyroxin, the physiologically active component of the thyroid gland, is reported. The compound may occur in several isomeric forms, and appears to be a 4,5,6-tri-hydro-4,5,6-tri-iodo-2-oxy- β -indolepropionic acid. (See further, J. Chem. Soc., 1920, i., 180.)—J. C. D.

Yeast nucleic acid; Structure of —. H. Ammonia hydrolysis. P. A. Levene. J. Biol. Chem., 1919, 40, 415—421.

THE author reviews the recent theories of Jones (this J., 1916, 707; 1917, 402) and Thannhauser (compare this J., 1916, 63) regarding the structure of nucleic acid, and points out their weak points. He advances a formula for yeast nucleic acid which satisfies the known facts. (See further, J. Chem. Soc., 1920, i., 193.)—J. C. D.

Pepsin; Quantitative estimation of —. Effect of hydrogen ion concentration. J. H. Northrop. J. Gen. Physiol., 1919, 2, 113—122.

THE change of electrical conductivity during peptic digestion may be employed as a measure of the amount of pepsin present. The combination of pepsin with the substrate and the influence of the reaction of the medium on this combination, and hence on the rate of digestion, is discussed. (See further, J. Chem. Soc., Feb., 1920.)—J. C. D.

Catalysis; Thermal problem in organic contact —. W. J. Huff. Trans. Amer. Electrochem. Soc., 1920, 175—191. [Advance proof.]

A GENERAL review of the heat problems met with in organic catalytic reactions with a more detailed description of specific typical examples. As typical endothermic reactions the cracking of petroleum by the Rittman process, and the dehydration of ethyl alcohol over aluminium oxide, are cited. In these cases momentary local superheating entails locally increased reaction velocity and consequently locally increased absorption of heat, so that the reaction itself serves, figuratively speaking, as a thermal balance wheel. When the product, therefore, is stable enough to use a long reaction tube, as is the case with the catalysis of alcohol to ethylene, an endothermic catalysis presents no great difficulties. In the cracking of petroleum, however, the desired products are themselves liable to further decomposition, and the catalysis must be conducted within very narrow limits of temperature, e.g., 550°—

580° C. for Pennsylvania oil. The problems offered by exothermic reactions are more difficult of solution. As examples of such are cited the partial combustion catalysis of naphthalene to phthalic acid (see Gibbs and Conover, Eng. Pat. 119,518; this J., 1918, 684A) and of benzene to maleic anhydride (U.S. Pat. 1,318,632; this J., 1920, 44A), and chlorination catalyses such as the preparation of carbon tetrachloride from methane and chlorine with the aid of a treated charcoal catalyst. For disposing of the surplus heat various methods are adopted. A well-known expedient consists in increasing the heat capacity of the incoming vapours by dilution with an inert material, or an excess of one ingredient, the method adopted, for example, in the catalytic reduction of acetaldehyde to ethyl alcohol (see Eng. Pat. 120,163; this J., 1919, 28A). The latent heat of vaporisation of an atomised liquid may also be utilised for absorbing surplus heat. For large scale production the author favours the principle of alternate coolings and short catalyst contacts, although the practical application to reactions catalysed only by non-metallic materials present many difficulties.—G. F. M.

Saccharin and benzoic acid; Separation of — E. Schowalter. Z. Unters. Nahr. Genussm., 1919, 38, 185—194.

SACCHARIN and benzoic acid are extracted together from foods, etc., by most of the methods employed for the determination of benzoic acid, but the two substances may be separated from one another by means of carbon tetrachloride, in which saccharin is practically insoluble. The ethereal solution obtained as in Von der Heide's method for the determination of benzoic acid (this J., 1910, 367) is evaporated at a low temperature, the residue dried in a vacuum desiccator to remove the last traces of acetic acid, and then treated with carbon tetrachloride. The benzoic acid dissolves and may be titrated. The insoluble residue of saccharin may be identified as such by the usual reactions. Saccharin cannot be separated from benzoic acid by sublimation, since both begin to sublime at about 120° C. Attention is directed to the fact that saccharin, its anhydride and sodium salt, benzoic acid and soluble benzoates are all absorbed to a considerable extent by animal charcoal from their aqueous solutions.—W. P. S.

Acetylsalicylic acid. J. H. Ramsay. Pharm. J., 1920, 101, 7—8.

OF 11 samples of acetylsalicylic acid examined by the author only 3 were free from salicylic acid; the quantity of this acid present in the other 8 samples varied from 3 to 15 parts per million. Ten out of 12 samples of acetylsalicylic acid (aspirin) tablets contained free salicylic acid, the amounts varying from 7 to 50 parts per million.—W. P. S.

Carbamide [urea]; Decomposition of — in the presence of nitric acid. T. W. Price. Chem. Soc. Trans., 1919, 115, 1354—1360.

THE reaction between urea and nitric acid is unimolecular, and as the products consist entirely of carbon dioxide and ammonium nitrate it is analogous to the decomposition of urea by hydrochloric or sulphuric acids and proceeds according to the equations:

As the velocity diminishes with the concentration of nitric acid it appears that only free urea, and not its nitrate, takes part in the reaction (1) above. According to the dissociation theory of the decomposition of urea, whereby ammonia and cyanic acid are supposed to be the primary decomposition products, the addition of a salt containing an ammonium ion should have a retarding influence on

the decomposition, but the reverse was found to be the case, and hence it appears that this theory is not applicable. The decomposition velocity is small below 80° C., and at 30°—40° C. is negligible, and hence the use of urea to remove nitrous acid from nitric acid will not be accompanied by a loss of nitric acid at low temperatures.—G. F. M.

Fatty acids; Volatility with steam of lower — in dilute aqueous solution. E. J. Witzemann. J. Amer. Chem. Soc., 1919, 41, 1946—1951.

THE volatility of the lower fatty acids (formic to butyric) in steam increases with increasing molecular weight. The addition of neutral chlorides to the solution increases the volatility. The amount of increase runs parallel with the electro-affinity of the metallic ion of the salt. The following order is given for metallic chlorides: potassium, sodium, strontium, barium, calcium, magnesium, and aluminium. The chlorides of iron, manganese, and copper are irregular in their action. (See also J. Chem. Soc., 1920, i., 138.)—J. F. S.

Methyl ethyl ketone; Production of — from *n*-butyl alcohol. A. T. King. Chem. Soc. Trans., 1919, 115, 1404—1410.

METHYL ethyl ketone is produced from *n*-butyl alcohol by dehydration to β -butylene, re-hydration of the latter to *sec*-butyl alcohol, and dehydrogenation of the alcohol to the ketone, according to the scheme:

The dehydration of butyl alcohol is effected by passing the vapour over glacial phosphoric acid on pumice contained in a copper tube at a temperature of 280°—400° C. The β -butylene, produced without any appreciable side reactions, is condensed, the liquid shaken under its own pressure with 75% sulphuric acid, and, when absorption is complete, the mixture diluted with an equal volume of water, and distilled. A yield of about 90% of the theoretical quantity of *sec*-butyl alcohol is obtained from the distillate after salting out and drying, and it is then dehydrogenised over a catalyst of reduced copper at 290° C. by the method of Sabatier and Senderens. The yield of the purified ketone amounts to about 70% of the theoretical calculated from the crude butylene employed.—G. F. M.

Chemotherapeutic studies on organic compounds containing mercury and arsenic. G. W. Raiziss, J. A. Kolmer, and J. L. Gavron. J. Biol. Chem., 1919, 40, 533—552.

A NUMBER of new compounds containing both mercury and arsenic in organic combination have been prepared. These compounds are of the type of substituted phenylarsinic acid mercuric acetates. They were not found to possess germicidal properties superior to those of ordinary organic mercury compounds. (See further, J. Chem. Soc., 1920, i., 196.)—J. C. D.

Arsenious acid; Influence of — on growing tissues. R. Cobet. Biochem. Zeits., 1919, 98, 294—314.

IN plants, no improvement in the growth was observed by the application of arsenious acid. Concentrations as low as 1/200,000 were found to be very toxic. Frog spawn and tadpoles were not so susceptible to the toxic effect of arsenious acid, but neither improvement nor retardation in growth of these organisms could be traced to the influence of the arsenic compound.—S. PATENTS.

Alcohol; Manufacture of —. Elektrizitätswerk Lonza, Gampel, Switzerland. Eng. Pat. 134,521, 8.8.19. (Appl. 19,573/19.) Int. Conv., 27.10.18.

Is the catalytic reduction of acetaldehyde to ethyl alcohol by means of an excess of hydrogen, which, after the separation of the alcohol formed, is returned to the operation by a circulating device (Eng. Pat. 120,163; this J., 1919, 28a), the production of ether as a by-product and the gradual poisoning of the catalyst by the decomposition products of acetaldehyde, are avoided by circulating with the hydrogen an amount of oxygen not exceeding 0.3. The temperature of the reaction chamber is maintained between 90° and 170° C. by cooling, or preferably by using the hydrogen in such excess that it absorbs and removes the superfluous heat of the reaction. Whereas without the use of oxygen the yield of alcohol fell after 30 hours nearly to zero, an average yield of 95% of the alcohol theoretically possible was obtained in a run extending over 211 hours in which 0.15% of oxygen was used, whilst a content of 3.5% of ether in the condensed products in the former case was reduced to 0.5% in the latter. —G. F. M.

De-toxicated vaccine; Preparation of —. D. Thomson, London. Eng. Pat. 136,036, 11.2.19. (Appl. 3695/19.)

In the preparation of vaccines from bacteria the removal of undesirable toxins is effected by dissolving the centrifuged bacteria in N/10 sodium hydroxide at blood heat and re-precipitating the bacterial substance by the addition of N/5 hydrochloric acid containing 2.5% of sodium chloride. Precipitation is promoted by centrifuging, and as it occurs more readily in concentrated solutions it is important to dissolve a maximum amount of germs in a minimum amount of alkali, e.g., in an equal bulk of N/10 solution. The supernatant fluid contains a proportion of the toxin present, but by resolution and re-precipitation repeated several times until the supernatant liquid ceases to give a precipitate with picric acid, the final germ precipitate is rendered free from toxic substances. As an alternative to repeated solution and re-precipitation the toxin may be removed by washing the first precipitate obtained with a weak acid solution such as 0.5% solution of sodium dihydrogen phosphate. De-toxication is usually complete after 4 or 5 washings. In either case the de-toxicated precipitate is collected and mixed with a solution containing 0.5% each of sodium dihydrogen phosphate and phenol and is standardised to a strength of ten thousand millions of germs per c.c.—G. F. M.

Acetylsalicylic acid; Process for preparing double compounds of caffeine with alkali salts of —. H. Sefton-Jones, London. From Chem. Fabr. J. A. Wülfing, Berlin. Eng. Pat. 136,187, 8.1.18. (Appl. 484/18.)

ACETYSALICYLIC acid (2 mols.), an alkali carbonate (1 mol.), and caffeine (1 mol.) are homogeneously mixed and the mixture is moistened with an alcohol, ester, ketone, or chlorinated hydrocarbon of the aliphatic series to the consistency of a thick paste, which is kneaded until a sample dissolves in water to a clear solution without the liberation of carbon dioxide. The solvent is then removed by evaporation at a low temperature, and the product, con-

sisting of the acetylsalicylate of caffeine and the alkali metal is dried in a vacuum. Alternatively the acetylsalicylate of an alkali metal, such as for example lithium acetylsalicylate, may be brought into reaction with caffeine in the above mentioned proportions in a similar way.—G. F. M.

Camphor; Method of changing isoborneol into —. R. L. Andraeu, Assignor to E. I. du Pont de Nemours & Co., Wilmington, Del. U.S. Pat. 1,324,140, 9.12.19. Appl., 25.5.18.

ISOBORNEOL is oxidised to camphor with moderately concentrated nitric acid by applying momentarily, and then discontinuing the application of, an electric current.—G. F. M.

Photochemical process. W. O. Snelling, Alentown, Pa. U.S. Pat. 1,325,211, 16.12.19. Appl., 6.2.17.

A HALOGENATED carbon compound is exposed to actinic rays in the presence of a substance capable of removing the halogen.—J. H. J.

Desoxycholic acid; Manufacture of products of addition of —. H. Wieland, Munich. Eng. Pat. 105,769, 20.1.17. (Appl. 5589/17.) Int. Conv., 10.2.16.

SEE Eng. Pat. 123,685 of 1918; this J., 1919, 268 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Process plate; Emulsion for [photographic] —. R. E. Slade and G. I. Higson. Phot. J., 1919, 59, 260–265.

THE characteristic curve of a photographic plate as determined by Hurter and Driffield's method has been found to depend on the relation of the different sizes of silver halide grains present and their quantities, the thickness and opacity of the film, and the time and method of development, the first of these factors being the most important. Regarding the curve of an emulsion as the sum of the curves due to the various groups of particles of the same size, it follows that, in general, the more uniform the grains of an emulsion the steeper its curve. The actual size of the grains is less important than the degree of uniformity. A plate for process work requires to have a steep curve, and therefore to have uniformity in size of grain. Photomicrographs of a number of commercial process plates, of which several are reproduced, support this view.—B. V. S.

[Photographic] *toning with nickel and cobalt.* J. Dubreton. Bull. Soc. Franç. Phot., 1916, 6, 304.

SOLUTIONS of nickel and cobalt ferrieyanides are both suitable for toning bromide prints. Considerable latitude in the composition of the baths is permissible, the solution recommended for nickel being a mixture of equal parts of solutions containing respectively 1% of potassium ferrieyanide and 2–5% of potassium citrate in water, and 1% of nickel chloride and 2–5% of potassium citrate. The tones obtained vary from a deep, warm brown

to a red similar to that obtained with a copper ferricyanide solution; the intermediate tones, however, are pleasanter than those given by copper, and there is less tinting of the whites if toning is carried to finality. For cobalt toning, the second solution contains 2% of cobalt nitrate or chloride with 6% to 10% of potassium citrate; a violet-rose tint is given, very effective in portraits. Hard prints are preferable, and the strength of the bath in cobalt must be maintained to avoid reduction of the print.—B. V. S.

[Photographic] sulphur toning. R. Namias. 11 Progressio Photographico, July, 1914. Bull. Soc. Franç. Phot., 1919, 6, 305. Selenium toning process of Namias. J. Dubreton. Bull. Soc. Franç. Phot., 1919, 6, 306.

CRYSTALLISED sodium sulphide (60 grms.) and selenium powder (3 grms.), in the commercial form of small brownish-black sticks, are heated together in a porcelain crucible, with thorough stirring. After cooling, the mass is treated with water (1 litre), a deep red transparent solution being obtained which keeps well in full stoppered bottles. This bath gives with bleached bromide prints a fine purple-brown tone similar to that of a gold-toned print-out paper, with no tendency to the disagreeable yellowish appearance often obtained with the usual sulphide toning methods. Pure whites are obtained unless too many prints are treated in one bath.—B. V. S.

PATENTS.

Colour photography. C. Raleigh, Jersey City, N.J., and W. V. D. Kelley, Brooklyn, N.Y., Assignors to Prizma Inc. U.S. Pat. 1,325,204, 16.12.19. Appl., 20.12.16.

In obtaining a colour record, the exposure is made through a moving graded colour screen so that one end of the exposure is made to practically white light, and the other end to the full colour.

—B. V. S.

Coloured cinematograph films; Process of producing —, and apparatus therefor. L. F. Douglass, San Rafael, Cal. U.S. Pat. 1,325,280, 16.12.19. Appl., 13.8.18.

In two-colour cinematography, with alternating red and green taking screens, a portion of the green screen exposure is made through a blue screen, the proportion of blue screen exposure being increased with increase of the distance between the lens and the object.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Trinitrotoluene; Hygroscopicity of —. W. J. Huff. Chem. and Met. Eng., 1919, 21, 570—571.

THE allegation that trinitrotoluene is hygroscopic is denied. Although no measurements of the vapour pressure of its saturated solution are available, calculation from the temperature-solubility curve would indicate it to be 99.997% of that of pure water at 25° C., and this points to trinitrotoluene being practically non-hygroscopic. Laboratory tests by Taylor and Cope's method (this J., 1916, 944) are not suitable for determinations of hygroscopicities below that of potassium perchlorate, but they confirmed, nevertheless, that trinitrotoluene is not hygroscopic and that apparent gain in weight was due to deposition of moisture by adsorption and condensation attending minute temperature fluctuations.—W. J. W.

Nitrotoluenes; Studies on the —. I. Binary systems of a nitrotoluene and symmetrical trinitrotoluenes. J. M. Bell and J. P. Sawyer. J. Ind. Eng. Chem., 1919, 11, 1025—1028.

The freezing points of binary systems in which one

component was 2,4,6-trinitroxylylene and the other a nitrotoluene have been determined by the cooling curve method. Binary mixtures of trinitro-m-xylene (m.pt. 182° C.) with 1,2,4,6-trinitrotoluene (m.pt. 80.5° C.) showed an eutectic point 74.8° C., corresponding (by interpolation) to 8% of the former. The mixtures of trinitro-m-xylene and 1,2,4-dinitrotoluene (m.pt. 69.4° C.) had eutectic point 67.7° C., corresponding to 6% of the former, whilst the eutectic point (50.5° C.) of the mixtures of trinitro-m-xylene and p-mononitrotoluene (m.pt. 51.2° C.) corresponded to 2% of the former. The binary eutectic temperature for mono- and dinitrotoluenes (26.4° C.) was lowered to 25.7° C. by the addition of successive small amounts of trinitro-m-xylene, and analogous reductions of the eutectic points were produced by adding trinitro-m-xylene to mixtures of the other two nitrotoluenes. The formula expressing the relationship between the heat of fusion, m.pt., and composition of ideal solutions is applicable to binary mixtures of trinitro-m-xylene especially when mononitrotoluene is the second constituent.—C. A. M.

Nitrotoluenes; Studies on the — II. Refractive indices of mixtures of p-nitrotoluene, 1,2,4-dinitrotoluene, and 1,2,4,6-trinitrotoluene. J. M. Bell and E. O. Cummings. J. Ind. Eng. Chem., 1919, 11, 1028—1029.

THE refractive indices of mixtures of p-nitrotoluene, 1,2,4-dinitrotoluene, and 1,2,4,6-trinitrotoluene were determined at 38°—39° C., the eutectic temperatures of the mixtures being about 17° C. The results corresponding to the percentage composition by weight of the three components are given in tabular form, and lines of equal refractive index are shown in the conventional triangular diagram. In all but a few instances the observed results agreed with those calculated by means of the formula:

$$n = 1.542m + 1.572d + 1.580t,$$

where m , d , and t are the fractions by weight of mono-, di-, and trinitrotoluene in the mixture. (See also this J., 1920, 84A.)—C. A. M.

Black powder; Hygroscopic properties of —. G. B. Taylor. J. Ind. Eng. Chem., 1919, 11, 1032—1031.

THE relative rates of the absorption of moisture by three samples of ordinary black gunpowder were determined by the methods used in a previous investigation of detonators (this J., 1916, 944). The presence of potassium perchlorate (up to 5%) in mixtures with potassium nitrate has only a slight effect upon the rate of moisture absorption.

PATENTS.

Mixing materials [nitrocellulose] with fluids; Apparatus for —. E. G. Loomis, Newark, N.J., Assignor to The Arlington Co., Arlington, N.J. U.S. Pat. 1,324,774, 9.12.19. Appl., 12.12.16.

AN apparatus for mixing nitrocellulose with water by imparting motion to it whilst it is suspended in the water, and for removing the mixture through a tangential conduit.—W. J. W.

Chlorate explosives. F. Müller, Frankfurt. Ger. Pat. 307,039, 9.1.18.

BENZOATES may be used as ingredients of chlorate explosives. A typical composition consists of potassium chlorate, 3 parts; charcoal, 1 part; and sodium

benzoate, 14 parts. Such explosives are insensitive to pressure and shock, and detonate at a low temperature, approximately 150°C .—W. J. W.

Incendiary bombs and projectiles; Composition for —. Deutsche Gold- und Silberscheideanstalt vorm. Roessler, Frankfurt. Ger. Pat. 298,957, 9.5.15.

THE filling material consists of an alkali metal, mixed with a substance which readily evolves oxygen, such as sodium peroxide, sodium nitrate, etc. The latter is ignited by easily inflammable mixtures such as aluminium and iron oxide or powdered alkali metal and peroxide, and ignition of these is effected by the usual fuses or igniters or by the action of water or acids. The oxygen-evolving composition and the inflammable mixture are placed in a recess, formed in the alkali metal.

—W. J. W.

Nitrocellulose. Ger. Pats. 314,317–8. See XIII.

XXIII.—ANALYSIS.

Potentiometers for thermo-element work. W. P. White. Bull. No. 153, Amer. Inst. Min. and Met. Eng., Sept., 1919, 1763–1772.

DIRECT deflection methods of measuring temperatures by means of thermo-couples are characterised by lack of relative precision and necessitate the absolute constancy of all resistances. The limit of accuracy of such methods, variously estimated as between 1 part in 500 and 1 part in 2000, is far below that of a simple potentiometer method. This latter method is more costly as well as more complex and necessitates the use of a standard cell and attention to the working cell. Various modifications whereby these and other objections to the potentiometric method are eliminated, at least in part, are detailed. These include the pyro-volter and the Harrison and Foote instrument. In the latter the circuit resistance is adjusted to compensate for any changes or differences in the thermo-element, and the thermo-couple itself is used as a source of temporarily constant current. No battery is required. Both instruments are dependent on the calibration of an ammeter. Higher precision is as yet attainable only by the use of a standard cell. The portable potentiometer of the Leeds and Northrup Co. permits an accuracy of 0.25° with ordinary base-metal thermo-couples. The Diesselhorst-Wolff and the White designs of potentiometer (J. Amer. Chem. Soc., 1914, 36, 1859, 2011) enable readings to be made to within 0.1 microvolt. The latter form is very little affected by corrosive gases. Both are deflection potentiometers enabling part of the readings to be taken direct from the galvanometer deflections, with a gain of speed. Speed is further enhanced by using the instruments as double potentiometers. The precision possible renders these instruments suitable for use in fundamental standardisation work, and in calorimetry.—J. S. G. T.

Thermal expansion; Stretched wire apparatus for measuring —. A. W. Gray. Chem. and Met. Eng., 1919, 21, 667–671.

THE difficulties in measuring small changes in length accurately and without the errors incidental to changes in the apparatus are overcome by this device. Two wires in contact with the ends of the bar under examination are kept stretched by vanes immersed in oil, which by its viscosity prevents swinging of the wires; or, where the bar itself is immersed in a bath, the wires are stretched upwards to another bar, which is rigidly connected to the centre of the test bar, and kept at tension by weights. The ends of the sample must be ground and transverse motion of the wires caused by ex-

pansion of the sample is observed through micrometer microscopes. The apparatus may be used with accuracy at temperatures between -150° and -350°C . A description is given of a dilatometer which embodies the above device and is suitable for industrial purposes. Notes on possible errors and their correction are supplied. The apparatus may also be utilised for measuring magnetostriction in nickel steels and deformation of materials during testing.—W. J. W.

Thermal analysis; Simplification of the inverse-rate method of —. P. D. Merica. U. S. Bureau Standards Sci. Paper, No. 336, 1919.

THE recording of time cooling curves is simplified by the use of two stop watches, which are so arranged in a frame that both stems may be pressed together each time the potentiometer connected to the thermo-couple records a definite temperature. The single action stops one watch, thus recording the desired interval and starts the second watch, which commences recording the next interval. The method saves much time and the use of an expensive automatic recording chronograph.—J. F. S.

Melting point of hygroscopic substances; Apparatus for determining the —. H. J. Backer. Chem. Weekblad, 1919, 16, 1561–1565.

THE apparatus consists of a narrow, thin-walled, glass tube connected by a curved lateral branch to a wider tube. The material under examination is placed in the narrow tube, which is then drawn out and sealed. A desiccating agent, such as phosphorus pentoxide, is placed in the wide tube, which must then be drawn out to a capillary, exhausted by means of a water pump and sealed. The melting point can thus be determined while the substance is virtually contained in a vacuum desiccator.

—W. J. W.

Viscometer. G. Baume and H. Vigneron. Ann. Chim. Analyt., 1919, 1, 379–383.

AN apparatus for determining the viscosity or fluidity of liquids consists of a capillary tube widened at its lower end and provided at the top with a bulb, above which is a short length of tube. The latter passes through a cork closing a test-tube, so that the capillary portion hangs vertically with its lower end immersed to a definite length in 20 c.c. of the liquid to be examined, which has been placed previously in the test-tube. A thermometer is fitted in a tube also passing through the cork, and this tube carries a side tube, to which is attached a rubber pressure ball. The test-tube is heated in a suitable vapour jacket, and when a constant temperature is attained the rubber ball is pressed so as to force the liquid up the capillary tube, filling the bulb on the same; pressure is then released and the time noted for the level of the liquid to fall from a mark just above the bulb to one just below it.—W. P. S.

Electrometric titration; Theory of —. W. D. Treadwell. Helv. Chim. Acta, 1919, 2, 672–680.

THE end point in the titration of silver solutions may be determined by measuring the terminal voltage between a standard silver chloride cell and a silver electrode immersed in the solution being titrated. The end point is that at which the terminal voltage becomes zero. This titration may also be carried out in the presence of foreign substances by means of a method described in the paper.—J. F. S.

Electrometric titration. W. D. Treadwell and L. Weiss. Helv. Chim. Acta, 1919, 2, 680–697.

THE end point in many titrations may be determined electrometrically by measuring the terminal voltage between a metal electrode which is immersed in the solution being titrated, and is

capable of sending the same ions into solution, and a comparison electrode made of the same metal and the titration product. The two terminals are directly connected to a voltmeter, and the point of zero potential is the end point of the titration. It is essential that during the titration the liquid should be rapidly stirred, and the authors describe an apparatus in which the comparison electrode is built up in the stirrer. In the case of silver solutions the comparison electrode is Ag/AgCl (saturated solution), a silver wire is the titration electrode, and the titration is carried out with sodium chloride. With pure silver solutions the results are exceedingly good, but in the presence of foreign substances low results are obtained, which may, however, be corrected from the titration curve. Hydrogen sulphide may be titrated with silver ions, using the combination $\text{Ag}/\text{Ag}_2\text{S}$ dilute NaNO_3 as comparison electrode. Mercurous ions may be titrated with chloride ions, using as comparison electrode $\text{Pt}/\text{Ag}/\text{Hg}_2\text{Cl}_2$ dilute H_2SO_4 , and a similar silver-plated platinum wire as titration electrode. Better results are obtained if the titration is carried out with bromide ions, and the calomel in the comparison electrode replaced by mercurous bromide. Copper ions may be titrated by ammonium thiocyanate, using as comparison electrode Cu/CuCNS dilute NaHSO_3 . Zinc ions may be titrated with ferrocyanide ions, using as titration electrode a platinum gauze, and as comparison electrode $\text{Pt}/\text{Zn}/\text{Fe}(\text{CN})_2\text{HCl}$ (5 c.c. in 300 H_2O). The titration in this case is carried out in warm solution (70° C). Ferrous chloride may be titrated with potassium bichromate, using an already completed titration as comparison electrode, and platinum wires in both solutions. This titration is also carried out in warm solutions. Uranous ions may be titrated with potassium permanganate in warm solutions, using platinum wires and a uranyl solution as comparison electrode. Vanadyl solutions may be similarly titrated with permanganate, using platinum wires and a vanadate solution as comparison electrode.

—J. F. S.

Titration with surface-active substances as indicators. Acid estimations with the homologues of the fatty acid series. W. Windisch and W. Dietrich. *Biochem. Zeits.*, 1919, 97, 135—156.

ADOPTING Traube and Somogyi's method of estimating the reaction by means of the alteration in the surface tension brought about by the displacement of the acid or the base of the indicator by the acid or base of the medium (this J., 1915, 511), the authors tried the homologues of the salts of the fatty acid series up to undecylic acid as indicators. The acids with C_9 — C_{11} have been found to be as sensitive as litmus and neutral red. Free acids could be estimated in the presence of a primary phosphate by using the acids as indicators.—S. S. Z.

Gas analysis; Improved Orsat apparatus for —. G. W. Jones and F. R. Neumeister. *Chem. and Met. Eng.*, 1919, 21, 734—736.

A DESCRIPTION is given of the modified form of Orsat apparatus used by the Bureau of Mines, U.S.A., which embodies the principle of removing the hydrogen and carbon monoxide by Jager's copper oxide method, as in the modification of Burrell and Oberfell (*J. Inst. Eng. Chem.*, 1916, 8, 228). The gas burette is provided with a two-way stop-cock at the top, so as to communicate with either the Orsat pipettes containing the usual reagents for the absorption of carbon dioxide, unsaturated hydrocarbons, and oxygen, or with a compensator of the Petersen type. On raising or lowering the levelling bulb, the mercury in the compensator forms contact with a platinum wire and lights a lamp, which facilitates the reading.

Above the Orsat bulbs is an electrical heater consisting of a helical spiral of nichrome wire coated with alternate layers of a mixture of calcined magnesia and sodium silicate and asbestos cord, and covered with asbestos paper. This heater is brought to 300° C., and lowered over the copper oxide tube so that it rests upon supports. The gas is passed through the heated copper oxide tube about 3 times in each direction and then into the combustion pipette. The heater is then raised, the copper oxide tube cooled by means of a blast of compressed air, the mercury levelled, and the contraction corresponding to the hydrogen measured. The gas is then passed into the potassium hydroxide pipette several times, and again through the copper oxide tube, and the contraction corresponding to the carbon monoxide measured. A measured quantity of oxygen is introduced into the combustion pipette, the wires in which are connected with the electric current through a transformer and nichrome resistance wire and are brought to a high temperature by means of a sliding contact. The gas is slowly introduced into the pipette which is cooled externally by means of compressed air to prevent breakage during the combustion. The figures for the total contraction and amount of carbon dioxide formed give the data for the calculation of the quantities of the two predominating hydrocarbons in the gas by means of the usual formulæ. Nitrogen is obtained by difference.

—C. A. M.

Interferometer; Application of the — to gas analysis. J. D. Edwards. *Chem. and Met. Eng.*, 1919, 21, 560—565.

THE analysis of a mixture of two gases may be effected by the interferometer which measures the difference in their refractivities and the change in the refractivity of the mixture produced by a change in the proportion of one of the components. The author describes a method of calibration, and points out possible sources of error in the use of the instrument. Its application to typical mixtures is indicated and a table shows its relative sensitiveness for different gases. It may be used for the analysis of flue gases and for the determination of helium in mixtures. (See also *J. Chem. Soc.*, Feb., 1920).—W. J. W.

Potash; The De Roode method for determining —. T. E. Keitt and H. E. Shiver. *J. Ind. Eng. Chem.*, 1919, 11, 1049—1052.

FURTHER investigation (see this J., 1918, 253 A) showed that the method is trustworthy in the presence of large or small amounts of ammonium salts, organic matter, sodium nitrate, or phosphates, and that it is more accurate than the Lindo-Gladding method, the results in which vary with the kind and amounts of impurities present.

—W. P. S.

Iron; Application of rotating "reducers" in the determination of —. W. Scott. *J. Ind. Eng. Chem.*, 1919, 11, 1135—1137.

FERRIC salts in sulphuric acid solution are reduced quickly and completely by rapidly rotating cylinders of zinc or aluminium with or without the use of an electric current. The reduction appears to be somewhat more rapid with aluminium than with zinc, but the latter is more readily obtained in a sufficiently pure state. (See also this J., 1918, 544 A).—W. P. S.

Copper; Permanganate method for estimating —. L. F. Clark. *J. Ind. Eng. Chem.*, 1919, 11, 1138—1139.

THE titration of cuprous thiocyanate with permanganate solution is rendered more trustworthy when

modified as follows:—The cuprous thiocyanate is precipitated from a 2% sulphuric acid solution (other acids having been expelled by evaporation) by a solution containing 4% of sodium thiocyanate and 10% of sodium sulphite; the mixture is boiled to coagulate the precipitate, the latter is collected on a filter treated previously with starch solution and is washed with hot water containing a few drops of sulphuric acid. The precipitate and filter are then transferred to a beaker and heated with 25 c.c. of 4% sodium hydroxide solution until the paper is disintegrated and the cuprous thiocyanate decomposed; 25 c.c. of cold 15% sulphuric acid and a quantity of 1% ferric sulphate (anhydrous) solution are added and the mixture is titrated with permanganate solution. Towards the end of the titration the colour of the ferric thiocyanate fades and the mixture becomes white; 5 c.c. of concentrated hydrochloric acid is then introduced and the titration completed. Under these conditions 1 atom of copper should, theoretically, be equivalent to 7 atoms of iron, giving a ratio factor of 0.1626; as the result of actual determinations, this factor is found to be 0.1616.—W. P. S.

Tin; Indirect test for the detection of —. F. Feigl. *Chem.-Zeit.*, 1919, 43, 861.

AN ammoniacal solution of dimethylglyoxime gives a precipitate of ferric hydroxide with ferric salts, and this may mask the red precipitate given by traces of ferrous salts with the reagent. The precipitation of the iron as hydroxide may be prevented by adding an organic hydroxy compound (tartaric or citric acids or potassium sodium tartrate) which will form a complex compound with the iron. Ferrous iron is also no longer precipitated as ferrous dimethylglyoxime, but gives a carmine-red solution. This reaction may be used as a sensitive indirect test for tin. After solution of the sulphides of antimony and tin in warm strong hydrochloric acid a portion of the solution is treated with iron wire as a confirmatory test for antimony. In another portion the tin and antimony are precipitated together by means of zinc (free from lead and iron), and the tin dissolved from the metallic deposit by means of strong hydrochloric acid (the presence of a little antimony is negligible). The solution is poured into a hot dilute solution of ferric chloride, a little citric acid or potassium sodium tartrate added, and the liquid tested for ferrous iron by means of an ammoniacal alcoholic solution of dimethylglyoxime. In the presence of stannous ion the ferrous ion formed by reduction gives a red coloration, the intensity of which is proportional to the amount of stannous chloride.

—C. A. M.

Nitro-compounds; Titration and partial reduction of — with titanous chloride. C. F. van Duin. *Chem. Weekblad*, 1919, 16, 1111—1122.

THE method of estimation of nitrogen in nitro-groups by reduction with titanous chloride and subsequent titration was examined. It was found that the titre of titanous chloride solutions suffered considerable alteration after the solution had been heated and that consequently the analytical results yielded by the method were inaccurate. In presence of acids, especially hydrochloric acid, the error is small. Experiments with various classes of nitro-compounds such as nitramines (trinitrophenylmethyl nitramine, aminotrinitrophenylmethyl nitramine, trinitromethyl nitraminophenol, trinitromethyl nitramino-anisole, trinitrodimethyl dinitraminobenzene), tetranitro-compounds (tetranitrophenol, tetranitrophenylmethyl nitramine, tetranitroaniline), and hexanitro-compounds with two nuclei (hexanitrodiphenyl sulphide and sulphone) showed that the results obtained were of the same order of accuracy as is given by the Dumas nitrogen method. The method can only be considered

superior to the latter when a correction is applied for the change in titre of the titanous chloride solution, and the amount of excess of the latter solution necessary for complete reduction is known. In the reduction of nitramines side reactions may take place in which the nitramino-group is completely removed from the nucleus.—W. S. M.

Anions; Indirect electrolytic estimation of — without platinum electrodes. E. Lasala. *Anal. Fis. Quim.*, 1919, 17, 235—247. (See also this J., 1919, 391 A.)

THE anion is precipitated as insoluble silver salt. This is dissolved in a suitable solvent, e.g., ammonia solution or potassium cyanide, and the solution is electrolysed with a nickel-plated copper cathode and any iron anode. The method gave satisfactory results with carbonate, oxalate, ferro- and ferricyanide, and thiocyanate, but was found unsuitable for the estimation of orthophosphate, arsenate, and chromate. The method may be used in the separation of chloride and iodide. The precipitate of mixed silver salts is washed with ammonia solution (sp. gr. 0.92) and the chloride solution electrolysed directly. The residual silver iodide is dissolved in 20% potassium cyanide solution and electrolysed. A correction must be made for the solubility of silver iodide in ammonia.—W. S. M.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Beyer. Ring furnace and drying plants. 1453. Jan. 16.
Broadbridge. Ball mills etc. 2227. Jan. 23.
Bury, and Skinningrove Iron Co. Drying washed mineral matter. 2180. Jan. 23.
Collis Products Co. Apparatus for desiccating liquids. 1800. Jan. 20. (U.S., 13,12,15.)
Conder and Vivian. 2212, 2243, and 2245. See X.
Davis. Apparatus for drying or cooling powdered etc. substances. 2271. Jan. 24.
Dunker. Apparatus for treating air or other gas. 1469. Jan. 16.
Fesca und Sohn. Centrifuges. 978 and 979. Jan. 12. (Ger., 26,6,15 and 18,6,19.)
Frühwacht (Neumann and Neumann). Kibbling or grinding mills. 964. Jan. 12. (Ger., 9,10,16.)
Hirsch. Apparatus for generating gas by action of liquids on solid etc. reagents. 1176. Jan. 14.
Hutton. Process of drying. 940. Jan. 12.
Morshead. Cooling towers. 1606. Jan. 17.
Ten Bosch. Filtering or de-watering presses. 1678. Jan. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

- 1940 (1919). Levy. Collection and recovery of volatile solvents evaporated into the atmosphere. (137,615.) Jan. 28.
2858 (1919). Kruger. Apparatus for drying granular and other substances. (137,631.) Jan. 28.
3582 (1919). Soder. Grinding mills. (137,640.) Jan. 28.
4856 (1919). Savy. Drying apparatus. (123,984.) Jan. 28.
6175 (1919). Tullis. Process and apparatus for drying. (137,427.) Jan. 21.
8797 (1919). Wallace and Tiernan. Packing materials and processes of making the same. (131,871.) Jan. 21.
13,436 (1919). Hellner. Rotary digesters and like boilers. (137,742.) Jan. 28.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- American Coke and Chemical Co. Coke-ovens etc. 2316—2324, 2326. Jan. 24. (U.S., 3,1, 22,6, 15,9,16; 9,11,17; 11,7 and 8,9,19.)
Burton, and South Metropolitan Gas Co. Gas-producers. 1808. Jan. 20.
Byrnes. 2075. See XX.
Carmichael. 1932. See XII.
Castelli and Corthesy. Means to generate gases from coal etc. 2060. Jan. 22.
Coke Oven Construction Co., and Marr. Coke-ovens. 1512. Jan. 16.
Duckham. Manufacture of mixtures of pulverised fuel with tar etc. 2315. Jan. 24.
Fabry. Purification of coal gas. 2050. Jan. 22.
Gair, and South Metropolitan Gas Co. Incandescent gas mantles. 1392. Jan. 15.
Gledhill. Coal-carbonisation retorts. 1886. Jan. 21.
Grocott. Fuel-gas producer. 1263. Jan. 15.
Grocott. Combined gas-producer and furnace. 1407. Jan. 16.
Hudson. Method of making decolorising-carbon. 1846. Jan. 20. (U.S., 15,2,19.)

International Coal Products Corporation. Treating lignites. 1576. Jan. 17. (U.S., 30,4,19.)
Leadbeater. Manufacture of artificial fuel. 1550. Jan. 17.

Lloyd. Peat fuel. 1950. Jan. 21.
Morris. Gas-generating apparatus. 2333. Jan. 24.

COMPLETE SPECIFICATIONS ACCEPTED.

- 18,984 (1918). Rappaport. Manufacture of acetone by dry distillation of pyrolignite of lime and other acetates. (137,558.) Jan. 28.
261 (1919). Swinburne. Low temperature destructive distillation of coal. (137,572.) Jan. 28.
4010 (1919). West and Wild. Gas-producers. (137,647.) Jan. 28.
5075 (1919). McMinn. See VIII.
9893 (1919). Atkinson, and Powdered Fuel Plant Co. Combustion of powdered fuel. (137,450.) Jan. 21.
19,727 (1919). Szekey. Producing cakes of solid crude paraffin residue. (131,293.) Jan. 28.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

Oates. Manufacture of dyestuffs. 1393. Jan. 15.

COMPLETE SPECIFICATION ACCEPTED.

11,891 (1919). Imray (Soc. Chem. Ind. in Basle). Manufacture of azo dyestuffs and intermediate products. (137,733.) Jan. 28.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Bonwitt. Manufacture of dissolved or gelatinised cellulose esters. 1597. Jan. 17. (Ger., 6,6,17.)
Braun. Manufacture of cellulose. 999. Jan. 12. (Ger., 5,8,16.)
Deutsche Celluloid Fabrik. Manufacture of cellulose compounds. 2120. Jan. 22. (Ger., 9,1,18.)
Fletcher and Ward. Recovering useful products from waste celluloid. 1596. Jan. 17.
Frood. Fibrous fabrics or compositions for frictional and wearing purposes. 1426. Jan. 16.
Great Northern Paper Co. Paper-making. 1125. Jan. 13. (U.S., 25,10,18.)
Hashimoto. Obtaining new fibre from Sugamo seaweed. 1116. Jan. 13.
Jenkins. Machinery for drying, cleansing, or carbonising wool etc. 1279. Jan. 15.
Knibiehler. Treating silk. 1442. Jan. 16.
Naefe. Protecting woollen fabrics from moths. 1355. Jan. 15.
Naefe. Dressing and waterproofing textile fabrics. 1356. Jan. 15.
Stulemeyer. Treatment of viscose. 2056. Jan. 22.
Wells. Testing paper, board, textiles, etc. 1930. Jan. 21.

COMPLETE SPECIFICATION ACCEPTED.

15,007 (1919). Hollis and Woodmansey. Cleansing wool etc. in the raw state or in any stage of manufacture. (137,747.) Jan. 28.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATION.

Schwarzkopf. Bleaching, cleaning, and decolorising by bleaching-earths. 2108. Jan. 22. (Ger., 25,10,18.)

COMPLETE SPECIFICATIONS ACCEPTED.

9532 (1919). Lomax. Finishing or lustring textile fabrics. (137,710.) Jan. 28.
15,611 (1919). Textilmaschinen Fabrik A.-G. Automatic yarn bank-dyeing machine. (128,586.) Jan. 28.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- American Coke and Chemical Co. Ammonia saturators. 2325. Jan. 21. (U.S., 17,415.)
 Burt (Becker). Manufacture of oxides of phosphorus and phosphoric acid. 1709. Jan. 19.
 Chance and Hunt, Gidden, and Ragg. Manufacture of oxide and carbonate of zinc. 2007. Jan. 21.
 Commis. Production of ammonia. 2002. Jan. 21.
 Dutt and Dutt. Manufacture of sodium carbonate. 2232. Jan. 21.
 Dutt and Dutt. Manufacture of sodium hydrate, alumina, and calcium fluoride. 2233. Jan. 23.
 Dutt and Dutt. Manufacture of soluble potassium salts from feldspar. 2234. Jan. 23.
 Frischer. Process of vaporising dilute nitric acid etc. 1012. Jan. 12. (Austria, 31,816.)
 Head. Manufacture of chromic oxide and sodium sulphide from sodium chromate. 1346. Jan. 15.
 Jones and Kelly. Production of boric acid from sodium pentaborate. 2053. Jan. 22.
 Mehta. Manufacture of potassium chromate and calcium chromate from chromium ores, feldspar, and gypsum. 2025. Jan. 22.
 Mehta. Manufacture of calcium chromate from chromium ores. 2026. Jan. 22.
 Sieurin. Producing aluminium oxide from aluminium chloride. 1711 and 1712. Jan. 19.
 Soc. Ind. de Prod. Chimiques. Isolating or purifying alkali chromates. 1997. Jan. 21. (Fr., 2,817.)
 Wildman. Extraction of alumina and its salts from clay. 1231. Jan. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

- 1383 (1918). Adams and Greenwood. Manufacture of hydrogen. (137,340.) Jan. 21.
 3607 (1918). General Chemical Co. Production of ammonia from atmospheric nitrogen. (120,546.) Jan. 21.
 13,596 (1918). Curphey. Production of ammonium salts. (137,345.) Jan. 21.
 1730 (1919). Matheson. Recovering acetic acid and manufacturing acetates. (137,388.) Jan. 21.
 2042 (1919). Higgins, and United Alkali Co. Manufacture of caustic potash. (137,632.) Jan. 28.
 8552 (1919). Leach, and United Alkali Co. *See XX.*
 16,021 (1919). Norsk Hydro-Elektrisk Kvaestof-aktieselskab. *See XVI.*

VIII.—GLASS; CERAMICS.

APPLICATIONS.

- Corning Glass Works. Heat treatment of articles. 1607. Jan. 17. (U.S., 17,319.)
 Laurie, Ormandy, and Osmosis Co. Refractory articles made from china clay, and method of manufacture. 2077. Jan. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

- 4956 (1919). Mathy. Machine for re-melting glass articles. (137,660.) Jan. 28.
 5075 (1919). McMinn. Glazing-cement for use in fireclay retorts and furnaces. (137,419.) Jan. 21.
 17,560 (1919). Harrison. Abrasive material, and process of making same. (137,490.) Jan. 21.

IX.—BUILDING MATERIALS.

APPLICATIONS.

- Dutt and Dutt. Manufacture of Portland cement from feldspar residues. 2231. Jan. 23.
 Fish. Seasoning, sterilising, and drying wood. 1285. Jan. 15.
 Fish. Manufacture of wood. 1286. Jan. 15.
 Jones. Manufacture of fireproof composition for building slabs, tiles, etc. 2080. Jan. 22.

Norton Co. Manufacture of flooring compositions etc. 2294, 2295. Jan. 21. (U.S., 1 and 14,219.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Ashcroft. Electrolytic production of magnesium from anhydrous magnesium chloride. 1981. Jan. 21.
 Ballantine. Production of metallic alloys. 1137. Jan. 13.
 Bury, and Skinningrove Iron Co. 2180. *See I.*
 Coles. Coating steel and iron with brass. 1142. Jan. 13.
 Coles. Apparatus for Sherardising. 1143. Jan. 13.
 Conder and Vivian. Crushers or mills for stone or ores. 2242, 2243, 2245. Jan. 21.
 Durant and Vautin. Smelting of zinc. 2310. Jan. 24.
 Goslett, and Metals Extraction Corporation. Extraction of tin from its ores. 2226. Jan. 23.
 Honhorst. Steel alloys, and process of making same. 1829. Jan. 20. (U.S., 8,12,17.)
 International Nickel Co. Manufacture of nickel and copper. 1013. Jan. 12. (U.S., 5,2,19.)
 Macdonald. Solder for aluminium or its alloys. 2272. Jan. 24.
 Picard and Sulman. Cementation agent for copper solutions. 1924. Jan. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

- 278 (1919). Fuller, and Fuller Engineering Co. Steel-smelting furnaces. (137,574.) Jan. 28.
 781 (1919). Weyman. Cleaning blast-furnace and like gases. (137,586.) Jan. 28.
 1150 (1919). Weyman. Apparatus for cooling blast-furnace gases. (137,378.) Jan. 21.
 2566 (1919). Hills and Wheeler. Manufacture of ore briquettes. (137,626.) Jan. 28.
 2705 (1919). Wood and Wood. Cupolas. (137,399.) Jan. 21.
 4665 (1919). Oates and Green, and Ashton. Acid or like baths for treating wire. (137,414.) Jan. 21.
 7617 (1919). Rondelli. Oxidising iron or steel surfaces. (137,436.) Jan. 21.
 8023 (1919). Harris. Coating metal on metal or other conductive flat surfaces. (137,695.) Jan. 28.
 10,131 (1919). Norsk Hydro-Elektrisk Kvaestof-aktieselskab. Metallurgical reduction processes. (126,951.) Jan. 21.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Ashcroft. 1981. *See X.*
 Hepburn. Electrolysers. 1475. Jan. 16.
 King. Electric dry battery. 1089. Jan. 13.
 Oldham, and Oldham and Son. Galvanic batteries. 1025. Jan. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,567 (1918). Benjamin. Electrolytic apparatus. (137,553.) Jan. 28.
 1732 (1919). Matheson and Kaelin. Electrolytic cells. (137,609.) Jan. 28.
 3676 (1919). Van Raden and Co., and Smith. Electric storage cells. (137,641.) Jan. 28.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

- Broadbridge. Treatment of froths containing fatty matter etc. 1708. Jan. 19.
 Brooker and Royle. Manufacture of soap. 1716. Jan. 19.
 Carmichael. Purifying and clarifying oil. 1932. Jan. 21.
 Niessen. 1113. *See XIX.*

Nordiske Fabriker De-No-Fa Akt. Catalysts for hydrogenation of unsaturated organic compounds. 1126. Jan. 13. (Ger., 17.3.19.)

Nordiske Fabriker De-No-Fa Akt. Treatment of fish oils. 1129. Jan. 13. (Ger., 18.3.19.)

Schwarzkopf. 2108. See VI.

Verein. Chem. Werke. 1841, 1974—7. See XVIII.

Warburton. Treatment of oils and fats. 1016. Jan. 12.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Birkby and Birkby. Preparation of phenolic aldehyde condensation products. 1034. Jan. 13.

Chance and Hunt, and others. 2007. See VII.

Dunham. Solubilised Karaya gum composition. 1814. Jan. 20.

Hyslop. Printing, and inks etc. for use therein. 1782. Jan. 20.

Judge and Shapiro. Protecting and preserving composition or paint. 1601. Jan. 17.

Melamid. Manufacture of hard resin-like substances. 1241. Jan. 14. (Ger., 13.5.19.)

COMPLETE SPECIFICATION ACCEPTED.

14,346 (1919). Wright. Paints. (137,475.) Jan. 21.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Davidson. Treatment of rubber latex. 1690, 1691. Jan. 19.

Minton. Rubber-proofed fabrics and articles of india-rubber. 1738. Jan. 20.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

I.—GENERAL; PLANT; MACHINERY.

Steam boiler plants; Exact data on the running of —. No. III. The amount of steam used by steam jets. D. Brownlie. *Engineering*, 1920, 109, 71—74.

Of 250 boiler plants investigated 93, or 37%, were fitted with steam jet blowers. It was found that the steam used by the blowers varied from as little as 1% to 20% of the total steam produced by the plant, the average being 6.6% for hand-fired and 6.7% for mechanically-stoked boilers. The steam consumption of properly arranged blowers should not exceed 3 to 4%, faulty design or careless manipulation accounting for the balance, though in many cases it would be better to replace the steam jets by mechanical draught, which on an average takes about 2½% of the steam produced.—W. H. C.

Vacuum-evaporator plant; Air-pump capacities and incompressible-gas volumes in industrial —. E. Corner. *Engineering*, 1920, 109, 74—75.

FORMULÆ, tables, and three sets of curves are given to enable the air-pump capacity to be easily computed. The temperature prevailing in the condenser is approximately that of the outgoing or "tail" water, and this temperature governs the vacuum attainable. In general power practice the allowance for ratio of air to steam is much smaller than is practicable with industrial vacuum evaporators, which have a greater joint surface and are often dealing with liquids which give off permanent gases. The following figures for air introduced into the system, though calculated for sugar-juice, are applicable to most chemical liquids:—4 lb. of air per 1000 lb. of steam or vapour; 0.2 lb. of air per 1000 lb. of liquor treated; 0.1 lb. of air per 1000 lb. of injector water. It should be noted that the quantity of air per 1000 lb. of liquor treated varies with the number of vessels in the evaporator system.—W. H. C.

Absorption tower packing; Resistance of — to gas flow. F. C. Zeisberg. *Amer. Inst. Chem. Eng.*, Dec., 1919. *Chem. and Met. Eng.*, 1919, 21, 765—767.

THE resistance of various forms of packing was measured in an experimental tower, 30 ins. in diam., and 15 ft. high, and the superiority of artificial packings (corrugated diaphragm rings, corrugated spiral rings, Hechenbleikner blocks, chemical ware tile, and Raschig rings) over pumice, quartz, and coke was demonstrated. The general law of the flow of fluids was found to hold experimentally, and expressing the frictional resistance as the pressure necessary to produce a given flow, an equation, $p = -\frac{f h v^2}{a^2}$ is given, in which p is the pressure in inches of water, h is the height of packing in feet, v is the volume of gas passing in cub. ft. per min., a is the cross-sectional area of packing in sq. ft., and f is a coefficient differing in value according to the nature of the packing. The characteristics of various packings are shown in tabular form; the rapid increase in resistance with decreasing size of material is marked, as is also the greater resistance due to the wetting of the surface of small-sized packing material. For any given size of packing, manufactured shapes give much more surface and greater free space than do the older forms of dumped coke or quartz.—C. A. K.

Absorption of gases; New method of —. I. Moscieki. *Chim. et Ind.*, 1919, 2, 1303—1316.

AN improved type of absorption plant, especially applicable to the process of manufacture of nitric

acid from atmospheric nitrogen, has been constructed for the Soc. anon. pour l'Industrie de l'Aluminium at Chippis, Switzerland, and a similar plant for experimental purposes has been erected at Fribourg University. A description of the latter is given. It comprises two tower sections, the upper being empty and serving for the oxidation of the nitrous gases, whilst the lower is used for absorption purposes. This latter consists of two concentric tubes placed in an outer vessel, the space between them being filled with quartz fragments of 0.3—0.4 mm. in the upper part and with quartz of larger size in the lower part, which is kept below the level of the liquid. Both tubes have oblique apertures, 1 cm. diam., distributed over their surfaces. There is an outlet for the gas near the top and two outlets near the base, one for drawing off the acid and the other communicating with an air-lift. The absorbent enters a distributor through a pipe at the top, and another opening serves for admission of compressed air and liquid. The column of absorbent liquid is not high, and therefore never impedes the flow of gas. The gases are caused to enter the top segment and, after oxidation, flow into the inner tube of the lower segment, whence they pass in a horizontal direction into the intermediate space and eventually to the outlet. This horizontal flow ensures good absorption even with moderately high columns, the packing material being continuously irrigated. The conditions for the best absorption and the requisite velocity of the liquid were studied, and are summarised as regards the experimental plant.—W. J. W.

Lubricants. Frank. *See* IIA.

Handling barium products. Zimmer. *See* VII.

PATENTS.

Drying materials; Drums for —. A. Gerlach. Nordhausen, Germany. *Eng. Pat.* 133,327, 3.10.19. (Appl. 21,228/19.) *Int. Conv.*, 10.1.18.

A REVOLVING drum dryer is provided with longitudinal bars of cruciform section (see fig.) placed

in such relative positions that the material to be dried falls freely four times during each revolution, as shown by the arrows at *a*, *b*, *c*.—B. M. V.

Atomizing materials in a melted state; Process and apparatus for —. E. Odum. Paris. *Eng. Pat.* 122,403, 17.12.18. (Appl. 21,085/18.) *Int. Conv.*, 18.1.18.

THE molten material (e.g., metals, chemical products, vitreous substances) is heated by the com-

bustion under pressure, in a suitable chamber, of solid, liquid, or gaseous fuel; the products of combustion are then allowed to flow through a nozzle to the centre of which the molten material is supplied. The sudden reduction in pressure and expansion of the gases causes atomisation of the material under treatment. The combustion chamber may be divided into two communicating parts, one of which forms the combustion chamber proper and the other forms the chamber for heating the material and discharging the gases.—B. M. V.

Drying ovens; Vacuum — J. D. Taylor, Kingston Hill. Eng. Pat. 136,703, 7.2.19. (Appl. 3065/19.)

A HEATING shelf or chest for drying stoves or ovens is constructed of flattened tubular members, spaced apart horizontally and welded or otherwise jointed at each end to vertical tubular supporting members through which the heating medium is supplied and discharged. The major axes of the horizontal members are substantially parallel to the surfaces of the shelves and normal to the supporting members.—W. H. C.

Dryer. E. C. Horst, San Francisco, Cal. U.S. Pat. 1,325,848, 23.12.19. Appl., 23.4.18.

A RECTANGULAR casing is divided by parallel vertical partitions into vertical chambers. The partitions are spaced alternately from the top and bottom of the casing to provide communications between the chambers. Horizontal partitions are provided in each chamber with openings at opposite ends alternately, so as to provide a zigzag passage through the chamber. Air is passed through the chambers in series, and means are provided for reversing the direction of flow when required. Heating devices are provided in the chambers to increase the temperature of the air during its passage.—W. F. F.

Lifting and forcing apparatus for solids and semi-solids; Fluid and/or air direct pressure — S. H. and C. H. Adams, York. Eng. Pat. 136,583, 3.7.18. (Appl. 10,916/18.)

A DISPLACEMENT ejector is provided with inlet and outlet valves and with connections by means of which compressed air or other suitable fluid is delivered into the space above the material in the ejector to force the contents up the rising main and also into the body of the material itself and into the filling and discharge ducts to assist in moving the breeze, sand, or other solid and semi-solid materials which the ejector is designed to deal with. A controllable variable clockwork mechanism or a regulated electric motor allows the pressure fluid to enter the ejector during a predetermined period and then for another predetermined period the pressure fluid is shut off and the exhaust is opened.—W. H. C.

Shaft-kilns for burning or roasting non-sintering substances; Gas-fired — A. and W. W. Steiger, Zurich, Switzerland. Eng. Pat. 136,588, 11.10.18. (Appl. 16,758/18.)

IN a vertical kiln which is provided with one or more sudden increases in diameter below the combustion zone in order to loosen the material so that air for combustion may be forced through the hot burnt charge, provision is made for the continuous withdrawal of the burnt and cooled material by means of a device consisting of sloping reciprocating platforms placed under hopper-shaped guides at the bottom of the furnace.—B. M. V.

Feeding furnaces for boilers and other purposes with solid fuel; Means for — Merz and McLellan, London. A. C. Michie, Newcastle-on-Tyne, and E. G. Weeks, Monkseaton. Eng. Pat. 136,867, 20.11.18. (Appl. 19,082/18.)

THE flue gases from boilers etc., after they have

been deprived of most of their heat by economisers or the like, are passed through the solid fuel immediately before it enters the combustion chamber, the fuel being supported on a perforated grate or conveyor, separate from or combined with the combustion grate.—B. M. V.

Refrigerating systems. E. G. E. Langbert, Stockholm, Sweden. Eng. Pat. 136,602, 10.12.18. (Appl. 20,554/18.)

A VESSEL containing a suitable cold accumulator (e.g., brine) is surrounded by a suitable liquid refrigerating agent that can be vaporised by reduction of pressure (e.g., sulphur dioxide or ethyl chloride), contained in an outer vessel which may be ribbed to increase the cold-radiating surface. During working hours a vacuum is applied to the refrigerating medium, more of the liquid being admitted as required, whereby heat is absorbed from the outer atmosphere, also from the cold accumulator. During idle hours the cold accumulator absorbs heat, the refrigerating liquid serving merely to transmit heat from the outer atmosphere to the inner vessel.—B. M. V.

(A) (c) *Refrigerant and process of making the same*. (b) *Refrigerating gas and process of making the same*. A. G. Crawford, Assignor to H. W. Seaman, Chicago, Ill. U.S. Pats. (A) 1,325,665, (b) 1,325,666, and (c) 1,325,667, 23.12.19. Appl., 5.2.18, 25.2.18, and 14.10.18.

(A) BUTANE and propane are mixed in such proportions that the mixture has a boiling point below 1° C., and the mixture is then liquefied by pressure. (b) The refrigerant is a mixture of liquid sulphur dioxide and a liquefied hydrocarbon gas. (c) A gas of the ethylene series is mixed with propane in such proportions that the boiling point of the mixture is suitable for refrigeration, and the mixture is then liquefied by pressure.—W. F. F.

Evaporating or concentrating liquids; Apparatus for — E. Shaw, London. Eng. Pat. 136,651, 19.12.18. (Appl. 21,286/18.)

TO prevent the accumulation of deposit on the walls of the apparatus, which consists of an inner tube having a helix formed on its exterior and which is rotated concentrically within another tube having an external jacket, scrapers of spring steel are fitted to the edges of the helix. The liquid to be evaporated passes through the spiral passage formed by the helix.—W. H. C.

Mixing, circulating, and agitating materials in a liquid or semi-liquid state; Apparatus for — W. J. Coles, and E. Allen and Co., Ltd., Sheffield. Eng. Pat. 136,758, 19.5.19. (Appl. 12,599/19.)

AN agitator consisting of vertical frames rotates about a vertical shaft within a tank. A system of compressed air or gas supply pipes is carried by the agitator, which extends to the bottom of the tank. The system consists of horizontal pipes secured to the upper part of the agitator by which compressed air is supplied to vertical pipes, spaced at intervals, and having their open lower ends supported by slotted plates carried on the lower part of the framework.—W. H. C.

Chemical reactions; Method of and apparatus for carrying out certain — T. Hughes, London. Eng. Pat. 136,896, 21.12.18. (Appl. 21,452/18.)

IN reactions in which a solid is treated with a liquid, the solid dissolving with the evolution of gas, the reaction becomes very slow when the dissolving power of the liquid is nearly exhausted. To overcome this difficulty the solid, broken into pieces of a convenient size, is contained in a tall, narrow vessel and the liquid is admitted at the

bottom from an overhead tank. The flow of liquid is so adjusted that while the lower half of the column is bathed in liquid the upper half is filled with a froth of nearly exhausted liquid and gas. The liquid part of the froth comes into intimate contact with fresh solid material and becomes completely exhausted, and is then discharged along with some of the lighter portions of the solid through one or more overflows into a settling tank, where the gas, liquid, and mud are separated.

—W. H. C.

Pulveriser. D. McKelvey, Chicago, Ill. U.S. Pat. 1,325,676, 23.12.19. Appl. 1.4.19.

MATERIAL is fed by the conduit, 5, into the chamber, 2, in which an impact member, 7, having a dish under surface is suspended. Air under

pressure is supplied by the pipes, 30, 31, and passes into the central jet nozzle, 21, so that a jet of air mixed with the material to be pulverised is directed against the impact member, 7. Inlet openings are provided on the upper sides of the tubes, 28, so that air is drawn through them into the main air-jet and a circulation of air is maintained.—W. F. F.

Heating apparatus. W. C. Merrill, Assignor to The Merrill Process Co., Boston, Mass. U.S. Pat. 1,325,952, 23.12.19. Appl. 14.2.16.

HEATING fluid is circulated by a mechanical device operated by an electric motor, and means are provided for heating the fluid during its circulation. The fuel supply to the heater is controlled by a valve which is operated by the same electric circuit that operates the motor of the circulating device, so that the valve automatically closes when the motor is stopped and an alarm is simultaneously operated. The fuel valve is adapted to be opened automatically when the motor is re-started. (See also Eng. Pat. 128,709; this J., 1919, 612 A.)

—W. F. F.

Wrought-iron apparatus and vessels; Method for increasing the resistance of — to chemical action. F. Schüller, Frankfort. Ger. Pat. 314,824, 12.7.18.

FRAGMENTS of natural or artificial stones are worked into the iron by kneading, pressing, or rolling, and the surface is then coated with a thin, acid-resisting layer of the powdered stone. (See also Ger. Pat. 288,572; this J., 1916, 365.)

—J. S. G. T.

Delivering materials in fractions of equal weight; Apparatus for —. F. P. Martin, Paris. Eng. Pat. 136,948, 1.2.19. (Appl. 2588/19.)

Oil-fuel burners for furnaces and the like. J. Simpson and Sons (Bolts and Nuts), Ltd., Darlaston, and G. F. Everton, Wednesbury. Eng. Pat. 137,173, 7.3.19. (Appl. 5661/19.)

Separating oil or grease from water; Apparatus for —. J. H. Carruthers and Co., Ltd., J. Gourlay, C. M. Jackson, G. K. Johnstone, and J. Young, Glasgow. Eng. Pat. 137,213, 30.1.19. (Appl. 10,691/19.)

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Forms in which sulphur occurs in —. A. R. Powell and S. W. Parr. Bull. Eng. Expt. Stat. Illinois Univ. Gas J., 1920, 149, 79.

THE sulphur of coal occurs in four characteristic forms, two organic and two inorganic. The "resinic organic" type is present in the portion of the organic material soluble in phenol. The "humus organic" type of compounds are shown to be closely related to humus substances by their chemical reactions. The pyritic or marcasitic sulphur is present as FeS_2 , as indicated by the iron-sulphur ratio when the pyrites is oxidised and dissolved. The sulphate sulphur is characterised by solubility in dilute hydrochloric acid without preliminary oxidation. Free sulphur was not found in any of the coals tested, and is presumably absent except in unusual cases where it might occur in small quantities as a decomposition product of pyrites. Some of the sulphur, probably the pyritic, is gradually oxidised to the form of sulphate. The experimental data suggest that when coal is coked the sulphate sulphur is retained by the coke, but in some form other than inorganic sulphate, whilst the pyritic sulphur is partially volatilised, a portion being left in the coke, probably as sulphide. All the pyrites is decomposed. The resinic sulphur is left in the coke, but in a form different from that existing in the coal, and the humus sulphur partly volatilises, some remaining in the coke in a changed form. The analytical methods used are described in detail, and the results tabulated for different coals.—W. P.

Anthracite; Burning steam sizes of — with or without admixture of soft coal. W. P. Frey. U.S. Bureau of Mines, Tech. Paper 220, 1919. 8 pp.

A BOILER plant designed for bituminous coal and operating with natural draught is capable of using 20% of steam sizes of anthracite mixed with bituminous coal without material loss in efficiency and without change of equipment provided sufficient grate space is available. Larger proportions of anthracite may be used if a blower is added. The fineness of steam size anthracite necessitates a change of grate when the mixture contains over 40% of anthracite. Proper mixing is essential, and the coal must be fired evenly in small quantities. —W. P.

Arsa coal; Sulphur content of and yield of low-temperature tar from —. F. Fischer. Ges. Abhandl. zur Kenntnis der Kohle, 1918, 3, 98—101. Chem. Zentr., 1919, 96, IV., 977—978.

ESCHKA's method for estimating sulphur was found to be unsuitable for coal having a high sulphur content. For example, Arsa coal was found to contain 6.87% of sulphur by Eschka's method, whereas estimations by decomposition with nitric acid in a sealed tube gave 9.74—9.89%. The coal contained H₂O, 1.6%; ash, 11.4%; C, 65.94—66.14%; H, 4.83—5.02%; gave a coke residue of 55% in a crucible; benzene extract in a Soxhlet apparatus, 0.7%; benzene extract under pressure, 14.2%. In a distillation test with 10 kilos. in the rotary apparatus described previously (this J., 1919, 563A) the coal gave 1.5 kilos. of tar, 6.3 kilos. of coke, and 600—700 litres of inflammable gas. In a distillation test under ordinary conditions the coal (30 grms.) melted and gave 5.3 grms. of tar, of sp. gr. 1.02. The formation of a liquid tar and melting under heating show that Arsa coal is a true coal. The tar contains, however, in contrast to tars from most coals giving a high yield of low-temperature tar, only 10—15% of phenols.—L. A. C.

Gasification; Complete —. H. Strache. J. Gasbeuecht., 1919, 62, 709—713.

THE author discusses the advances in the supply and use of gas made by complete gasification processes during the past 25 years. The properties of water-gas—lower calorific value per cub. ft., lower air requirement, higher speed of inflammation, higher specific gravity, and non-luminous blue flame—render alterations necessary in the burners, and this has stood in the way of its more extended use. On the other hand the water-gas process possesses great advantages in its flexibility, small ground space required, and low cost of plant. Complete gasification may yield one of two kinds of gas. The first class, which includes producer gas, semi-water gas, and Mond gas, has a calorific value of 125—175 B.Th.U., and has a nitrogen content of 50% or over. The second class includes "Doppelgas" (double-gas), which has a calorific value of 360—390 B.Th.U., and contains 3—6% of nitrogen, and "Trigas" (a mixture of coal-gas, water-gas, and producer-gas), which has a lower calorific value and a higher nitrogen content than "Doppelgas." The gases obtained by complete gasification have a lower calorific value than coal gas made under pre-war conditions, but their use has many advantages (see this J., 1919, 707A). The supply of gas of high nitrogen content and low calorific value for long distance transmission is not recommended. The economy or otherwise of the recovery of by-products during complete gasification processes is being investigated by the Institut für Kohlenvergasung und Nebenproduktengewinnung in Vienna. —W. P.

Oil-gas manufacture; Experiments in connection with —. J. D. Ruys. Chem. Weekblad, 1919, 16, 746—780.

A SERIES of investigations has been made on the Rincker-Wolter process in which oil from petroleum residues is sprayed over hot coke, air and steam being admitted into the generators. Preliminary trials were carried out with Mexican Panuca crude oil, and a special method was devised to remove the sulphur from the gas produced, but other oils were found to be more suitable. The trials included investigations on the air-blast, the water-gas production, and the gasification of the oil. Extensive samples were taken of the gases at various stages, and determinations were made of the amount of water evaporated and the quantity of steam required for most effective working. An illuminating gas of 4800—5000 cals. was aimed at. The details of the trial runs and the results obtained are tabulated and plotted as curves. It was found that the yield of gas from the oil is proportional to the rapidity with which the products are removed. To ensure this, water-gas alone is insufficient and steam must be introduced. Hydrogen may be absorbed by the oil from the water-gas under certain conditions. No separation of carbon appears to take place.—W. J. W.

Producer-gas for motor vehicles. D. J. Smith. Inst. Automobile Eng., Jan. 8, 1920. Engineering, 1920, 109, 59—61, 92—95.

THE author has shown that producer-gas can be used to drive motor vehicles, and he claims the following advantages:—Home-produced fuels, some of which are even at present waste products, can be used. There is no fire risk. Producer-gas requires no labour for its production like coal-gas. No gas-bag is required. A vehicle can travel the same distance as on petrol without taking in fresh fuel. The gas is of uniform quality, so that mixture troubles are eliminated. It is the cheapest source of power for motor vehicles known at present, and with coal at 40s. per ton is equal to petrol at 2½d. per gall. when used in the same engine. A gas producer is lighter and smaller than a compressed gas installation. It requires no pressure, and is therefore free from danger. Against the above the following disadvantages must be considered. It takes from 15—20 mins. to start from cold when using a producer. The extra weight of the plant has to be taken into account. Periodical cleaning is necessary. From 3—4 mins. is required to start after a lengthy stop. There is an increase of 75% in weight of fuel, including water, to cover any given distance as compared with petrol. The following comparisons are given for a five-ton commercial lorry:—

	Steam	Petrol	Producer gas
Price of fuel	50s. per ton	3s. per gall.	55s. per ton
Cost in pence per gross ton mile	0.31	0.66	0.048
Cost in pence per net ton mile	0.75	1.20	0.091

The author's producer has been designed to do away with a thick fuel bed and to burn any volatile matter so completely that a bulky water scrubber for the gas will not be needed. The fuel bed is only about 6 in. deep and practically continuous feeding of fuel and discharge of ash are maintained by coupled feed and discharge valves. The fuel ignites at once, and the ash is not allowed to rest long enough to fuse into clinker. The only impurity in the gas is a little of the fine dust of the fuel carried over by the draught, and the gas is purified by passing it through a dry tubular scrubber heater where

the water for the producer is pre-heated. The scrubber is easily cleaned out and the producer itself is jacketed, air being passed through the jacket to the water saturator and thence to the producer. The whole apparatus weighs 2–3 cwt., and is compact enough to be carried on the dash-board of the car. The fuel (anthracite, coke, charcoal, or prepared peat) is carried in a bunker under the hood over the driver's seat, and is fed by gravity; the water is carried under the seat. Both vehicle and engine ought to be specially designed for use with producer-gas, but very fair results have been obtained with a petrol engine; the cost per gross ton mile in the same vehicle and engine was found to be 1.45d. with petrol against 0.0856d. with producer-gas. The producer-gas is better adapted to the larger and heavier commercial class of vehicles, and if generally adopted would set free petrol, benzol, etc. for the lighter pleasure cars. Experiments have shown that no danger is to be apprehended from excessive escape of carbon monoxide, even when the vehicle is standing. Anthracite in the form of "beans" which pass a $\frac{1}{4}$ - or $\frac{1}{2}$ -in. screen is the most satisfactory fuel, but coke may be used, although it contains a good deal more ash and sulphur and does not feed so easily. Charcoal is a good fuel but is bulky. Peat briquettes which have had the objectionable volatile matter driven off by heat are very satisfactory. The best results are obtained with a fuel bed of 6 in. for anthracite, 7 for coke, 4 for charcoal, and 2 or 3 in. for prepared peat.—W. H. C.

Alcohol or ether; Industrial process for the synthetic manufacture of — from the gases obtained in the distillation of coal. E. de Loisy. *Comptes rend.*, 1920, 170, 50–53.

LEBEAU and Damiens have shown that in the presence of catalysts such as vanadic, uranic, tungstic, or molybdic acids, sulphuric acid rapidly and completely absorbs ethylene (this J., 1913, 277), and it has since been shown by Damiens that the ethylene is absorbed as ethyl hydrogen sulphate. The author makes use of these two important facts in his process. The coal gas is bubbled through the acid at a concentration of 66° B., and by suitable subsequent dilution and distillation alcohol or ether may be obtained as required. The diluted acid serves for the preparation of ammonium sulphate. Since, however, twice as much acid is required for the absorption of ethylene as for the production of ammonium sulphate, a portion of the acid is concentrated by means of the waste heat from the gas coming from the coke ovens, and can thus be used either for the absorption of the ethylene or for the preliminary drying of the gases and the absorption of the traces of propylene, butylene, and acetylenic hydrocarbons present. By this method it is only necessary to replace the acid removed in the form of ammonium sulphate. (See also Bury, this J., 1920, 91 A).—W. G.

Carbon monoxide; Production of — in the flames of gases. A. Kling and D. Florentin. *Comptes rend.*, 1919, 169, 1401–1406.

A NUMBER of samples of gas, some industrial and some synthetic, containing from 0 to 60% CO, were burnt in different types of burners in a large chamber, and at the end of an hour the carbon monoxide in the air was estimated. It is shown that the production of carbon monoxide is mainly due to any sudden cooling of the flame, and for a given type of burner is practically independent of the amount originally present in the gas. The Auer burner produced comparatively large amounts of carbon monoxide, and it is shown that this is due mainly to the presence of the incandescent mantle. The hourly production of carbon monoxide with certain common types of burners is sufficiently high to warrant further efforts to improve them.

The amount of carbon monoxide coming into the air by leakage from the piping etc. of an interior supply having 14 taps, the gas containing 20% CO, is much less than the amount produced in the same time by burning the gas in a small furnace or a small Auer burner.—W. G.

Nitrogen contained in oil shales; Recovery of —. L. Simpson. *Chem. and Met. Eng.*, 1920, 22, 20–22.

THE economy of shale distillation in "single" or "dual purpose" retorts under the conditions obtaining in North America is discussed. The "dual purpose" retort, which is designed to recover a maximum of nitrogen from the shale, even at the expense of the oil content, necessitates high capital charges, and, taking into account the high local costs of sulphuric acid, labour, and plant repairs, coupled with the probable fall in value of ammonium sulphate, the view that the successful establishment of the oil shale industry depends on the continued extreme recovery of the nitrogen is not accepted. The success of the industry is held to be dependent on a single purpose retort, erected at low cost, which will yield a maximum quantity of oil, and the recovery of nitrogen is not advisable unless sulphuric acid can be obtained cheaply or unless a good local market for ammonium sulphate exists.—C. A. K.

Mineral oils; Removal of aromatic hydrocarbons from — by means of trioxymethylene-sulphuric acid. J. Tausz. *J. prakt. Chem.*, 1919, 99, 276–280.

THE efficiency of Nastjukoff's formolite process (this J., 1904, 1082) is increased by the use of trioxymethylene in place of formaldehyde solution. In the case of an oil volatile in steam, e.g., refined ligroin, 500 c.c. is added to a solution of trioxymethylene (30 grms.) in sulphuric acid (100 grms.). The mixture is kept cool and well shaken for half an hour, after which ice (500 grms.) is added, and the oil distilled with steam. Salt may be added to the mixture before the addition of ice in order to protect the hydrocarbons from the sulphuric acid. Less volatile oils are first diluted with ten volumes of previously treated petroleum spirit. It is inadvisable to prolong the treatment, because a proportion of the oil, which increases with the duration of the reaction, is always lost. Thus 1,3,4-trimethylcyclohexane soon gave a coloration with the reagent, and after two days a yellow precipitate was obtained by successively adding ice and ammonia. Aromatic hydrocarbons can be detected in gaseous mixtures by the formation of a red precipitate on shaking with 1–2 c.c. of the reagent. The reaction is also shown by diolefines, such as methyl- and dimethyl-butadienes, which contain conjugated double bonds, but in the case of aromatic hydrocarbons is limited to those which contain a hydrogen atom in the nucleus. Thus, hexamethyl- and hexaethyl-benzenes do not respond to it.—J. K.

Fuel value of volatile liquid mixtures; Determination of —. G. Barsky. *J. Ind. Eng. Chem.*, 1920, 12, 77.

THE use of gelatin capsules is recommended in the determination of the fuel value of very volatile liquids in a bomb calorimeter. They are constructed of ordinary capsules by turning in the caps so that the latter fit the menisci when the capsules are filled; all air is thus excluded. The igniting wire is wound round the capsule.—W. P. S.

Oil fractionation; Constant temperature stillhead for light —. F. M. Washburn. *J. Ind. Eng. Chem.*, 1920, 12, 73–77.

THE stillhead described is used in conjunction with

a Hempel column; it consists of a spiral made from a 12 ft. length of $\frac{3}{4}$ in. wrought iron pipe, the diameter of the spiral being about 6 in. This spiral is mounted in an oil-bath which is heated by a resistance coil immersed in the oil, and the required temperature is maintained by means of a thermostat and relay. The oil-bath is provided with a stirrer. The lower end of the spiral is connected to the side tube at the top of the Hempel column, which is 1½ in. in diameter and made of glass, whilst a side tube at the upper end of the spiral is connected to an ordinary condenser. The oil to be distilled is contained in a 1500 c.c. flask attached to the lower end of the Hempel column and heated by a Rose burner with a hemispherical top covered with asbestos-coated gauze. Thermometers are inserted in the top of the Hempel column, in the top of the spiral, and in the oil-bath respectively. The apparatus gives fractions which have a very small b. pt. range, and almost all of each of the components of a mixture (e.g., benzene, toluene, and solvent naphtha) can be distilled in a practically pure state.

—W. P. S.

Lubricants; Technical and scientific examination of —. F. Frank. Z. angew. Chem., 1919, 32, 374—379.

HILLIGER (Z. Ver. deuts. Ing., 1918, 173) estimated that approximately 0.2 gram of cylinder oil was consumed per h.p. per hour, whilst Schmidt found that although this value might be reached it was too high for the general practice of lubrication. From the experiments of Haserick and others the conclusion is drawn that not only can this value be reached, but that with good working it must be reached, since normally there is superheating up to 330° C. The use of an unsuitable oil or of an excessive quantity of a suitable oil is indicated by the appearance of the oil flecks produced on tinfoil or cartridge paper when held at a distance of about 10 cm. from the indicator tap of the cylinder, so as to receive in each test the same number of puffs of vapour. In the case of asphaltogenic oil and normal lubrication the oil fleck is diffused and shows no sign of radiating structure, whilst excessive lubrication with acid and asphaltogenic oil produces a very dark fleck with sharply defined radiations. Excessive lubrication of the cylinders of gas engines results in deposits due to incomplete combustion of the lubricant mechanically separated. Highly refined oil does not necessarily give the best results in interior lubrication. In the case of the cylinders of such engines as Diesel motors the best results were obtained with absolutely ash-free oil, which was also exceedingly pure in other respects, and had a high flash-point. It is possible also to obtain good results with such oils artificially thickened, e.g., with montan wax. The flash-point of an oil is not an absolutely decisive factor, since it may be materially lowered by the motor spirit. Hence, as a safeguard, in the case of large gas engines the flash-point should not be below 180° C., but a viscosity of 3°—4° Engler is sufficiently high. Turbine oils should be as pure as possible, so as not to emulsify readily with water, and have a high flash-point, sp. gr. as low as possible, and a viscosity of not less than 3° Engler. As a rule oils introduced into the circuit of turbines are not effectively cooled, the coolers being too small to effect complete separation of the admixed water. It is important that the oil-hole should be outside the electric field to obviate the effect of the nitric acid formed from the atmosphere upon the oil. For internal lubrication the conditions may be less stringent. Experiments in which spindle oil (viscosity 1.5° at 50° C.) was substituted for castor oil (viscosity 139° Engler) for shaft lubrication showed a reduction in the heat of friction from 34.4° C. to 6.9° C. Comparative results obtained with a good lubricating

grease and a fairly fluid mineral oil showed that the energy consumed by the latter was about 31.9% less than in the case of the grease. Details are given of an experimental plant in Düsseldorf where oils are tested under actual working conditions. Experiments on a large scale on the manufacture of lubricating oils from low-temperature tar have shown that it is not so much a question of the temperature at which the tar is separated from the coal as of removing the tar as rapidly as possible from the influence of the heat. Another important factor is that the time required for the coal to swell up should be independent of the rate at which the retort can produce gas. The oils obtained by the decomposition of tars usually show a strong tendency to form asphalt owing to the presence of unsaturated hydrocarbons, whilst owing to their high paraffin wax content they frequently solidify at a high temperature. The first drawback may be obviated by rapid distillation of the tar with superheated steam, whilst paraffin wax may be removed by the ordinary process of chilling or by Edeleann's sulphur dioxide process. Other solvents, in addition to liquid sulphur dioxide, appear to have an analogous action.—C. A. M.

Combustible matter in rocks. Fieldner and others. See VII.

PATENTS.

Artificial fuel; Manufacture of —. C. M. C. Hughes, Bognor, and T. Hill-Jones, Ltd., London. Eng. Pat. 136,584, 17.8.18. (Appl. 13,414/18.)

A METHOD is described for the manufacture of briquettes containing coke, breeze, furnace ashes, sawdust, peat, coal, or anthracite, together with pitch, filter-cake from sugar refineries, iron oxide, lime, or chalk as a binder.—W. P.

Fuel. J. V. Eyre, Chertsey, Surrey. Eng. Pat. 136,790, 12.9.19. (Appl. 22,433/19.)

THE fuel consists of coal dust 6½—10 parts, pitch 1½—3 parts, and sawdust 2—3½ parts, all measured by bulk. The powdered components are intimately mixed, and are heated to 250° F. (about 120° C.) with agitation. The mixture is then compressed to one-third of its original volume whilst still warm. It is finally sprayed with water to cool and harden.—W. P.

Carbonisation of fuel by vertical coke ovens and the like. W. E. Davies, Penygraig, S. Wales. Eng. Pat. 136,880, 19.12.18. (Appl. 21,239/18.)

THE coking chamber, which is discharged from below, is surrounded by a band of flues. The flues are triangular, heart-shaped, or oval in section, and are in sets of three vertical flues, one flue being a heating flue and the others waste heat flues, the three being so connected together that heating gases having traversed the heating flue pass directly through both the waste heat flues. The waste gases are collected in horizontal flues. By means of horizontal perforated diaphragms, at suitable distances apart, the heating gases are made to travel against the wall of the oven chamber. A sheet of impermeable metal may be placed between double heating walls and between the stages of heating flues to prevent diffusion of the gases. The temperature of the centre of the oven may be controlled, or secondary reactions may be produced by introducing gases or vapours at the top or bottom of the flues for withdrawing volatile products, by partially or completely forcing the gases into the body of the charge and withdrawing the products of reaction by suction, maintained continuously or intermittently. The oven may be operated under a

pressure within the carbonising chamber between 15 inches mercury vacuum and 100 atmospheres pressure, and at any temperature between 200° and 1400° C.—W. P.

Coke ovens. W. P. Thompson, Liverpool. From Fours et Proc. Mathy. Soc. Anon., Liège, Belgium. Eng. Pat. 137,905, 4.6.19. (Appl. 14,105/19.)

The coke ovens are heated by surface combustion methods. Air and gas are mixed in a passage beneath each retort, and then pass into vertical flues packed with porous fireproof material. The hot gases released from the upper part of these flues are brought by other like flues not packed with porous material into a recuperator serving for heating air or gas. Two recuperators of this kind are arranged under each retort.—W. P.

Steaming gas retorts; Appliances for —. A. E. Whitcher, Burgess Hill, Sussex, H. K. Hiller, and The Hewitt Construction Synd., Ltd., London. Eng. Pat. 136,910, 21.12.18. (Appl. 21,637/18.)

A COMBINED superheater and steam distributor is described. In order to bring the steam into contact with the incandescent carbon at the highest possible degree of superheat, the pipe coil conveying the steam is brought through the back or stop end of the retort. The superheater coil is placed in one of the waste gas flues, and the steam on passing from this may be still further heated in an expansion chamber. From this chamber a fan-like series of openings conducts the steam in regular streams into the coal undergoing distillation.

—W. P.

Water-gas; Manufacture of —. Comp. pour la Fabrication des Compteurs et Matériel d'Usines à Gaz, Paris. Eng. Pat. 113,271, 21.1.18. (Appl. 1159/18.) Int. Conv., 31.1.17.

THE producer consists of two parts of equal height, the lower part cylindrical in shape and the upper a double truncated cone, the bottom of which has a materially smaller cross-section than that of the lower cylinder. Air is blown alternately through each part, first from the bottom of the grate, and then into the middle of the producer as soon as carbon monoxide flames appear in the producer throat. In this way a high and practically uniform temperature is maintained throughout the whole of the fuel, and formation of excess of carbon monoxide during the blowing is avoided. The process is more particularly suitable for small installations.—W. P.

Coal; Method of treating caking — before use in the Mond gas producer for the recovery of the nitrogen. Ehrhardt und Schmer Ges.m.b.H., Saarbrück. Ger. Pat. 301,602, 18.11.16.

BEFORE treatment in the Mond producer the coal is freed from tarry matter by preheating to a temperature below that at which the greater part of the nitrogen is removed, i.e., to about 450° C. By this means the caking property of the coal is almost completely destroyed and very little nitrogen is lost, as formation of ammonia begins only at about 500° C.—L. A. C.

Petroleum; Process of and apparatus for cracking —. F. C. Ruff, Los Angeles, Assignor to By-Products Manufacturing Co., San Francisco, Cal. U.S. Pat. 1,325,582, 23.12.19. Appl., 15.1.17.

PETROLEUM preheated to below its cracking temperature is mixed in a closed chamber containing a catalyst with steam heated to above the cracking temperature. The gaseous products are scrubbed by passage through the liquid residue.—L. A. C.

[Hydrocarbon oil] distillates; Process of condensing and treating —. R. Fleming, Westfield, N.J., Assignor to The Richard Fleming Co. U.S. Pat. 1,325,668, 23.12.19. Appl., 25.3.18.

Hydrocarbon oil vapour from a still is passed through a dephlegmator to the jet of an injector, where water is drawn in and mixed with the oil vapour under pressure. The mixture passes to a chamber where gas and liquid are separated, and the bottom of this chamber is connected by a pipe to the top of an oil and water separator at a higher level. The oil collecting at the top of the separator then passes to a storage tank. The mixture of oil vapour and water produced by the injector is subjected to sufficient back pressure due to the head of liquid in the oil and water separator to prevent any material expansion before reaching the gas separator.—W. F. F.

Oils [gasoline]; Improving —. A. M. McAfee, Port Arthur, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,326,072, 23.12.19. Appl., 26.6.18.

HIGH-GRADE gasoline is prepared by treating cracked gasoline at a temperature below its end boiling point with sufficient aluminium chloride to convert unsaturated compounds into low-boiling saturated compounds.—L. A. C.

[Mineral] oils; Apparatus for separating composite —. F. E. Van Tilburg, Minneapolis, Minn. U.S. Pat. 1,326,230, 30.12.19. Appl., 18.2.18.

A MIXTURE of oils is vaporised, and the vapour is led into an expansion chamber containing a central vertical tube which passes directly through the top wall of the chamber and is connected to the vapour condenser. The vertical tube is provided with a relatively small aperture just below the top of the expansion chamber, and can be sealed at its lower end.—L. A. C.

Briquette presses. K. K. Koffroth, Amsterdam, Holland. Eng. Pat. 122,190, 4.1.19. (Appl. 270/19.) Int. Conv., 14.11.17.

Petroleum products; Manufacture of high-grade low-boiling —. A. M. McAfee, New York, Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,326,073, 23.12.19. Appl., 9.1.15.

Hydrocarbons etc. Ger. Pats. 314,745—7. See III.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Carbonaceous material; Apparatus for the distillation of solid —. C. D. Burney, London. Eng. Pat. 136,585. (Appls. 14,176, 31.8.18, and 19,177, 21.11.18.)

COAL, cannel, lignite, shale, peat, etc., are distilled at a low temperature in a horizontal retort by passing hot gases from a furnace through a conduit surrounded by the material. The raw material is fed continuously into one end of the retort, and is slowly moved through it by means of a rotating helical conveyor, the helical blade of which is hollow, and is mounted on a hollow shaft. The hot gas is passed into the hollow shaft and thence into the hollow blade at one or more points. The material is heated by conduction through the wall of the conveyor, and the hot gas passes through the retort in a direction opposite to that of the material. The variation in temperature along the length of the retort may be controlled by varying the velocity of the hot gas through the conveyor

or by varying the inlet pressure. An archimedean screw is provided with its blade intermeshing with the blade of the conveyor, so that the material in the retort may be broken up by rotating the screw. The gaseous products of distillation are withdrawn at various points along the length of the retort, and are passed to condensers. The waste gas from the conveyor may be used for preheating the air and gas which are supplied to the burners of the furnace.—W. F. F.

Low temperature distillation of fuel. Merz and McLellan, London, A. C. Michie, Newcastle-on-Tyne, and E. G. Weeks, Monkseaton. Eng. Pat. 136,868, 20.11.18. (Appl. 19,083/18.)

MEANS are provided for heating each charge of incoming fuel, before it is fed to the retort, to a temperature above the temperature of condensation of the distillate but not high enough to cause any appreciable decomposition of the fuel. In this way the binding together of the fuel is prevented during the continuous gasification of fuel at comparatively low temperatures (500° C.) when blowing through superheated steam or other heated gases.—W. P.

Decolorizing vegetable carbon; Manufacture of —. C. E. Eastick, South Woodford, Essex, and S. P. Eastick, London. Eng. Pat. 136,873, 16.12.18. (Appl. 20,971/18.)

ANY vegetable matter or carbonaceous matter obtained from vegetable matter is finely comminuted, moistened, and then carbonised at a high temperature out of contact with air and without addition of other substances. The decolorising power of the product may be increased by washing out the ash with hydrochloric or other acid.

—W. F. F.

Arcs employed in searchlights, projection apparatus, and arc lamps; Method of arrangement, formation and coloration of one or more —. R. Mylo, Charlottenburg. Ger. Pat. 301,235, 21.9.16.

CHANNELS are arranged longitudinally at the base of one or more of the several arcs, and these serve for the introduction of gases or gaseous mixtures, chemicals in the form of dust or vapour, etc., under increased or diminished pressure. By these means one or more of the arcs, as desired, can be established and maintained in any definite direction, and, if necessary, coloured. The various gases or gaseous mixtures are caused to have various velocities by providing the channels with different cross-sections. The gases or other chemicals employed for colouring the arc are introduced through the channel lying nearest to the core of the electrode.—J. S. G. T.

Electric arcs; Apparatus for automatic regulation of the velocity with which air or gas or mixtures thereof enter or leave longitudinal channels in electrodes of — under the influence of increased or diminished pressure. R. Mylo, Charlottenburg. Ger. Pat. 301,236, 21.9.16.

IN the case of electrodes such as those referred to in the preceding abstract the supply of air or other gas is controlled by valves which are operated by alterations of voltage or current strength in such manner that the supply of air or gas is dependent upon these variations.—J. S. G. T.

Thermic effect of cathode rays; Method and means for utilisation of the —. A Sinding-Larsen, Vestre Aker, Norway. U.S. Pat. 1,326,794, 30.12.19. Appl. 30.10.18.

SEE Eng. Pat. 121,280 of 1918; this J., 1919, 568 A.

III.—TAR AND TAR PRODUCTS.

Tar; Estimation of "free carbon" in —. H. I. Waterman and F. H. C. Barkhuysen. Chem. Weekblad, 1919, 16, 1251—1257.

ABOUT 10 grms. of tar is weighed out in a hardened filter, which is then placed in a Soxhlet thimble, both filter and thimble having been previously extracted with ether, dried at 100° C., and weighed. The tar is then extracted in a Soxhlet apparatus with a solvent, such as aniline, chloroform, benzene, or glacial acetic acid mixed with toluene. The time of extraction should be 22½ hours. A table is given of results obtained by other methods, which show considerable variations, but the table of the actual results obtained by the authors, although referred to in the text, is omitted.—W. J. W.

Low-temperature coal tars; Properties and uses of the products containing phenols obtained by the direct distillation of —. F. Fischer and W. Glud. Ges. Abhandl. zur Kenntnis der Kohle, 1918, 3, 109—121. Chem. Zentr., 1919, 90, IV., 979—980.

Low-temperature coal tar was distilled over a naked flame, and the following fractions were collected for examination: (1) To 225° C. motor spirit ("Zündöl"); (2) 225°—300° C., "motor oil"; and (3) over 300° C. If the distillation was stopped at 300° C., a soft pitch was obtained containing the whole of the paraffin; by distilling up to 325° C. a hard pitch remained; at 340° C. the pitch began to decompose. The quantity of motor spirit (flash-point below 35° C.) obtained was about 14% of the tar; it was of low viscosity, sp. gr. less than 1, of a brownish-red colour and petroleum-like odour, and, on account of the phenols present, attacked metals somewhat. Tar prepared from a gas-coal from the Lohberg mine gave with good cooling 25—30% of a similar oil. The darker coloured motor oil, 25—30% of the tar, had sp. gr. 0.998, flash-point 60°—65° C., calorific value 8630 cal., viscosity (at 20° C.) 5° Engler, setting point (at rest) 3° C., (with agitation) -12° C. After a second distillation the fraction remaining above 225° C. had a flash-point of 71° C. From the fraction 300°—325° C., 15—20% of the tar, a quantity of paraffin separated equal to about 0.5% of the tar; the viscous residue has but little value as a lubricant on account of the phenol content, but might be added to the motor oil or used for working up the pitch. After separation of the phenols it formed a good lubricant. Pitch from low-temperature tar closely resembles ordinary pitch, but contains less free carbon; it has sp. gr. about 1.2, a normal calorific value, and leaves less coke residue than ordinary pitch.—L. A. C.

Phenols of low-temperature coal tar. I.—Cresols. W. Glud and P. K. Breuer. Ges. Abhandl. zur Kenntnis der Kohle, 1919, 2, 236—256. Chem. Zentr., 1919, 90, IV. 913—915.

LOW-TEMPERATURE tar always contains a large but variable percentage of constituents soluble in alkalis—the so-called "phenols"—the proportion being highest in tars from gas coals and reaching 50% of the tar. Lohberg (Dinslaken) gas coal gave 7—8% of gas liquor and 10% of tar on distillation. The former contained a small quantity of phenolic substances, 0.1% by weight of the coal, but no measurable quantity of ordinary phenol. A trace of catechol could be detected. Phenols appear in the tar fractions distilling above 200° C. and in about the same proportions as the hydrocarbons. The crude "phenols" contain a considerable quantity of water difficult to separate. Partially methylated polyhydroxyphenols were absent, as also ordinary phenol, which is therefore not a product of low-temperature distillation. All three cresols

were identified. In the fractions 220°—245° C. by acetylation and crystallisation of the phenoxycetic acids, it was possible to identify the xylenols and trimethylphenols. By acetylation and fractional crystallisation of the cresoxycetic acids all three cresols were identified. They predominate in fraction 196°—201° C., but in the higher fractions give place to the xylenols which form almost the whole of fraction 215°—220° C. Of the cresols the meta-compound is present in greatest quantity. The yield of cresols was 0.6% of the tar, and the quantity actually present was probably 1—2%. The yield of cresols seems to be just about double that obtained in gasworks carbonisation. That the cresols in the latter process are partly destroyed was confirmed by passing *m*-cresol over coke heated to 850°—900° C. The condensed liquid obtained was about 30% of the quantity taken and contained about one-half phenols and the rest hydrocarbons, mainly benzene. The "phenols" obtained were insoluble in ammonia and ordinary phenol, and *o*- and *p*-cresol could not be identified. It seems therefore that the production of higher phenols rather than the cresol content of low-temperature tar accounts for the formation of carboic acid in gas tar.—H. J. H.

Phenols of low-temperature tar. II.—Catechol. W. Glud. Ges. Abhandl. zur Kenntnis der Kohle, 1919, 3, 66—71. Chem. Zentr., 1919, 9V., 915.

The gas coal (Lohberg) referred to in the preceding abstract was distilled in the absence of steam. From the gas liquor catechol equal to 0.0056% of the coal was recovered and approximately the same quantity was obtained from the tar, which contained about 0.6%. A sample of low-temperature tar obtained from a Saar gas coal in a large scale distillation yielded 1.5% of catechol. By making an experiment on a tar with a known quantity of added catechol it was found that the efficiency of extraction was about 50%. Thus the Lohberg coal can be considered as yielding about 0.02% of catechol, and the Saar coal in large scale practice 0.25%. By the extraction of aqueous salt solutions of catechol with ether or extraction from carbon tetrachloride the loss is small; a 70% yield is also obtained from an ether or tar oil solution by means of calcium chloride and ammonia. Extraction from ether solution with solution of sodium carbonate or ammonia is less satisfactory.—H. J. H.

Thiophene in commercial benzols; Estimation of —. A Meyer. Comptes rend., 1919, 169, 1402—1401.

A MODIFICATION of Denigès' method (this J., 1896, 746). The reagent is prepared by dissolving 50 grms. of mercuric oxide in 200 c.c. of sulphuric acid diluted with 1000 c.c. of water. For the estimation 20 c.c. of this reagent is mixed with 75 c.c. of methyl alcohol and 5 c.c. of the benzol under examination, in a stoppered bottle. The mixture is shaken from time to time, and after 30 minutes is filtered. 10 c.c. of the filtrate is diluted with 20 c.c. of water and then a few drops of nitric acid and 1 c.c. of a 20% solution of iron ammonium alum are added and the whole is titrated with *N*/10 ammonium thiocyanate solution. To allow for the possible presence of acetone in the methyl alcohol a blank estimation is conducted using 5 c.c. of benzene free from thiophene. The two titration readings being *n*, and *n* respectively, the amount of thiophene in one litre of benzol is given by

$$0.01 \times 2000 \times (n - n) \times 0.11. \quad \text{—W. G.}$$

1,2,4-Chlorobenzenedisulphonic acid and its transformation into the symmetrical compound. S. C. J. Olivier. Rec. Trav. Chim., 1919, 38, 351—355.

WHEN the anhydrous barium salt of 1,2,4-chloroben-

zenedisulphonic acid is heated with fuming sulphuric acid for five hours at 300° C. it is for the most part converted into 1,2,5-chlorobenzenedisulphonic acid.—W. G.

Chlorobenzenedisulphonic acid prepared according to the patent of Meister, Lucius, and Bruning; Structure of the —. S. C. J. Olivier. Rec. Trav. Chim., 1919, 38, 356—357.

By preparation and identification of its acid chloride it is shown that the chlorobenzenedisulphonic acid obtained by the sulphonation of *p*-chlorobenzenesulphonyl chloride by the method described in Ger. Pat. 260,563 (this J., 1913, 693) is the 1,2,4-acid.—W. G.

Nitro-derivatives of diphenylamine. C. F. van Duin and B. C. R. van Lempe. Rec. Trav. Chim., 1919, 38, 358—368.

IN an endeavour to establish the position of the two entrant nitro-groups in the preparation of a hexanitrodiphenylamine by nitration of 2,4,6,3'-tetranitrodiphenylamine, the authors have prepared a number of nitro-derivatives of diphenylamine. (See further J. Chem. Soc., 1920, i., 155.) —W. G.

*1,6-Dihydroxynaphthoyl-*o*-benzoic acid and its salts [sweetening agents]; Preparation of —.* Ges. für Chem. Ind. in Basel, Switzerland. Ger. Pat. 311,213, 15.2.16.

By condensing 1,6-dihydroxynaphthalene with phthalic anhydride or phthalic acid in the presence of boric acid, 1,6-dihydroxynaphthoyl-*o*-benzoic acid, of m. pt. 226°—227° C., is obtained as chief product; in the absence of the boric acid, or using other condensation agents, the product consists almost entirely of the phthalein. The acid and its salts are characterised by a sweet taste and should serve as substitutes for sugar and other sweetening agents; the 1,5-isomeride is tasteless. 1,6-Dihydroxynaphthoylbenzoic acid can also be used for the production of dyes, and in some respects is superior to the 1,5-isomeride for this purpose.

—D. F. T.

Hydrocarbons and alkali salts of high molecular carboxylic acids; Manufacture of —. E. Albrecht, Hamburg-Wallhof, R. Koetschau, Hamburg, and C. Harries, Berlin-Grünwald. Ger. Pats. (a) 311,715, 29.3.16, (b) 311,716 and (c) 314,747, 11.6.16.

HYDROCARBONS such as (a) tar products from lignite, shale, peat, or bituminous asphalt, cracked petroleum oils, products extracted from oils by means of sulphur dioxide, esters of the olefines obtained from lignite tar oil, *e.g.*, by the action of sulphuric acid, acetic acid, chloroacetic acid, or the like, or esters obtained by the action of potassium acetate on halogenated petroleum hydrocarbons; or (c) the highly unsaturated acid resins separated from waste acid from mineral oil refining, or the compounds produced therefrom by treatment with water, steam, or lime, or petroleum pitch, are melted with an alkali or with a highly concentrated alkaline solution. (b) The hydrocarbons are heated with an alkaline liquor so that,

by elimination of oil and water, highly concentrated or molten alkali is formed in the melt. Light hydrocarbons of a high degree of purity are formed by the treatment owing to decomposition of certain impurities, and alkali salts of high molecular carboxylic acids are produced simultaneously. The alkali salts, which are readily separated from unchanged alkali, rather well and may be employed as soap substitutes. The alkali melt may be agitated by a current of a gas, which may also assist the reaction, *e.g.*, oxygen accelerates the salt formation, whereas hydrogen raises the purity of the light hydrocarbons. The action is rapid and is often complete in less than half an hour. Increased or reduced pressure may be employed during the fusion process, inactive solvents may be present, or catalysts may be added to accelerate the reaction. Examples: 100 kilos. of gas-oil from lignite and 100 kilos. of potassium hydroxide gave about 30 kilos. of light oil, b. pt. 150°–220° C., 45 kilos. of alkali salts, 35 kilos. of residual oil, and 90 kilos. of unchanged potassium hydroxide; 100 kilos of paraffin gas-oil, the iodine value of which had been raised to about 150 by cracking, gave about 60 kilos. of alkali salts, 35 kilos. of benzol and light oil, b. pt. 80°–220° C., and 15 kilos. of residual oil.—L. A. C.

Anthracene; Production of pure —. P. Leroux, Gennevilliers, Assignor to Soc. d'Eclairage, Chauffage, et Force Motrice, Paris, France. U.S. Pat. 1,326,515, 30.12.19. Appl., 24.8.18.

IV.—COLOURING MATTERS AND DYES.

Hydroxyanthraquinones; Certain metallic derivatives of —. M. L. Crossley. J. Amer. Chem. Soc., 1919, 41, 2081–2083.

COPPER, cadmium, nickel, iron, cobalt, and chromium salts of alizarin, anthrapurpurin or flavopurpurin are formed when the hydroxyanthraquinone is boiled with a salt of the respective metals, anhydrous sodium acetate, and nitrobenzene. The alizarin salts, though slightly soluble in water, dye wool a pale shade of the colour produced when the wool previously mordanted with the metallic salt is dyed with alizarin. The dye is evenly distributed throughout the fibre, and is apparently fast. In view of these facts it is suggested that the formation of an insoluble alizarin lake in a mordanted fibre is accomplished by combined physical and chemical phenomena.—W. G.

Hydroxydianthraquinonyls; Oxidative formation of — from hydroxyanthraquinones. II. Experiments with erythrohydroxyanthraquinone and quinizarin. R. Scholl, E. Schwinger and O. Dischendorfer. Ber., 1919, 52, 2254–2261.

THE formation of tetrahydroxydianthraquinonyl by the action of hypochlorite on an alkaline solution of alizarin does not appear to be an example of a general reaction, but similar cases are encountered with erythrohydroxyanthraquinone and quinizarin. According to Ger. Pat. 167,461 the former when melted with potash yields the hydro compound of a substance, $C_{28}H_{14}O_6$, of unexplained constitution; this is now shown to be 1.1'-dihydroxy-2.2'-dianthra-

quinonyl, since when distilled with zinc dust in a hydrogen vacuum it gives 2.2'-dianthryl and, when heated in carbon dioxide at 500° C., it yields 2.2'-dianthraquinonylene-1.1'-oxide. Quinizarin, according to Ger. Pat. 146,223, is converted by salts of weak acids into two compounds, $C_{28}H_{14}O_8$ and $C_{28}H_{12}O_8$; further investigation proves that only the first of these is a new substance, the second being a mixture of the first and quinizarin. The new substance is shown to be 1.4.1'.4'-tetrahydroxy-2.2'-dianthraquinonyl since it gives 2.2'-dianthryl when distilled with zinc dust and a furan derivative when melted with zinc chloride. The substance $C_{28}H_{14}O_8$ obtained by A. G. and W. H. Perkin (this J., 1889, 112) by the distillation of sodium anthraquinone-2-sulphonate has been distilled with zinc dust, whereby anthracene and 2.2'-dianthryl were obtained, but the result does not throw much light on the constitution of the substance.—H. W.

Benzoketodihydrothiazine; Dyestuffs derived from —. W. Herzog. Ber., 1919, 52, 2270–2274.

BENZOKETODIHYDRO-1.4-THIAZINE reacts with α -isatinanilide in a solvent of high boiling point, such as ethyl benzoate, to yield 2-(benzodihydro-1.4-thiazine)-2-(indole)-indigo (annexed formula), dull, brownish-violet needles with metallic glance, m. pt. above 300° C., which dyes cotton bluish-violet and wool reddish-violet.

2-(Benzodihydro-1.4-thiazine)-2-(thionaphthen-indigo, yellowish silky needles, m. pt. above 300° C., similarly prepared from thionaphthenquinone-anilide, and 2-(benzodihydro-1.4-thiazine)-3-(indole) indigo, orange-red silky needles, m. pt. about 270° C., have little affinity for the textile fibres. The inferiority of the substances as dyes in comparison with Indigo Blue and Thioindigo Red is readily interpreted according to the Claass hypothesis (this J., 1916, 1150) since they contain only one quinonoid indogen, whilst the latter dyes contain two such groups.—H. W.

Gentian Violet. Crossley. See XIXB.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Fabrics; Determination of the water resistance of —. F. P. Veitch and T. D. Jarrell. J. Ind. Eng. Chem., 1920, 12, 26–30.

THE two following tests are recommended as being the most trustworthy of several investigated. *Funnel test.*—A piece of the fabric, 1 ft. square, is crumpled in the hand, immersed in water at 21°–27° C. for 24 hrs., being taken out and crumpled several times during this period, then dried at 45° C. for 24 hrs., and hung up in the laboratory for 18 hrs. These operations are repeated. The fabric is then once more crumpled, straightened out, placed on a piece of absorbent paper of the same size, the two are folded together in the usual way to form a filter and placed in a 6-in. glass funnel having an angle of 60°. Water at 21°–27° C. is poured into the filter to a depth of exactly 4 in. (this equals 500 c.c.), and this depth is maintained by the ordinary device of an inverted flask filled with water. A graduated cylinder is placed under the stem of the funnel. The time is noted when the paper under the fabric begins to wet, when it is entirely wet, when the first drop passes

into the cylinder, and the quantity of water collected in the latter in 1, 3, 6, and 24 hrs. Note is also made of the time and extent to which the fabric becomes wet above the water level. The water resistance is rated very high when the fabric above the water level and the paper both remain dry after 24 hrs.; high if the paper becomes just wet and the fabric above the water level remains dry; medium if water drips through at the rate of 5–25 c.c. in 6 hrs., or 25–50 c.c. in 24 hrs., and low if the water dripping through exceeds 75–200 c.c. in 6 hrs., or 150–300 c.c. in 24 hrs. *Spray test*.—The piece of fabric used for the funnel test is dried at 45° C. for 24 hrs., and hung up in the laboratory overnight; it is then clamped loosely in a frame which is fixed at an angle of 45° in a trough, and tap water is allowed to fall from a height of 6 ft. on the central portion of the fabric, covering an area of about 8 in. in circumference, for 24 hrs. The water tap has a 2½ in. spray nozzle having 25 holes each 1.9 mm. in diameter, and the water flow is 1000 c.c. per min. The under side of the fabric is examined periodically. The water resistance is rated as follows:—High, if the under surface remains dry for 7 hrs. but is damp in 24 hrs.; medium, if the under surface remains dry for 1 hr. but is wet in 3 hrs.; low if it remains dry for 5 mins. but is wet in 30 mins. The crumpling, wetting, drying, re-wetting, and re-drying of the fabric are done with the object of removing the temporary resistance of new fabric and to imitate, to some extent, the conditions of actual service.—W. P. S.

Sulphite-cellulose waste liquor as fertiliser. Bokorny. See XVI

Nitrogen in celluloid. Nicolaidot and Vourloud. See XXII.

PATENTS.

Wood-pulp digester liquor; Recovering valuable constituents from —. H. K. Moore, Berlin, N. H., Assignor to Brown Co., Portland, Me. U.S. Pat. 1,324,920, 16.12.19. Appl., 14.8.13.

The liquor is concentrated, burnt, extracted with water, and re-causticised.—L. L. L.

Cellulose acetates; Production of solutions of —. F. Steimmig, Hannover. Ger. Pat. 307,075, 3.6.17.

FURFURAL is used as solvent either alone or with other organic solvents in which cellulose acetate is not completely soluble. The acetone-soluble form of cellulose acetate, and also the chloroform-soluble form, yield satisfactory solutions. The solvent action of furfural is not reduced by the admixture of other liquids in which cellulose acetate is only partially soluble, e.g., ethyl acetate, methyl alcohol, ethyl chloride, benzene, and toluene.—H. J. H.

Paper-stock; Process and apparatus for seasoning and rectifying —. G. E. Poggel, Louisville, Ky. U.S. Pat. 1,325,044, 16.12.19. Appl., 24.9.17.

A PROCESS of seasoning and rectifying paper stock consists in blowing currents of heated air upwards between the sheets which are suspended within an enclosure. After passage between the sheets the air is again made to travel in the same cycle.

—L. L. L.

Paper machines; Arrangement for ensuring the movement of the guide rollers of the long sieve of —. Farb. vorm. Meister, Lucius, and Brüning, Höchst. Ger. Pat. 308,372, 12.5.16.

The guide rollers are provided with rings of elastic material such as rubber or felt, which press lightly into the sieve and ensure their sympathetic movement, thereby preventing friction and rapid wear due to the usual tendency of the rollers to remain stationary.—D. F. T.

Paper, pasteboard, cellulose, and similar material; Arrangement for drying — in continuous strips. H. Mallick, Gross-Sachsen. Ger. Pat. 309,543, 16.2.17.

The bands of paper or other material are passed over steam-heated cylinders and at the same time subjected to a blast of air of a different temperature from the cylinder. By arranging the dryer in several sections filled with air at different temperatures it is possible to introduce into any section the air issuing from a previous section.—D. F. T.

Thread, twine, or cord; Manufacture of — from paper or like material. J. C. Grant, Barnes. Eng. Pat. 136,611, 11.12.18. (Appl. 20,894/18.)

Artificial silk; Apparatus employed in manufacture of —. J. Clayton, Coventry. Eng. Pat. 136,784, 5.8.19. (Appl. 19,298/19.) Addition to Eng. Pat. 136,769, 16.6.19.

Drying machine cylinders [for fabrics, paper, etc.]; Dull-head bearings for —. H. Holt, St. Annes-on-Sea, and J. K. Malone, Bury. Eng. Pat. 137,209, 23.4.19. (Appl. 10,098/19.)

Celluloid; Manufacture of unflammable —. H. Dreyfus, Basle, Switzerland. U.S. Pat. 1,325,931, 23.12.19. Appl., 15.2.18.

See Eng. Pat. 111,301 of 1918; this J., 1918, 687 A.

Paper pulp; Treatment of —. J. A. De Cew, Montreal, Canada, and R. J. Marx, London. Eng. Pat. 137,207, 15.4.19. (Appl. 9576/19.)

See U.S. Pat. 1,300,357 of 1919; this J., 1919, 497 A.

Turkey-red oil substitute. Ger. Pat. 310,541. See XII.

Saponin from sulphite-cellulose waste liquors. Ger. Pat. 311,339. See XX.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Nopps; Dyeing of —. A. Reyl. Färber-Zeit., 1919, 30, 252–254.

THE usual method of dyeing nopps in woollen goods consists in topping off the vegetable fibres by means of direct cotton colours, or the dyeing of the material in a neutral bath with neutral wool colours along with direct cotton colours. In the case of several pieces which could not be dyed level the defect was proved to be due to the presence of fatty matter on the cotton. The material requires either wet or dry scouring to remove the saponifiable or unsaponifiable fat prior to dyeing.—L. L. L.

Aniline Black fast to reducing agents. A. Ehrenzweig. Deuts. Baumwollind., 1919, 1, 71. Chem.-Zeit., 1919, 43, Rep., 316.

AN Aniline Black unobtainable by reducing agents is produced by means of compounds of chloric acid, 2–8 parts of aniline glycolate and tartrate, and 1 part of *p*-phenylenediamine, without chromates and salts of heavy metals. A thiocyanate is added to protect the fibre, and this also takes part in the formation of the black. Dry steam at 100°–120° C. must be employed. The elimination of the chromo and soap baths, which are replaced by washing, is advantageous in dyeing articles by the Prud'homme process. The method is applicable to dyeing half-wool and half-silk.—L. A. C.

ERRATUM.—This JOURNAL, Jan. 31, 1920, p. 61 A, col. 1, "*Tinctorial properties of anthocyanins and certain related compounds*," by A. E. Everest and A. J. Hall. In lines 3-4 and 8 of the abstract, for "anthocyanins" read "anthocyanins."

Metallie derivatives of hydroxyanthraquinones. Crossley. See IV.

PATENTS.

Ageing machines. Calico Printers' Assoc., Ltd., G. Turner, and E. A. Fournieux, Manchester. Eng. Pat. 136,507, 28.8.19. (Appl. 21,134/19.)

Noxious gases are often given off in ageing machines which may hinder the proper development of, or otherwise interfere with, the colour. This is more particularly the case with Aniline Black. The usual method of ventilating these machines consists in providing openings generally on the top or at the back of the machine, these openings being connected to a trunk or shaft leading to the open air. By this method there is no ventilation between the folds or laps of the fabric, and the removal of gases is thus incomplete. This defect is overcome by providing suction elements between the folds or laps of fabric and removing the vapours or gases as they are generated.—L. L. L.

Paper yarns and fabrics; Method for dyeing — with substantive colours. Chem. Fabr. Coswig-Anhalt. Ger. Pat. 310,965, 15.3.18.

In addition to oxidising agents there are introduced into the dyeing bath such substances as boric acid, acetic acid, ammonium chloride, weak organic acids, ammonium salts of phosphoric acid, etc. These aid the transfer of the colour to the material and the process, which is applicable with all substantive dyes, yields an open, soft material with bright colour.—D. F. T.

Washing cloth made from yarn treated with mineral oil; Process for —. A. Pinagel, and Aachener Chem. Werke für Textilindustrie, Aachen. Ger. Pat. 311,403, 19.7.16.

The cloth is first immersed in an alkaline saponin solution and an alcoholic fulling oil containing only a small percentage of fat is added, and then the cloth is washed in the usual way. Whereas by the existing methods goods treated with mineral oil require 3–4 kilos. of the best fulling soap containing 60% of fat, after preliminary treatment with saponin solution it is only necessary to use $\frac{1}{2}$ –1 kilo. of a fulling material containing 15% of fat to achieve a satisfactory washing.—H. J. H.

Wool fibres; Stripping colour from —. F. Kollm. Berlin. Ger. Pat. 314,852, 21.3.18.

DETERIORATION of wool fibres during the stripping of colour therefrom, by means of, for instance, formic acid and "decolin," is considerably reduced by addition of the decomposition products of proteins, such as protalbinic acid, lysalbinic acid, and the like, to the bath.—L. A. C.

Turkey-red oil substitute. Ger. Pat. 310,541. See XII.

Detergents. Ger. Pat. 314,590. See XII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Formation of — from nitric oxide. A. Sanfourche. Bull. Soc. Chim., 1919, 25, 633–655.

A STUDY of the oxidation of nitric oxide by dry air over the temperature range 50° C. to 600° C. showed that with an insufficient supply of air it is always nitrogen trioxide which is formed, both at temperatures below 0° C. and at the ordinary temperature. With an excess of air the final term of oxidation is the peroxide at temperatures below 250° C., the formation of the peroxide being extremely rapid at temperatures below 0° C., and the

velocity diminishing with rise in temperature. At temperatures above 250° C. some nitrogen trioxide, is always obtained, the trioxide becoming more and more abundant as the temperature rises, until at about 600° C. the trioxide is the only oxide formed. At temperatures below 0° C. the direct combination of nitric oxide with nitrogen peroxide to form nitrogen trioxide is possible. It is not the peroxide but the trioxide which acts as an intermediary in the formation of nitric acid from nitric oxide, at any rate in the usual installations where the contact of nitrous vapours, air, and water is permanent. If, however, means were devised periodically to assure total oxidation to the peroxide before the action of the water occurred, the productiveness of the installation would be increased. This may be done by the use of alternating oxidation towers and absorption towers. On the other hand, the oxidising action of strong nitric acid on nitrogen trioxide shows that it is not possible to prepare by this means an acid stronger than 50%, since above this concentration the nitric acid is reduced with the formation of nitrogen peroxide. A higher concentration could probably be reached if, whilst assuring the total oxidation of the nitrous vapours, nitrogen peroxide and not the trioxide was allowed to act on the aqueous nitric acid.—W. G.

Nitrogen peroxide; Dissociation constant of —. E. Wourzel. Comptes rend., 1919, 169, 1397–1400.

DIRECT measurements at temperatures between 0° C. and 86.5° C. show that the value of the dissociation constant, K, is given by the equation, $\log K/T = 8.9908 - 2810.5/T$, from which the heat of polymerisation is calculated as 12,850 cal., exact to within 0.5%. —W. G.

Ammonium sulphate; Manufacture of — from gypsum. D. H. B. Wride. Chem. Age, 1920, 2, 32–33.

A PROCESS for the utilisation of gypsum for the production of sulphuric acid is described in Eng. Pat. 124,842 of 1919, in which a mixture of gypsum and water is treated with ammonia and carbon dioxide and converted into ammonium sulphate and calcium carbonate. These are separated by filtration, and the ammonium sulphate is recovered by evaporation and heated with ferric oxide, when ammonia gas and ferric sulphate are formed; the former is returned to the gypsum-treating plant and the latter is decomposed in another furnace into sulphur trioxide and ferric oxide. The first part of the process is capable of being utilised for the production of ammonium sulphate, and is specially applicable to the ammonia obtained by the Haber synthetic process, as the carbon dioxide required is obtained as a waste product in the preparation of the hydrogen. Difficulties have arisen in connection with the filtration of the calcium carbonate mud, which in the presence of small quantities of silica and alumina becomes very slimy and difficult to wash, but suction filters of the leaf type such as are used in gold extraction have given good results. There are considerable deposits of gypsum in Westmorland, Cumberland, and Derbyshire, and experiments were carried out early in 1919 in the laboratory of the Research Department of the Ministry of Munitions. The fresh gypsum was brought into contact with the nearly completely converted ammonium carbonate solution on the counter-current principle. No trouble was experienced with the filtration and the chalk mud after washing tested NH_3 0.62%, SO_4 1.28%, CO_2 42.11%, and moisture 40.81%. 95% of the ammonia was recovered, 97% of which was obtained as ammonium sulphate. The reaction is an exothermic one, and arrangements must be made for cooling the apparatus.—W. H. C.

Sulphurous acid; Neutralisation curve of —. I. M. Kolthoff. Chem. Weekblad, 1919, 46, 1154—1163.

A VALUE of 1×10^{-7} is given for the second dissociation constant of sulphurous acid, calculated from the degree of hydrolysis of solutions of sodium sulphite. The hydrogen ion concentration of a 0.1 mol. solution of sodium bisulphite was found to be 3.3×10^{-2} . A curve is given showing the neutralisation of sulphurous acid to sulphite. In titrating sulphurous acid accurate results can only be obtained if, after coloration of the phenolphthalein, an excess of barium nitrate is added and the titration then continued.—W. J. W.

Chlorates; Iodometric estimation of —. I. M. Kolthoff. Pharm. Weekblad, 1919, 56, 460—465.

HIGH results are obtained in the direct iodometric estimation of chlorates owing to oxidation by atmospheric oxygen. Rupp's method (this J., 1918, 205 A) is accurate, but smaller quantities of reagents are sufficient, whilst by the use of ferrous sulphate still smaller quantities may be employed.—W. J. W.

Iodides; Estimation of —. I. M. Kolthoff. Pharm. Weekblad, 1919, 56, 1029—1035.

A COMPARISON of existing methods was made with the same solution of potassium iodide. Winkler's method (this J., 1918, 390 A) gives good results only in absence of bromide. The presence of small quantities of bromide does not affect the results obtained by those methods (Volhard, Vincent, Richard) in which hydrogen iodide is oxidised to iodine and the latter estimated; but after addition of tartaric acid in Richard's method the solution should be allowed to stand for 2 to 3 minutes. By adding benzoic acid and potassium iodate to an iodide solution, boiling to eliminate iodine, and then adding potassium iodide and sulphuric acid, and titrating back with thiosulphate, good results are obtained even in presence of bromide.—W. J. W.

Potassium thiocyanate; Photochemical oxidation of —. D. Ganassini. Boll. Chim. Farm., 1919, 58, 457—463.

UNDER the influence of sunlight solutions of certain concentrations of potassium thiocyanate, especially those of the pure salt free from traces of ferrous salts, are oxidised by atmospheric oxygen with separation of a yellow precipitate of pseudo-cyanogen sulphide (CNS)₂. In addition to this occasional product, hydrocyanic and sulphuric acids, carbon dioxide, and ammonium salts are formed as constant products of the photochemical decomposition of the thiocyanate: $12\text{KCNS} + 12\text{O}_2 + 6\text{H}_2\text{O} = 6\text{K}_2\text{SO}_4 + 3\text{HCN} + 3\text{CO}_2 + 3\text{NH}_3 + 2(\text{CNS})_2$; an unstable peroxygenated compound, possibly analogous to Caro's acid, is also formed as an intermediate product. Normal, decinormal, and centinormal solutions of potassium thiocyanate undergo decomposition; the two last do not, however, deposit pseudo-cyanogen sulphide and do not alter appreciably in titre within certain time limits. (See also J. Chem. Soc., Mar., 1920.)—T. H. P.

Sodium zincate. Equilibria in the system Na₂O-ZnO-H₂O. F. Goudriaan. Proc. K. Akad. Wetensch., 1919, 22, 179—189.

IN the system Na₂O-ZnO-H₂O there appear as solid phases: zinc oxide, sodium zincate Na₂O.ZnO.4H₂O, and the monohydrate of sodium hydroxide. Sodium zincate forms incongruent solutions from which at the concentration 1 part sodium hydroxide to 2 parts of water zinc oxide separates. Gelatinous zinc hydroxide is a phase of varying water content from which it is not possible to remove all adsorbed material.—J. F. S.

Dolomites; Comparison of —. A. Rothrock and J. B. Shumaker. Chem. News, 1920, 120, 29—31.

TYPICAL dolomite, CaCO₃.MgCO₃, probably never occurs in nature, one or other constituent being partially replaced by other substances. Analyses of thirteen different minerals from various sources are given. The content of calcium carbonate ranged from 27.01 to 96.25 and of magnesium carbonate from 1.15 to 67.91. It is concluded that many minerals and rocks which may fairly be classed as dolomites vary greatly in composition and many so-called dolomites are really limestones.—A. B. S.

Combustible matter in silicate and carbonate rocks; Determination of —. A. C. Fieldner, W. A. Selvig, and G. B. Taylor. U.S. Bureau of Mines. Tech. Paper 212, 1919. 18 pages.

LISSNER's method (this J., 1910, 112), viz., digestion of the material with hydrofluoric and hydrochloric acids, and combustion of the insoluble residue, was found to give abnormally high results for organic hydrogen in rocks containing small amounts of combustible matter, owing to the presence of a hydrous acid aluminium fluoride in the dried, insoluble residue. In the following modification of Lissner's process the presence of this compound in the residue is obviated by adding an excess of hydrochloric acid after the silicates are decomposed, and by avoiding evaporation to dryness. 0.2—1.0 gm. of the finely divided (silicate) rock is heated for 10 mins. with 15 c.c. of concentrated hydrochloric acid in a platinum dish, then 20 c.c. of strong hydrofluoric acid is added, and the contents of the dish are maintained at incipient boiling until the inorganic matter appears to be decomposed (30 mins.—2 hrs.); sufficient of the mixed acids (in the same proportions) is added from time to time to maintain the volume of the liquid above 15 c.c. After evaporation of the solution to 15 c.c., 25 c.c. of concentrated hydrochloric acid is added, the liquid being boiled to re-dissolve any acid aluminium fluoride, then diluted with an equal volume of hot water, boiled again, and filtered, while hot, through ignited asbestos or platinum sponge. The residue is washed with hot water until free from chlorides, placed, with the filter, in a porcelain or platinum boat, dried for 2 hours at 105° C., and transferred direct from the drying oven to the tube of the combustion furnace. It is important to avoid evaporation below 15 c.c., and, if the digestion is conducted on a hot plate, the temperature must not exceed that of incipient boiling. Samples composed mainly of organic matter are best treated on a water bath. When these precautions are observed, the loss of organic carbon and hydrogen during digestion is practically negligible, even from pure bituminous coal. Calcareous rocks require preliminary treatment with dilute hydrochloric acid to remove calcium carbonate, &c., before the process is applied; the insoluble residue is collected on ignited asbestos, which is then heated with hydrochloric and hydrofluoric acids, as described. In a series of analyses of shales, clays, and slates from coal mines, the ratios of organic hydrogen to organic carbon found by this method varied between 1:7 and 1:17 and the combined water between 2.5 and 5.7%.

—W. E. F. P.

Minerals; Colloidal colouring substances in —. C. Doelter. Kolloid-Zeits., 1920, 26, 23—27.

THE colour of many minerals is due to small quantities of impurity which may be the same in differently coloured minerals. The nature of the colour depends on the size of the particles of the impurity. Changes in the colour effected by heating or by the action of radium rays are due to change in the dimensions of the particles.—J. F. S.

Metallic oxide sols; Physico-chemical analysis of —. W. Pauli. *Kolloid-Zeits.*, 1920, 26, 20—23.

A POLEMICAL article against Zsigmondy's theory of solutions and suspensions.—J. F. S.

Rhodium; Behaviour of hydrogen towards —. A. Gutbier and O. Maisch. *Ber.*, 1919, 52, 2275—2280.

THE experiments were performed in the same manner as with palladium, iridium, and platinum (this J., 1913, 661; 1919, 679, 680). The deep black modification, rhodium black, is able to absorb far more hydrogen than any other form. The maxima of hydrogen absorption amounted to 180 volumes at 190° C. for the grayish-black form, 165 volumes at 40° C. for the slightly grayish-black variety, and 206 volumes at 0° C. for the deep-black modification. (The varieties are obtained in the order given by the reduction of sodium rhodium chloride by hydrazine in faintly acid, neutral, and ammoniacal solution respectively; the purest preparations, dried in a vacuum over phosphorus pentoxide, contained about 3.0% H₂O and 0.3% O.) The absorption of hydrogen by rhodium is much less than by palladium and corresponds to that observed with platinum. Spongy rhodium, like spongy platinum, only absorbs small amounts of hydrogen.—H. W.

ERRATA.—This J., July 31, 1919, p. 498 A, line 21 from top, for "100" read "100 grms.," and for "25 grms." read "25 c.c."

PATENTS.

Hydrochloric acid; Production of — from sodium bisulphate and salt. E. Teisler, Delna. *Ger. Pat.* 300,723, 23.5.16.

SOLID substances resistant to hydrochloric acid, e.g., metallic sulphates, or various forms of carbon, are added to the reaction mixture. Segregation of the mixture due to the fusion of the sodium bisulphate is thereby checked and hydrogen chloride is evolved freely at 150° C., the residue forming a porous mass practically free from chloride and free sulphuric acid.—D. F. T.

Radium; Production of compounds of —. H. O. Hedström, Djursholm, Sweden. *Eng. Pat.* 136,768, 6.6.19. (Appl. 14,439/19.)

RADIUM compounds are extracted from minerals or the like by means of liquid sulphur dioxide; the solvent is removed by evaporation, and the extract treated for the production of radium-barium compounds. If oil or other carbonaceous material is present in the mineral, e.g., Swedish alum slates (shales) of the Cambrian formation, or "kolm," this is first removed by burning or distillation. —L. A. C.

Ammonium sulphate; Production of —. C. W. Bailey, H. S. Denny, and W. H. H. Norris, Langwith. *U.S. Pat.* 1,325,605, 23.12.19. *Appl.*, 2.12.18.

NITRE-CAKE, ammonium sulphate, and sodium sulphate are mixed in the presence of water; a portion of the sodium sulphate is separated, and the solution is used without the addition of acid for absorbing ammonia from gases containing the same.—L. A. C.

Leucite; Recovering potash from —. *Treatment of felspar, leucite, and the like.* F. A. Rody, Newark, N.J., Assignor to Metallurgical Co. of America, New York. *U.S. Pats.* (A) 1,325,881 and (B) 1,325,882, 23.12.19. *Appl.*, 18.5.15.

LEUCITE or the like is fused and the fused product is digested (A) under pressure with a solution of sodium salts, or (B) with a solution of easily soluble sodium and potassium salts. The strength and constitution of the solutions are so adjusted that the sodium in solution replaces potassium present in the leucite with a corresponding increase of the amount of potassium salts in the solution.—L. A. C.

Cyanates; Production of — soluble in water. J. D. Riedel A.-G., Berlin-Britz. *Ger. Pat.* 314,629, 7.1.19.

CHLORINE or bromine is passed into concentrated alkaline solutions of cyanides. No appreciable quantity of halogen compounds of cyanogen is produced. Sodium cyanate is formed and separates out in a form suitable for technical and pharmaceutical purposes.—H. J. H.

Inert rare gases; Production of — in a state of purity. R. Brandt, Ludwigshafen. *Ger. Pat.* 314,907, 2.11.16.

THE inert gases are separated from gaseous mixtures by the action of calcium, calcium nitride, or alloys of calcium with magnesium or aluminium. The reagent is previously heated to 200°—650° C. to free it from adherent gases and vapours.

VIII.—GLASS; CERAMICS.

PATENT.

Casting pottery and like articles. B. J. Allen, Blythe Bridge, Staffs. *Eng. Pat.* 136,701, 6.2.19. (*Appl.* 2956/19.)

INSTEAD of using a separate vacuum chamber for each mould, as described in *Eng. Pats.* 110,649 and 111,643 (this J., 1917, 1274; 1918, 58 A), one iron

chamber is used and into it are placed moulds of different sizes suspended in horizontal rows or carried on rolled steel girders. Each mould is provided with a separate funnel through which it is filled. The air in the interior of the chamber is then exhausted by means of a vacuum pump, as in the earlier patents.—A. B. S.

IX.—BUILDING MATERIALS.

Timber preservatives. Falck. See XIXu.

PATENTS.

Porous building and insulating bodies of "moler" (kieselguhr, diatomaceous earth) and the like; Production of —. I. N. S. Frydenlund, Frederiksberg, Denmark. Eng. Pat. 123,992, 4.3.19. (Appl. 5358/19.) Int. Conv., 5.3.18.

HEAT-INSULATING and sound-deadening materials are made by mixing organic filling materials, such as the pith of *Helianthus annuus* (sunflower) with diatomaceous earth and then heating the material until all the organic matter is destroyed. The swelling and other disadvantages of other organic filling materials are avoided, as the pith is more compressible.—A. B. S.

Artificial stones [abrasive wheels]; Manufacture of —. H. Sefton-Jones, London. From White Heat Products Co., West Chester, Pa., U.S.A. Eng. Pat. 136,580, 18.3.18. (Appl. 4771/18.)

ARTIFICIAL stones and grinding wheels are made by mixing a natural mineral substance, such as silica, corundum, or a mixture of bauxite and rutile which has been fused and allowed to crystallise, or artificial crystalline mineral substances, such as carborundum, or alundum, with a binder composed of sodium silicate and glass and heating rapidly until the binder is fused. It is claimed that by this means the articles produced do not crack so readily and require a much shorter period of heating than when clay or other binders are used.—A. B. S.

Building brick or block, and method of manufacturing same. C. C. Millard and R. A. Robertson, London, and C. J. Cooper, Chorley Wood, Herts. Eng. Pat. 136,742, 28.3.19. (Appl. 7832/19.)

BUILDING bricks or blocks are made of clinker and/or furnace ashes, with or without brick rubble or burnt clay, and with lime and Portland cement as binders. The clinker, ashes, and burnt clay are reduced to a fine state, mixed with Portland cement and then with lime which has previously been slaked with three times its volume of water so as to form a moist but not slimy mass. This material is moulded into the desired shape and the blocks or bricks are then allowed to dry in the air. The burnt clay makes the bricks waterproof and prevents expansion in the material.—A. B. S.

Cement and soluble potassium compounds; Process of obtaining —. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co. Reissue 14,773, 23.12.19, of U.S. Pat. 1,186,522, 6.6.16. Appl., 5.10.18.

See this J., 1916, 843.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Rust-proofing iron and steel; Phosphatic coatings for —. L. E. Eckelmann. Chem. and Met. Eng., 1919, 21, 787–789.

RECENT phosphatic rust-proofing processes do not alter appreciably the dimensions or sharpness of

machined articles, and, due to the low temperatures used, the physical properties of tempered steel are in no way affected. In the process known as "Parkerising" Coslett's solution (Eng. Pat. 8667 of 1906; this J., 1907, 207) is modified by adding an oxidising agent, such as manganese dioxide, to a 0.75% solution of orthophosphoric acid containing ferrous phosphate, which becomes partly oxidised to the ferric state after continued agitation and boiling. The coating formed on iron during the boiling in the phosphoric acid solution is of a uniform dark-grey colour, which varies in intensity according to the surface treatment of the metal previous to immersion. The treated metal, after careful drying, is dipped into a paraffin oil mixture, which changes the coating to a deep black tone. Articles treated by this process are very resistant to saline atmospheres, but are not as resistant to wear as is galvanised or sherardised metal.—C. A. K.

Brass; Influence of cadmium on the properties of —. L. Guillet. Rev. Mét., 1919, 16, 105–115.

THREE series of copper-zinc alloys were studied, containing respectively 70% Cu with 0–4% Cd, 60% Cu with 0–1% Cd, and 55% Cu with 2–10% Cd. With the alloys containing 70% Cu the mechanical properties are not affected by cadmium up to 0.74%. An alloy containing 1.67% Cd possesses about the same breaking strain as when the cadmium content is lower, but the elongation is diminished and the metal becomes brittle. The breaking strain, elongation, and resilience of an alloy containing 1.92% Cd show low values, and the hardness (Brinell) increases until with 4.11% Cd the alloy has practically no mechanical strength, and the hardness attains a maximum. Micrographic examination shows clearly that brass containing up to 0.74% Cd possesses a normal structure (α solution); from 1.67% Cd upwards, increasing quantities of cadmium appear in the free state. Similar results were obtained with the other series of alloys, and it is concluded that up to 1% Cd has no deleterious effect on brass containing 60% or 70% Cu, and that a greater quantity than this influences first the resilience and afterwards the tensile strength. The coefficient of equivalence of cadmium in respect to these alloys is about 0.7. —C. A. K.

Monel metal; Rapid method for the analysis of —. P. Covitz. Chem. and Met. Eng., 1920, 22, 31–32.

THE accumulation of large volumes of filtrates, necessitating considerable evaporation, is avoided by using separate samples for the determination of the different constituent elements. Carbon is determined by direct combustion in a Fleming apparatus (Iron Age, Jan. 1, 1914). For the estimation of silica 1 gm. of Monel metal is dissolved in nitric acid and the solution evaporated to about 7 c.c., diluted to 50 c.c., and filtered. Dehydration of silica is not considered essential for most purposes. Copper is deposited by electrolysis from the filtrate made up to 150 c.c. and acidified with 5 c.c. of sulphuric acid (1:1), using a current of 1.5 amps. for 2 hours. A separate solution of 1 gm. of borings in nitric acid is used for the precipitation of iron and aluminium hydroxides, which are re-dissolved in hydrochloric acid and the iron re-precipitated by means of potassium hydroxide. Iron is estimated by reducing the solution of the precipitate in hydrochloric acid by means of stannous chloride and titrating with permanganate, using a "preventive solution" containing 160 grms. of manganous sulphate, 330 c.c. of syrupy phosphoric acid, and 320 c.c. of concentrated sulphuric acid in 1750 c.c. of water. Manganese is determined by the bismuthate method, and nickel by means of di-

methylglyoxime, care being taken to obtain the proper degree of alkalinity in the latter method.

—C. A. K.

Acid-resisting metals. C. Matignon. *Chim. et Ind.*, 1919, 2, 1283—1302.

THE introduction and development of ferrosilicons for acid-resisting plant are described and the properties and characteristics, especially as regards loss in various acids, of special ferrosilicon alloys are reviewed and tabulated (see Matignon, this J., 1918, 375 A; Tungay, this J., 1918, 87 r). Well-known examples are métillure, élianite, ironac, tantiron, and duriron. The influence of variation in the proportions of iron and silicon has been investigated. Some special applications to particular forms of plant and details in regard to their durability are given and methods of manufacture of the alloys, in so far as these are not secret processes, are described. Some investigations with ferroborens led to the conclusion that these are very inferior in acid-resisting qualities to ferrosilicons.

—W. J. W.

Copper-aluminium-iron bronze as an acid-resisting alloy. O. L. Kowalke. *Chem. and Met. Eng.*, 1920, 22, 37—38.

COPPER-ALUMINIUM-IRON bronzes possessing satisfactory mechanical properties were tested by the loss in weight when subjected, at atmospheric temperatures, to the attack of different acids of 10—50% concentration. A bronze having the composition 87.0% Cu, 9.8% Al, 3.14% “iron alloy” is particularly resistant to sulphuric, lactic, phosphoric, tartaric, and acetic acids, but is attacked by hydrochloric acid and ammonia, and at a rapid rate by nitric acid. By increasing the aluminium content of the alloy 1% (85.6% Cu, 10.8% Al, 3.57% “iron alloy”) the resistance to corrosion is increased materially, though nitric and hydrochloric acids still attack it too readily for commercial application.—C. A. K.

Copper-aluminium alloy; Experience with a 91:9 —. A. I. Krynitzky. *Chem. and Met. Eng.*, 1919, 21, 770—771.

THE preparation of a homogeneous alloy is difficult if more than 9% Al is present. Cast rods of an alloy containing 10% Al almost invariably contained blow-holes and showed segregation along the axis of the bar. Chill casting, at a temperature near to the melting-point of the alloy, is recommended, and the purity of the constituent metals is important. Rods of high aluminium content easily split longitudinally during rolling operations, the fracture often showing almost regular “teeth.” Successful working seems to limit the aluminium to 9%, and an alloy of this composition is readily machined at medium speed.—C. A. K.

Aluminium dross; Evaluation of —. F. K. Bezenberger. *J. Ind. Eng. Chem.*, 1920, 12, 78—79.

TO determine metallic aluminium in aluminium dross 1 grm. of the sample is treated with saturated bromine water, and a small quantity of bromine is added from time to time until the red colour of the bromine is permanent; the free bromine is then expelled by heating, the mixture filtered, the aluminium in the filtrate precipitated as hydroxide by ammonia, and the precipitate collected, ignited, and weighed. It is then treated with 10% sulphuric acid, which dissolves the cupric and ferric oxides present, a small portion of the alumina also passing into solution; after the copper has been deposited electrolytically the iron is reduced and titrated with permanganate solution. The amounts of cupric oxide and ferric oxide are deducted from

the weight of the ignited precipitate and the difference calculated as aluminium.—W. P. S.

Aluminium spontaneously oxidisable in the air. E. Kohn-Abrest. *Comptes rend.*, 1919, 169, 1393—1395.

WHEN aluminium is heated in a vacuum at 1100° C. (in boats of pure aluminium, in a soft iron tube) it slowly distils over, and if the heating is stopped after 16—20 hours it is found that the residual aluminium globules when exposed to the air at the ordinary temperature undergo spontaneous oxidation. The aluminium, which oxidises thus spontaneously, contains as impurities only 0.4% Fe and 0.5% Si.—W. G.

Zinc alloys; Study of cast — with special reference to their use as bearing metals. Gieren. *Z. Metallkunde*, 1919, 11, 14—22. *Chem. Zentr.*, 1919, 90, IV., 964—965.

THE applicability of alloys containing zinc as chief constituent as bearing metals is discussed. Schulz's statement that tin has a detrimental effect on all zinc alloys is not confirmed, but in agreement with Schulz iron was found to be detrimental, and the use of aluminium in place of tin to have a good effect. In the binary zinc-tin-alloys the presence of a eutectic can be detected even when only 0.5% Sn. is present. The melting point of zinc is lowered by 2% Mn to a eutectic point at 400° C. •With further addition of manganese other compounds having transformation points at 570° and 510° C. were formed. Between 0.5 and 1% Mn solid solutions are formed. In the ternary system Zn-Sn-Cu up to 4% Cu and 21% Sn, the constitutional properties of the binary systems Zn-Sn and Zn-Cu appear little changed. Experiments on the technological properties (corrosion, shrinkage, mechanical properties, structure, melting points, bearing properties) of some known and more or less complicated zinc alloys are also described in the original.

—T. H. Bu.

Arsenic; Estimation of — in tin and tin coatings. L. Vallery. *Comptes rend.*, 1919, 169, 1400—1402.

THE results obtained by using Marsh's method for the estimation of arsenic in tin are liable to serious error. If, however, the arsenic is first distilled off as arsenic chloride by the method of Hollard and Bertiaux (this J., 1900, 563), and the arsenic estimated colorimetrically in the distillate after reduction to colloidal arsenic by means of hypophosphorous acid the results are accurate to within 3% of the total at a concentration of 1 in 100,000.

—W. G.

Tungsten; Determination of — in ferro-tungsten. L. Löwy. *Z. angew. Chem.*, 1919, 32, 379—380.

FERROTUNGSTEN is completely decomposed when heated in a platinum or porcelain crucible with ammonium sulphate and concentrated sulphuric acid. The reaction takes place more slowly than in Wolter's process (this J., 1910, 157), but without attacking the porcelain or platinum. The sample is finely powdered in an agate mortar, and 0.5 grm. is heated in a porcelain crucible with 4 grms. of pure ammonium sulphate and 4 c.c. of pure sulphuric acid with frequent shaking until the evolution of sulphur dioxide has ceased, and the temperature is then raised but without igniting the mass, and the heating continued until black particles are no longer visible. After cooling, the mass is dissolved in water, the solution treated with 1 c.c. of concentrated nitric acid, heated to boiling, and, after the addition of 25 c.c. of strong hydrochloric acid (sp. gr. 1.19), boiled for a few minutes. When cold the liquid is filtered and the precipitate of pure tungstic acid washed with cold dilute hydro-

chloric acid (1:5). The filtrate is evaporated until fumes of sulphuric acid appear, cooled and diluted with cold water, and strong ammonia solution added drop by drop until the iron is precipitated. The filtrate is acidified with 10 c.c. of hydrochloric acid and evaporated to dryness, the residue treated with dilute hydrochloric acid (1:5), the solution boiled, cooled, and filtered from the small amount of tungstic acid thus separated, and the precipitate washed as before. For very accurate work a third precipitation may be made. The united precipitates are ignited in a platinum crucible until constant in weight, treated with hydrofluoric acid, and again ignited and weighed. To remove any iron still present the residue is fused with 2–3 grms. of anhydrous sodium carbonate, the mass extracted with hot water, the residue ignited, and the ferric oxide weighed.—C. A. M.

Tungsten metal; Manufacture of pure — C. H. Jones. Chem. and Met. Eng., 1920, 22, 9–16.

The process of manufacture of tungsten as carried on by The Faunsteel Products Co., U.S.A., is described. Hand-picked wolframite containing 73% WO₃ is finely ground in a Braun planetary disc crusher, mixed with 15% excess over the equivalent quantity of soda ash, and the mixture ground in a pebble mill so as to pass a screen with 100 meshes per linear inch. The charge is then roasted in a gas-heated reverberatory furnace at about 800° C., i.e., just sufficient to convert all manganese oxide into the dioxide. Magnesite or dolomite should be used as a lining for the furnace. The fritted mass is leached with water, and calcium chloride is added to the hot filtered solution of sodium tungstate. Calcium tungstate is precipitated and is treated with an excess of hydrochloric acid, and boiled to allow the formation of yellow tungstic acid. After repeated washing this product contains on the average 99.5% WO₃, and is the commercial acid known as Grade A. Further purification is effected by dissolving the tungstic acid in ammonia so as to obtain a 7% solution of ammonium paratungstate, which is filtered through a Sperry filter-press provided with filter paper between the filter-leaves. After evaporating to the consistency of mud the salt is thoroughly washed and treated with concentrated nitric acid. The resulting tungstic acid is calcined in silica crucibles to about 1000° C. The product is of a light green colour, due to a mixture of the yellow oxide (WO₃) and lower blue oxides of tungsten. It contains 99.95% WO₃, and any oxide containing more than 0.02% Fe₂O₃ is returned for further purification. More than 90% of the tungsten in the ore is recovered. A new type of furnace for the reduction of tungstic oxide consists of a silica tube, 4 in. diam. and 5 ft. long, wound with nichrome wire, and surrounded by an insulating casing. Dry pre-heated hydrogen is passed over the heated oxide in the furnace tube, and metallic tungsten is withdrawn as a gray powder, which is formed into bars by a hydraulic pressure of about 300 tons per sq. inch. The bars are sintered by placing them between contact points and subjecting them to a current of 2750 amps. at 220 volts, single phase, in an atmosphere of hydrogen, after which treatment they are drawn down to the required size and cut up by an abrasive cutting wheel.—C. A. K.

Metals and alloys; Fluidity of — D. Saito and K. Hayashi. Mem. Coll. Eng. Kyoto Imp. Univ., 1919, 2, 83–100.

For determining quantitatively the fluidity of metals a flat spiral test-piece is cast in a sand mould. The spiral has a cross-section 10 mm. by 7 mm. and is 5000 mm. long, the distance between the whorls being 25 mm., and the diameter of the outermost whorl 450 mm. The length of the test-piece measured when cold is taken as a measure of the fluidity. The temperature of the molten metal is measured

with a Pt-PtRh couple, and the test-piece is cast under a definite head of metal. The temperature of the mould is maintained between 35° and 40° C. Results are given for lead, zinc, tin, antimony, aluminium, copper, bronze, brass, grey and white iron, and crucible steel. For lead and zinc the fluidity is approximately the same; that of tin is higher. The fluidity of antimony is lower, and that of aluminium less still. The value of copper is about half that of lead. When less than 1.4% of tin is added to copper the fluidity diminishes; above that amount the fluidity increases. Phosphorus increases the fluidity of bronze. The fluidity of brass is about the same as that of bronze, and increases with the zinc content. The fluidity of white iron is approximately one-seventh that of grey iron, and is the lowest of the metals examined. Redcar iron, rich in phosphorus, has a greater fluidity than other grey cast irons examined.

—T. H. Bu.

Froth flotation: its commercial application and influence on modern concentration and smelting practice. W. Broadbridge. Inst. Min. Met., Jan. 22, 1920. [Advance copy.] 58 pages.

Froth flotation is now used to treat some 70 million tons of ore annually. All sulphide ores, including those containing native metals and non-metals, are broadly amenable to froth flotation treatment on a commercial scale. Oxides and carbonates of copper, tin oxide, and lead-silver oxides have also been brought within the scope of the process. Considerable advances have recently been made in differential flotation. Machines for mechanical agitation and sub-aeration are described, also for combining these processes, and for restricted or serial agitation. Flotation units are simple in construction, compact, and flexible, their capacity being large in proportion to their dimensions. Substantially improved recovery of mineral values is obtained by modifying the character of the water by addition of an emulsifying agent during the process of grinding. Pulp concentration is a vital consideration; the most effective water:solid ratio is between 3:1 and 4:1. The size of feed depends on the nature of the ore, and is determined experimentally. Oversize must be limited in quantity, and the quantity of material below 200-mesh size should not fall below a certain percentage. The flotation feed from all portions of the mill must be regular in order to maintain the proper proportions of reagents to feed. The grade of concentrates may be raised by re-treatment in the primary plant without further addition of reagents. This is, however, not possible in sub-aeration plants. The mineral froth is strong, persistent, and sometimes difficult to break down. Moisture in concentrates should be retained in excess of 5% to prevent dusting. Circulation of the plant-water results in a considerable saving of reagents. Ore reduction methods usually comprise two stages—primary crushing followed by secondary crushing. Multi-crushing is avoided. The finest slimes are readily amenable to treatment. Smelting difficulties in regard to flotation concentrates have been overcome. The development of the process has tended towards simplification of operations, flow sheets, and plant. There has been considerable development of labour-saving devices. The process has resulted in considerable saving of initial values, recoveries of over 90% being common where 70% was previously considered good work, and has had a far-reaching influence on the smelting of lead, zinc, and copper.—T. H. Bu.

Flotation; Use of naphthylamine and xylidine in — E. H. Robie. Eng. and Min. J., 1919, 108, 730–732. (See also this J., 1920, 28 A.)

Catene α -naphthylamine or "x-cake" forms a good flotation agent, acting both as a collector and a

frother, and in solution in xylidine excellent results are obtained. Solution takes place rapidly on heating, the usual proportions of the mixture being 60% of "x-cake," 40% of xylidine, although those proportions may be varied considerably to suit different conditions. When used on a bornite-chalcocopyrite ore the following results were obtained:—Feed, 4.5 Cu; tailing, 0.35%; concentrate, 10.78%; recovery, 95.53%. More rapid filtering follows as a higher grade concentrate is obtained, and a smaller amount of concentrate dewatered than when other flotation agents are used.—J. W. D.

Ores and metallurgical products; Treatment of complex —. W. Hommel. Metall u. Erz, 1919, 16, 501—511, 559—576.

THE separation of the individual metals from lead-zinc, copper-zinc, and lead-copper-zinc ores presents considerable difficulties. In some cases zinc blende may be mechanically separated from copper and iron pyrites, but magnetic and electrostatic separation generally give better results. Flotation processes are sometimes combined with roasting or magnetic separation. The dry processes comprise smelting the lead and copper with formation of a zinc-rich slag which is subsequently treated to yield zinc oxide; distillation of the ore to recover the zinc, with the production of lead-rich or copper-rich residues; application of direct blast to materials containing zinc and lead, a method which is only applicable to ores containing little precious metals. Owing to high metal loss in retorts, shaft furnaces are perhaps preferable for the recovery of the zinc by volatilisation. The addition of lime is valuable in the blast process. Wet processes may be grouped according to the solvent used. Sulphuric acid may be used either as concentrated or dilute acid. In the latter case it is usual to start with a low temperature roast and combine with electrolysis. A sulphatising roast or, in some cases, treatment with ferric sulphate may be used to produce zinc sulphate. Another method is the application of sulphurous acid and an oxidising agent. Zinc oxide may be used as an absorbent for sulphurous acid. The separation of zinc with hydrochloric acid or chlorine is advantageous for electrolytic purposes. Separation by means of alkalis and ammonia is not of much value. A solvent should be chosen according to the nature of the ores; the sulphurous acid method is probably the simplest. The best results are obtained by combining the various processes. It is recommended that the zinc should be lixiviated as far as possible before smelting, then treated in a shaft furnace and the slag subjected to blast for separating the remaining zinc. The commercial aspect of the various processes is discussed. Wet processes are not so costly as generally supposed.—T. H. Bu.

Rhodium and hydrogen. Gutbier and Maisch. See VII.

Lead as platinum substitute. Hütter. See XXIII.

Carbon dioxide and water in minerals. Ahmström. See XXIII.

PATENTS.

Ferro-alloys; Production of —. H. L. Sulman and W. B. Ballantine, London. Eng. Pat. 137,080. (Appls. 10,819, 2.7.18 and 19,318, 23.11.18.)

IN a thermo-reducing process for producing ferro-alloys containing chromium and tungsten for high-speed steels, compounds for example, oxides, of tungsten and chromium, containing these metals in chemical combination with each other are used, with or without compounds containing one of these metals and another metal required in the alloy, such as iron. The compounds of chromium and

tungsten are formed by precipitation from a solution of a salt of one of the metals by a salt or compound of the other metal.—J. W. D.

Puddling iron. A. E. White, London. From A. M. Byers Co., Pittsburgh, Pa., U.S.A. Eng. Pat. 136,704, 7.2.19. (Appl. 3066/19.)

A FURNACE and mechanical puddler comprises a tool supported on a carriage which draws the tool backwards and forwards, thereby agitating and "combing" the molten metal on horizontal, longitudinal parallel lines and producing a fibrous stratifying action therein. The furnace has a movable door at one end and longitudinal slots in the walls which are covered with a movable curtain or belt travelling with the supporting carriage. —J. W. D.

Iron; Process for treating —. W. J. Diederichs, Ithaca, N.Y. U.S. Pat. 1,325,626, 23.12.19. Appl., 10.4.17.

WHITE cast-iron castings are heated at about 1000° C. for a period of from 30 mins. to 4 hours, then withdrawn from the furnace and cooled gradually and uniformly.—J. W. D.

High-speed steels not containing tungsten. Stahlwerke R. Lindenberg, A.-G., Remscheid-Hasten. Ger. Pat. 312,311, 27.1.16. Addition to Ger. Pat. 309,175 (this J., 1919, 908 A).

THE steel contains C 0.5—0.8%, Mo 6—10%, Cr 3—6%, Mn 0.2—0.4%, Si 0.2—0.4%, and V 0.15—2%. The vanadium may be partly replaced by cobalt (0.5—3.5%). The addition of vanadium promotes deoxidation and the separation of small slag particles. It also refines the grain which results in greater toughness and better retention of cutting properties. The effect of cobalt is to widen the range of temperature at which the steel may be hardened.—T. H. Bu.

Steel; Process for producing all kinds of — in small basic-lined converters. P. Müller, Frankenberg. Ger. Pat. 314,153, 15.9.17.

WHERE the charge does not contain sufficient phosphorus and silicon for the blow, metallic calcium is either added to the iron or introduced with the blast, the heat of combustion of the calcium serving to raise the temperature of the charge. Owing to the absence of large quantities of silicon the addition of an excess of lime is unnecessary, the duration of the blow is diminished, the loss of iron is reduced, and basic slag containing the usual proportion of phosphorus is obtained. The calcium also combines with nitrogen and sulphur present in the steel.—J. H. L.

Iron and steel; Process for removing scale oxide from the surface of —. W. Fennie, Buhl, Minn, and W. W. Rhodes, Assignors to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,326,585, 30.12.19. Appl., 3.4.19.

THE metal is subjected to the action of an unsaturated solution of sodium bisulphate at 100°—200° F. (38°—93° C.). Normal salts are formed, and sodium bisulphate is added to the solution from time to time until it becomes saturated with salts, and no longer exerts a vigorous solvent action on the scale. The ratio of the normal salts to bisulphate is then decreased to restore the scale-dissolving activity of the solution.—J. W. D.

Blast-furnace air; Method of drying — and apparatus therefor. P. A. Mackay, London. Eng. Pat. 136,957, 17.2.19. (Appl. 3915/19.)

AIR from a blower passes into an acid chamber, containing acid (sulphuric or phosphoric) supplied under pressure by a circulatory system so as to keep its concentration approximately constant.

The air enters by means of a perforated crown submerged in the acid, and on leaving the acid container passes through a chamber containing coke to absorb any acid spray, and is then delivered to the blast furnace either direct or through a blast-furnace stove.—J. W. D.

Steel-making and like furnaces or mixers. Wellman, Seaver, and Heald, Ltd., London, and R. Gray, Redear, Eng. Pat., 137,200, 8.1.19. (Appl. 8890/19.)

A cooling device is used in combination with the port structure consisting of a pipe, or pipes, or passage, or passages, for the cooling medium surrounded by or embedded in an inward extension of the trough of the upper water-seal.—J. W. D.

Flotation apparatus. W. O. Borchardt, Austinville, Va., Assignor to New Jersey Zinc Co., New York. U.S. Pat. 1,326,174, 30.12.19. Appl., 24.1.17.

A gas is introduced into a series of shallow box-like compartments through porous bottoms comprising a supporting diaphragm and a layer of metallic spherules thereon. The ore pulp is subjected to a flotation treatment by causing it to flow longitudinally over the series of compartments, the tailings being deposited at the bend and the ore particles removed as an overflow froth.—J. W. D.

Ore-separating device. A. H. Jones, Tonopah, Nev., U.S. Pat. 1,326,453, 30.12.19. Appl., 11.4.16.

Is a flotation apparatus an upright conduit with means for admitting ore pulp at its lower end and a free annular overflow at its upper end is surrounded by an unobstructed annular perforated medium to receive the overflow. Inside the conduit are mechanical means for agitating the ore pulp and discharging it with an outward swirl upon the perforated medium, and means are also provided for forcing air through the perforated medium into the pulp.—J. W. D.

Copper ores; Process of leaching —. J. J. Nelson, Assignor to O. H. Westergaard and B. Mathews, Los Angeles, Cal. U.S. Pat. 1,326,463, 30.12.19. Appl., 26.3.18.

ORES containing copper sulphate are subjected to the action of a solution containing sodium bisulphate and sodium chloride, the gangue is filtered off, sodium chloride is added to the filtrate and the copper precipitated with finely divided iron.—J. W. D.

Copper; Process for hardening —. F. H. Ruth, Buffalo, N.Y. U.S. Pat. 1,326,693, 30.12.19. Appl., 6.3.18.

A QUANTITY of sulphur is added to molten copper, thoroughly mixed, and the mixture cast in the usual manner.—J. W. D.

Hardness and tenacity of metals and the ease of their working with cutting tools; Process for increasing the —. G. van Oordt, Assignor to Soc. Anon. des Usines Giulini, Basle, Switzerland. U.S. Pat. 1,326,775, 30.12.19. Appl., 30.4.19.

THE metal is heated to a temperature below the usual temperature for annealing.—J. W. D.

Antimony; Alloy to serve as substitute for — in hard lead and similar products. W. Zimmer, Giessen. Ger. Pat. 299,769, 9.1.16.

THE alloy claimed contains arsenic and tin, preferably in equal amounts. It forms alloys with the so-called white metals, lead, tin, antimony, etc., and also with copper, brass, bronze, and tombac. With lead it yields a good bearing metal, and with

suitable additions it may be used as a substitute for Britannia metal, and for the production of acid-resisting hard lead and bronze.—J. H. L.

Hard lead; Substitute for — for acid-resisting objects. W. Stockmeyer, Minden, and H. Hanemann, Charlottenburg, Ger. Pat. 301,721, 9.3.16.

A LEAD-SODIUM alloy containing 0.25% Na is as resistant towards water and sulphuric acid as a lead alloy containing antimony.—D. F. T.

Hard lead; Substitute for —. H. Hanemann, Charlottenburg, and W. Stockmeyer, Minden. Ger. Pat. 305,087, 27.2.15.

LEAD is alloyed with less than 4% of magnesium, and a small proportion of aluminium may be added. Alloys of lead with only 1% of magnesium possess greater hardness and tensile strength than ordinary hard lead containing 11% of antimony. They are not affected by air and water, and only slowly attacked by acids. Addition of a small quantity of aluminium increases the hardness still further.—J. H. L.

Metals; Process for working up alloys containing valuable —. Hirsch Kupfer- und Messingwerke A.-G., Halberstadt. Ger. Pat. 301,265, 18.2.17.

THE alloy is melted down in a known manner, and the resulting slag containing metals it is desired to recover is re-melted and reduced to obtain an alloy, which is afterwards subjected to electrolysis. The subsidiary metals in "black copper" can thus be quantitatively recovered and the copper itself obtained as electrolytic metal. The copper content of the electrolytic bath is preferably maintained above a certain value by addition of copper sulphate as required, and some of the liquor is withdrawn from the bath periodically or continuously to maintain the concentration of subsidiary metals and impurities below a certain limit. The liquor thus withdrawn is worked up for other metals, e.g., nickel. The metals insoluble in acid, e.g., tin, accumulate in the anode sludge.—J. H. L.

Alloys of low and high melting metals in all proportions; Production of —. E. Fernholz, Berlin-Tempelhof. Ger. Pat. 309,114, 23.3.18.

To avoid loss by volatilisation the metals are mixed, melted, cast, and cooled under high pressure until below the melting point of the more fusible component. It is thus possible to alloy mercury, potassium, sodium, cadmium, and zinc with iron, nickel, and manganese.—H. J. H.

Alloys of copper, zinc, and lead; Production of —. Vereinigte Hüttenwerke Burbach-Eich-Düdelingen A.-G., Düdelingen, Luxemburg. Ger. Pat. 314,315, 7.3.18.

COPPER and zinc mixtures in the usual proportions of the brasses (15 to 45% Zn with 85 to 55% Cu) are saturated or mixed with an excess of lead, viz., up to 60% reckoned on the finished alloy. The products resemble, in physical properties, a good phosphor bronze, but differ in the absence of tin and the low proportion of copper. Zinc in large proportion increases the mechanical strength and tends to keep the lead in solution. When the latter is in excess, a portion separates out, imparting plasticity to the alloy. Hardness is increased by the addition of a small proportion of aluminium or other metals.—H. J. H.

Alloys of lead with copper, zinc, and tin; Production of —. Vereinigte Hüttenwerke Burbach-Eich-Düdelingen A.-G., Düdelingen, Luxemburg. Ger. Pat. 314,316, 15.11.18.

THE molten metals are emulsified by heating the

mixture in an induction electric furnace. This effect is produced by the rapidly alternating current and is so pronounced that separation of emulsified constituents may not take place before solidification of the alloy.—H. J. H.

Lead coatings on metals; Production of —. Berlin-Burger Eisenwerk A.-G., Berlin. Ger. Pat. 314,789, 5.10.18.

A smooth durable deposit free from sponginess is obtained by the addition of a small quantity, e.g., 0.01%, of catechu to the plating bath.—D. F. T.

Aluminium; Method for welding or melting —. Chem. Fabr. Griesheim-Elektron, Frankfurt. Ger. Pat. 315,231, 2.5.17.

In order to regulate the melting point of the flux a mixture of various halides of the alkali metals is used; for pure aluminium, a mixture of 4 parts of potassium chloride with 3 of sodium chloride, 1 of lithium chloride, 1 of potassium bromide, and 1 of sodium fluoride, with a melting point near 600° C., is very useful.—D. F. T.

Iron and steel turnings, scrap, and the like; Melting of —. R. A. Hadfield, London. U.S. Pat. 1,326,861, 30.12.19. Appl., 16.9.18.

XI.—ELECTRO-CHEMISTRY.

Electrolytic decomposition of organic acids; Apparatus for — at low temperature and with small volumes of liquid. *Electrolytic decomposition of the alkali salts of citraconic acid.* F. Henrich and W. Schenk. Ber., 1919, 52, 2120—2125.

THE apparatus consists of a small inverted flask, the bottom of which has been removed and the neck of which is provided with a cork holding a small inverted tube. The latter serves the dual function of diminishing the size of the apparatus to the required extent and of allowing efficient cooling by the introduction of a stream of cold water into the tube. As anode, a stout platinum wire, or, preferably, platinum gauze, is placed in close proximity to the tube. The cathode consists of a piece of nickel gauze. The apparatus is easily maintained at 25°—40° C. A gas holder of the type described previously by Henrich (Ber., 1908, 41, 4199) is used for collection of the anode gases, and arrangements are also made for the analysis of these gases at any

desired moment. Electrolysis of concentrated, faintly alkaline solutions of potassium citraconate yields a mixture of oxygen, carbon dioxide, and allylene at the anode. The yield of the latter is favoured by low temperature, high concentration of solution, and high current; it is also found to depend on the particular alkali salt used, increasing from lithium through sodium and potassium to rubidium and then declining when the caesium salt is employed. (See also J. Chem. Soc., 1920, i., 142).—H. W.

Electrometric titrations. Pinkhof. See XXIII.

Hydrogen-ion concentration. Pinkhof. See XXIII.

PATENTS.

Chemical reactions between liquids, gases, or liquids and gases; Method for the electrical treatment of the reagents for —. F. H. A. Wielgolaski, Christiania. Ger. Pat. 304,479, 7.10.15.

THE reaction mixture is submitted to an alternating electric discharge of high frequency between massive porous or perforated electrodes, the reacting or activated substances being in direct contact with the electrode surfaces without the interposition of any other dielectric. The reaction mass may simultaneously be exposed to activating radiation such as Röntgen rays or ultraviolet light. If liquids are being treated, suitable contact substances may also be introduced. The hydrogenation of blubber oil is given as an example.—D. F. T.

Magnetisable cores; Process for the production of —. E. F. Huth, G.m.b.H., and S. Loewe, Berlin. Ger. Pat. 305,048, 30.11.16.

THE magnetisable material (iron, cobalt, nickel, or Heusler's alloy etc.) is atomised and incorporated with insulating material, preferably in the form of alternating layers of the two materials. Thus, for example, a very thin layer of iron may be sprayed upon paper which is then lacquered, a second layer of iron is then sprayed thereon, and so on, until a sheet of the desired thickness is obtained.

—J. S. G. T.

High-tension electrodes for use in the electrical purification of gases. Siemens-Schuckertwerke G.m.b.H., Siemensstadt. Ger. Pat. 314,775, 11.10.18.

A NUMBER of high-tension electrodes are arranged in juxtaposition in the precipitation chamber, and are connected at their lower ends by a transverse conductor serving to bind them together. The floor of the precipitation chamber is made conducting and earthed. An electric field is established between the electrodes and the floor, thereby diminishing the dead space in the chamber.

XII.—FATS; OILS; WAXES.

Momordica seeds; Fat of —. C. E. Corfield and E. Card. Pharm. J., 1920, 101, 43—44.

The seeds of *Momordica cochinchinensis*, a cucurbitaceous plant indigenous to Bengal, the Philippine Islands, etc., have been found to contain on the average 63.3% of kernels. On extraction with petroleum spirit the kernels yielded 47.06% of a greenish fat. A good yield was also obtained by coarsely powdering the kernels and expressing them at about 40° C. in a press surrounded by a steam coil. A sample thus expressed had m. pt. 28°—32° C.; refr. index (40° C.), 1.495; acid value, 1.9; saponif. value, 185.2; iodine value, 23.1. *Fatty acids:* M. pt. 46°—51° C.; solidif. pt., 44°—42° C.; neutralisation value, 188.3; and iodine value about 40. The fat consisted chiefly of glycerides of fatty acids, and no wax alcohols were present. When exposed to the atmosphere the fat gradually became pale yellow and ultimately granular in appearance. When slowly heated to 200°—240° C. the fat was converted into a greenish-brown liquid, which remained liquid and of about the consistence of castor oil on cooling. It then behaved as a semi-drying oil, forming a transparent skin after two days' exposure in a thin layer. In this condition it could probably be used in admixture with drying oils for varnishes and paints.—C. A. M.

Catalytic actions at solid surfaces. II. Transference of hydrogen from saturated to unsaturated organic compounds in the liquid state in presence of metallic nickel. E. F. Armstrong and T. P. Hilditch. Proc. Roy. Soc., 1919, 96 A., 322—329.

EVIDENCE is adduced in support of the view that the catalytic action of metallic catalysts, during the hydrogenation process, is reversible. It is shown that certain saturated organic compounds in the liquid state in the presence of nickel and an unsaturated organic compound at 180°—230° C. undergo dehydrogenation, passing on hydrogen to the unsaturated compound. This work affords an explanation of the results obtained by Moore (this J., 1919, 320 T) during the hydrogenation of unsaturated glycerides. It is suggested that, in the hydrogenation of ethyl oleate, a portion of the freshly-produced ethyl stearate in contact with the nickel undergoes dehydrogenation, the hydrogen liberated being transferred to more ethyl oleate, and the "dehydrogenated ethyl stearate" produced being the ethyl $\Delta^{11,12}$ -oleate isolated by Moore (*loc. cit.*). See further J. Chem. Soc., 1920, ii., 102.)—W. G.

Corn [maize]; Effect of mould on the oil in —. F. Rabak. J. Ind. Eng. Chem., 1920, 12, 46—47.

To determine the effect of mould growth on the oil in maize, a quantity of the latter was placed in a stone jar and inoculated with *Penicillium*; portions were removed at intervals for a period of 90 days and the oil extracted and examined. At the end of 90 days the maize was a dirty gray solid mass which had a strong offensive odour. The acid value, acetyl value, and unsaponifiable matter showed increases, and the iodine value decreased. There was a steady decrease (from 5.58 to 2.02%) in the amount of oil obtained from the maize, indicating that the oil was consumed by the mould.—W. P. S.

Soya bean leaves; Ether extract of —. E. M. Nelson. J. Ind. Eng. Chem., 1920, 12, 49—50.

SOYA BEAN leaves do not form an available source of

oil for paint manufacture, since they yield only 3—6% of ether extract, and the most highly unsaturated compounds in the extract are not oils, but probably cyclic alcohols (phytosterol and stigmasterol) and carotin, which do not form a hard film on drying. W. P. S.

Sulphonated oils [;Determination of moisture in —]. C. F. Barber. J. Soc. Leather Trades Chem., 1919, 3, 206—208.

A REPORT on the work of a committee of the Society of Leather Trades Chemists on the determination of moisture. Heating in an open dish with a free flame gave fair results in the hands of one member, whilst others found long heating at 100° C. unsatisfactory owing to slow decomposition of the oil. Distillation with toluene, commercial petrol, and water-saturated xylene gave identical results; petrol has the advantage of complete insolubility in water. Most workers found medicinal petroleum unsatisfactory on account of too high boiling point. —F. C. T.

Ghedda or East Indian wax. II. Its acids. A. Lipp and E. Kovács. J. prakt. Chem., 1919, 99, 243—255. (Compare this J., 1912, 731.)

MARGARIC acid, a previously unknown hydroxymargaric acid, m. pt. 58° C., and an acid sparingly soluble in ether (see following abstract), with small amounts of formic and butyric acids, were obtained from the wax. (See further J. Chem. Soc., 1920, i., 110.)—J. K.

Ghedda or East Indian wax. III. Hydrocarbons and acids. A. Lipp and E. Casimir. J. prakt. Chem., 1919, 99, 256—258.

THE wax contains approximately 48% of ceryl alcohol, 7% of hydrocarbons (5% of heptacosane, 2% of hentriacontane, with traces of a hydrocarbon of low m. pt.), 24—25% of hydroxymargaric acid, m. pt. 55°—56° C. (see preceding abstract), 1.5—2% of hydroxymargaric acid, m. pt. 71°—72° C. (hitherto unknown), 9—10% of margaric acid, 8—9% of palmitic acid, 2% of "ghedda" acid, and 1% of cerotic acid, with traces of formic, acetic, and butyric acids and tarry matter. Cerotic and ghedda acids are present mainly in the free condition, the others in the form of their ceryl esters. "Ghedda" acid, m. pt. 94.5°—95° C., is given the provisional formula $C_{44}H_{88}O_2$. Its separation depends on its sparing solubility in ether and that of its potassium salt in alcohol. (See further J. Chem. Soc., 1920, i., 111.)—J. K.

Melissyl alcohol and melissic acid. A. Heiduschka and M. Garais. J. prakt. Chem., 1919, 99, 293—311.

CARNAUBA melissyl alcohol and beeswax melissyl alcohol have been characterised by a series of derivatives and shown to have the formulae $C_{30}H_{60}OH$ and $C_{31}H_{62}OH$ respectively. Melissic acid from carnauba melissyl alcohol had m. pt. 90° C. (lead salt, m. pt. 118° C.), whilst that from beeswax had m. pt. 88.5° C. (lead salt, m. pt. 115° C.), and was identical with the product of hydrolysis of carnauba melissyl cyanide. (See further J. Chem. Soc., 1920, i., 131.)—J. K.

Oils; Extraction of — by volatile solvents. A. W. MacIlwaine and G. F. Holdcroft, North Ferriby, Yorks. Eng. Pat. 136,870, 9.12.18. (Appl. 20,425, 18.)

OIL-YIELDING material, reduced to a mealy condition, is extracted with benzoline (petroleum spirit)

or other solvent in an extractor, washed, the oil-bearing solvent drained off, and the meal transferred to a closed hopper, at the base of which is arranged a feed apparatus comprising a horizontal sliding box. By oscillatory motion the lower opening of the latter is brought directly above a hydraulic press, into which its contents are discharged. The sliding box then recedes to its former position beneath the extractor, whilst a sliding plate, one portion of which is solid and another portion has an opening corresponding with the plunger, closes the upper end of the press. The plunger then rises and compresses the mass, the oil-charged solvent escaping through the sides of the press and being drained away and collected. The sliding plate is then moved to the position in which it allows passage of the plunger, which is then further raised to place the pressed meal on the horizontal edge of a hopper and directly in the path of the sliding box previously referred to. The sliding box, in its passage forward to recharge the press, the plunger of which is then lowered, discharges the pressed meal to the bottom of a hopper leading to a breaking apparatus, *e.g.*, toothed rolls, from which it passes to a perforated steam-jacketed cylinder fitted internally with a conveyor and agitator to recover the solvent, and thence to a similar cylinder acting as a dryer, being finally discharged past a loaded flap, the material passing entirely through the system without exposure to air. A container, intermediate between the extractor and press, may be employed.—A. de W.

Turkey-red oil; Production of a substitute for —.
Chem. Fabr. Flörsheim H. Noerdlinger, Flörsheim. Ger. Pat. 310,541, 19.12.15.

The so-called "liquid resin," obtained as a waste product in the production of cellulose from pine wood, is distilled under reduced pressure. The distillate contains an oil resembling a fatty oil and a solid acid resembling abietic acid. After the separation of any crystallisable constituents, the distillate is sulphonated with sulphuric acid. The resulting sulphonic acids, which are almost completely soluble in water, give solutions which can be rendered almost neutral, but complete neutralisation gives rise to semi-solid or gelatinous soaps. The solutions form convenient media for the emulsification of all kinds of oils, fats, and organic liquids generally, with water; they can also be applied in the textile industry for mordanting, dressing, and other purposes and to the production of emulsified lubricants and of disinfectants.—D. F. T.

Nickel catalysts; Revivifying exhausted — which have been used in hydrogenation of fats. H. Schlinek und Co. A.-G., Hamburg. Ger. Pat. 314,685, 22.1.16.

The spent catalyst, without previous separation of the last traces of fat, is boiled with a dilute alkaline or alcoholic solution, and is then washed completely free from alkali sulphate. The residue is heated in a current of hydrogen so that the temperature increases at a rate not greater than 150° C. in an hour, and reaches the maximum of 650° C. in not less than 4–5 hours. Under these conditions the nickel particles are not coated with carbon.—L. A. C.

Detergent containing active oxygen; Preparation of a —. Kraemer and Flammer, and L. C. Kelber, Heilbronn. Ger. Pat. 314,590, 1.4.15.

The addition of lysalbinic acid, or protalbinic acid (decomposition products of proteins), or their salts, to a mixture of soap, sodium carbonate, and an oxidising agent such as sodium perborate increases the bleaching action of a solution of the same. For example, a 1% solution of the mixture on heating contains about 50% of the original

active oxygen at 90° C., whereas in the absence of protalbinic acid or lysalbinic acid no active oxygen is present under the same conditions.—L. A. C.

Lead pigment; Method for making —. J. E. Seeley, Los Angeles, Cal. A. R. Seeley, administratrix. U.S. Pat. 1,325,960, 23.12.19. Appl., 5.2.17. Renewed 6.10.19.

A FINE stream of melted lead is poured into water to obtain the metal in a finely divided condition with a coating of oxide, such divided lead being then subjected to the action of ozonised air, water, and carbon dioxide.—A. de W.

Phenol formaldehyde condensation products. F. J. Robinson, Cowley, Middlesex, and Damard Lacquer Co., Ltd., London. Eng. Pat. 136,298, 20.12.18. (Appl. 21,352/18.)

A PHENOL-FORMALDEHYDE condensation product which is flexible while hot, and can be bent or moulded by heating it to about 120° C., is produced by heating cresol 750 parts, formaldehyde (40%), 675 parts, ammonia (sp. gr. 0.880) 90 parts, and castor oil 50 to 80 parts. The oil may be added at first, or after partial condensation has taken place and the aqueous layer that separates has been removed. The final hardening is carried out in the usual manner by heating in an inert atmosphere. The castor oil may be replaced by camphor, linseed, rape, cottonseed, or other oils.

—L. L. L.

Varnishes or dopes; Manufacture of —. Titanine, Ltd., and P. E. Bowles, Radlett. Eng. Pat. 136,927, 7.1.19. (Appl. 467/19.)

A CELLULOSE ester varnish, to which has been added boric acid or a borate sufficient to produce at least 0.2% of free boric acid, can be stored for several months in a galvanised iron drum with only a negligible drop in viscosity.—A. de W.

Resinous condensation product and process of making same. H. V. Dunham, Mount Vernon, N.Y. U.S. Pat. 1,324,649, 9.12.19. Appl., 4.4.19.

RESINOUS condensation products are obtained by passing a mixture of vaporised di-enes over a heated contact mass, the temperature of the latter being substantially above the melting point of the resinous product.—L. L. L.

[Artificial] resin. M. Darrin, Wilksburg, Pa., Assignor to The Koppers Co., Pittsburgh, Pa. U.S. Pat. 1,326,579, 30.12.19. Appl., 27.7.18.

A NEUTRAL resin is prepared by polymerising by heat compounds which occur in crude solvent naphtha; the clear reddish product has m. pt. above 180° C., and contains less than 0.03 ash and less than 0.06 moisture and volatile matter.—L. A. C.

Resin solutions resembling varnish or gum; Production of — from tar. C. Molhardt, Mödling, Austria. Ger. Pat. 305,065, 19.4.17.

CRUDE tar is diluted with the neutral oils which are removable from it by distillation with steam at 150° C.; after removal of any deposited solids the filtrate is freed from all volatile oils, phenol, naphthalene, and similar substances by distillation with steam at a temperature not exceeding 150° C. The residue from the first distillation may alternatively be treated with drying oils or with suitable oxidising agents and be used as a substitute for drying oils; the distillate contains all the constituents which in ordinary distillation would be collected between 270° and 350° C.; on account of the absence of decomposition, however, the liquid may be applied to purposes for which the use of more volatile fractions is customary.—D. F. T.

Linseed oil substitute. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 305,515, 21.3.17.

CLAIM is made to linseed oil substitutes for varnishes etc., consisting of derivatives of indene in which the double linkage of the cyclopentadiene ring is present: e.g., the oily products obtained from indene or tar distillation fractions containing indene, by introduction of alkyl or aralkyl groups, and in particular monobenzylindene (m. pt. 33°–34° C.), a mixture of mono- and dibenzylindene, xylylated indene, and indene oxalic ester.—J. H. L.

Leather substitute. Eng. Pat. 135,921. See XV.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin solutions; Structure of —. F. C. Thompson, J. Soc. Leather Trades' Chem., 1919, 3, 209–216.

GELATIN solution of from 0.2 to 0.6 concentration are elastic solids, though apparently quite liquid and mobile. They are composed of a tenuous network of solid gelatin with a continuous phase of water in the interstices. The apparent viscosity of such solutions as found by direct methods is considerable, and is due to rupture of the network. This viscosity is to be distinguished from that of the interstitial water, since diffusing ions and molecules can move in the solutions (and even in jellies) with velocities equal to those in pure water, and are unaffected by the apparent viscosity of the solution. If sugar or a similar substance is added to the water from which the jelly or solution is made, then the true viscosity of the interstitial liquid is raised and the motion of ions etc. is retarded, although the apparent viscosity is little affected. Moreover, gelatin solutions of the concentrations specified will resist indefinitely a small but definite shear, whilst simply viscous liquids such as oils or sugar solutions yield continuously. Double refraction (implying structure) is also shown by gelatin solutions under static stress.—F. C. T.

Sulphonated oils. Barber. See XII.

PATENTS.

Hides or skins; Tanning and liming of —. L. and G. Dufour, Genoa, Italy. Eng. Pat. 125,362, 1.3.19. (Appl. 5124/19.) Int. Conv., 6.4.18.

DELIMING is effected by means of sulphurous acid at 30°–35° C., and the goods are then tanned—preferably at 30°–35° C.—in liquors into which sulphur dioxide is passed to saturation from time to time. To economise tanning liquor some of the excess liquor in the tanning vats may be added to the deliming liquors. It is claimed that a very fine grain is produced, and that the resulting leather is of very good colour.—E. W. L.

Hides; Tanning animal —. W. Clark, London. From Chem. Fabr. Worms A.-G., Frankfurt, Germany. Eng. Pat. 136,193, 8.5.18. (Appl. 7720/18.)

PICKLED skins, freed from hair and prepared by any known method, are treated with a tanning liquor, prepared by dissolving sodium formate (6 kilos.) in water (20 litres), adding the solution to a neutral solution of ferric chloride (5 kilos.) in water (20 litres), and then allowing to stand for some time and diluting with an equal volume of water. Alternatively ferric hydroxide, prepared by the action of ammonia or other alkali on ferric chloride, is dissolved in the calculated quantity of formic acid, and solid iron formate is separated by cooling to about 0° C. The formate is dissolved in water to give a solution of 3° B. (sp. gr. 1.021). In 100 litres of this liquor 100 kilos. of pickled skins are tanned for 4–8 hours, drained for 24 hours, "cleaned" with 1% solution of borax for ½ hr., re-tanned with

sulphite-cellulose extract diluted with three times its volume of water (10° – 12° B., sp. gr. 1.074–1.091), drained for 24 hrs., and dressed like bark-tanned leather.—E. W. L.

Leather; Process of treating — A. J. Hawkins, Montreal, Canada. U.S. Pat. 1,326,261, 30.12.19. Appl., 12.11.18.

LEATHER is covered with a thin coating of oil at about 150° F. (66° C.) and cooled to 80° F. (27° C.) in 12 hrs.; the process is then repeated a number of times.—L. A. C.

Leather compositions [substitutes]. W. Drury, London. Eng. Pat. 135,921, 2.12.18. (Appl. 19,902/18.)

RAW rubber is masticated between hot rollers and an intimate mixture of very finely ground leather (leather flour), filling material, and sulphur is added to it, together with a small amount of factis or similar fatty material. Mastication is continued until the mass is homogeneous, and the temperature of the rolls is then raised to about 240° F. (116° C.) for about 15 mins., in order to effect partial vulcanisation. The mass is passed through a refining mill and formed into thin sheets between calender rolls. Sheet of the requisite thickness is obtained by superposing layers of the thin sheet in alternate directions, and vulcanisation is then completed.

—E. W. L.

Leather substitute; Composition of matter for use as a — J. W. Matthaei, Ingram, Pa., Assignor to Armstrong Cork Co., Pittsburgh, Pa. U.S. Pat. 1,326,681, 30.12.19. Appl., 3.12.18.

A LEATHER substitute contains an excess by weight of rubber, an excess by bulk of cork particles, fibrous materials, reclaimed rubber, sulphur, and glue.

—L. A. C.

Varnished (patent) leather; Method of treating — H. Schulz. Assignor to C. Heyl, Worms, Germany. U.S. Pat. 1,325,415, 16.12.19. Appl., 12.12.16.

VARNISHED leather is subjected to the action of light rich in ultra-violet rays in a closed chamber, through which a current of air, previously heated to above 40° R. (50° C.), is continuously forced.

—E. W. L.

XVI.—SOILS; FERTILISERS.

Soils; Effect of variation in moisture content on the water-extractable matter of — J. C. Martin and A. W. Christie. J. Agric. Res., 1919, 18, 139–143.

Pot experiments were made with two soils, a silty clay loam and a sandy loam, under varying conditions of moisture content from air-dry to just above the optimum content. Analyses were made at intervals during six months. The concentration of the soil solution and the amounts of nitrate and potash were found to tend to be slightly less in the samples near the air-dry condition. The concentration was more markedly depressed in the sandy loam when near the saturation point, the nitrates disappearing entirely. It is concluded that the examination of soils by the water extraction method is not invalidated by variations in moisture content, provided the saturation point is not reached.

—J. H. J.

Sulphur in soils; Effect of oxidation of — on the solubility of rock phosphate and on nitrification. O. M. Shedd. J. Agric. Res., 1919, 18, 329–345.

COMPOST experiments were carried out with various soils mixed with rock phosphate, sulphur, and stable manure. Analyses showed that little solution of

phosphate took place until the compost was inoculated with a small proportion of soil rich in sulphate-forming bacteria. After 2 years' time the amount of total phosphorus rendered soluble in water was 17% and in ammonium citrate solution 84%. This was accompanied by a rise in acidity and formation of sulphate. During the same period 20% of the total nitrogen in the compost was converted into nitrate. The conditions most favourable to the oxidation of the sulphur were found to be warmth, aeration and average moisture content.

—J. H. J.

Carbonates of calcium and magnesium; Natural — in relation to the chemical composition, bacterial contents, and crop-producing power of two very acid soils. S. D. Conner and H. A. Noyes. J. Agric. Res., 1919, 18, 119–125.

IN pot experiments on two very acid soils, a yellow clay and a black sand, wheat, clover and beet were grown with applications of calcite, dolomite, and magnesite at the rates of 4000 and 12,000 parts per million. Although calcium and magnesium compounds were present in both soils, yet the further applications made caused a good crop increase in every case except that of the larger quantity of magnesite on the black sand soil when no growth occurred. Beets tended to be benefited more by magnesium carbonate, while wheat and clover were benefited more by calcium carbonate. The ratios of calcium oxide to magnesium oxide which permitted growth varied from 2:1 to 1:5 on the yellow clay soil and from 3:1 to 1:4 on the black sand soil. The magnesium applications increased the salinity of the soil solution more than the calcium applications, and nitrification also was greater with magnesium. The numbers of bacteria were increased more by calcium in the black sand soil and by magnesium in the yellow clay soil.—J. H. J.

Calcium cyanamide and dicyanodiamide as vegetation factors. E. Linter. Diss., Königsberg, 1917. Bied. Zentr., 1919, 48, 414–417.

PREVIOUS work has shown that dicyanodiamide, which often occurs in crude calcium cyanamide or may be formed by decomposition in the soil, is unfitted for the nutrition of plants and is to be regarded as a poison, its presence resulting in the diminution of field crops and usually in the formation of characteristic white-tipped leaves. In the experiments described, mixtures of dicyanodiamide solution with soils of different characters were kept for some days at 30° C. in presence of carbon dioxide, the mixtures being shaken for seven hours each day. With sand or clay no decomposition of the dicyanodiamide occurred, so that the deleterious effect of the compound persisted until the latter was washed out, this naturally requiring longer in heavy, impervious soils than in lighter ones. In applying calcium cyanamide it is, therefore, advisable to avoid any procedure which would lead to increased formation of dicyanodiamide, for instance, spreading on freshly ploughed land in the autumn or top-dressing in the summer. On the other hand, humic soils are capable of absorbing dicyanodiamide so strongly that the poisonous action gradually disappears, the dicyanodiamide being apparently decomposed, possibly with formation of beneficial nitrogen compounds.—T. H. P.

Waste liquors from the potash industry; Action of — on soils and plants. O. Nolte. Landw. Jahrb., 1918, 51, 563. Bied. Zentr., 1919, 48, 417–426.

THE residual liquors left after crystallisation of crude potassium salts contain, in grms. per litre: $MgCl_2$, 390; $MgSO_4$, 35; $CaCl_2$, 10; $NaCl$, 9; and $MgBr_2$, 1. These liquors effect, especially with rich soils, at first an increase in the crop, but later often

a diminution; this diminution is more marked when the soil is poor in nutrient material and it may be mitigated, but not completely counterbalanced, by copious manuring. The amount of nutrient material taken up from the soil appears, indeed, to be slightly increased rather than diminished by the presence of these liquors. The ash-content of the crop is increased, more magnesia being taken up, although 1% of magnesia, calculated on the dry matter, is never reached; on the other hand, the amount of soda extracted from the soil is diminished in presence of the liquor. In the soil profound changes are produced by the liquor, interchange of bases and liberation of fertilising substances taking place. The amount of nitrogen washed out from the soil appears to be diminished and the same is the case with the phosphoric acid. Increased loss of potash does not occur, except with soils very rich in this constituent; with poor soils, indeed, accumulation of potash is observed. Washing-out of the soda is prevented. The most serious effect produced is the marked de-liming of the soil. The behaviour of the crude potash salts exhibits certain similarities to that of the residual liquor; the chemical composition of the crop remains, however, normal, the absorption of fertilising materials being undisturbed.—T. H. P.

Human urine and desaccharified sulphite-cellulose waste liquors: Plant fertilisation by —. T. Bokorny. Mitt. Deuts. Landw.-Ges., 1919, [1]. Bied. Zentr., 1919, 48, 426—430.

FURTHER experiments confirm the applicability of human urine and of sulphite-cellulose waste liquors as fertilisers (see this J., 1918, 436 A and 1919, 218 A). Laboratory tests with wheat, rye, and beans showed that urine is injurious when diluted to the extent 1:50, but harmless if the dilution is 1:100 or 1:200. The sulphite liquors produced no ill effects when diluted 50 times, or, if previously freed from sugar, when diluted 10 times.

—T. H. P.

Hydrogen cyanide; Effect of — on plants. C. Wehmer. Biochem.-Zeits., 1918, 92, 364—376.

GREEN cress is killed within 10 days by 0.24 mgrm. of hydrogen cyanide per litre of air. In order to achieve the same result with seeds placed in water 71.3 mgrms. of hydrogen cyanide per litre of air is required, although 2.375 mgrms. of the poison per litre of air greatly impairs their germination and development. Green leaves submerged in water are also killed by very dilute solutions of hydrocyanic acid.—S. S. Z.

Nitrates; Do seedlings reduce —? J. Davidson. J. Biol. Chem., 1919, 37, 143—148.

SEEDLINGS do not reduce nitrates of external media as part of their metabolic processes.

—J. C. D.

PATENT.

Seeds: Electrification of — and apparatus therefor. J. J. H. Sturmev, Coventry, and J. Hewett, Hampton, Middlesex. Eng. Pat. 136,920, 2.1.19. (Appl. 84/19.)

SEED after undergoing the Wolfryn electrification process (Eng. Pat. 22,151/13; this J., 1914, 1067) is submitted to a preliminary removal of excess moisture in a centrifugal machine, and is then lifted to the top of a tower furnished with a series of inclined planes set alternately towards each other. While the seed is falling from plane to plane it meets an upward current of air which may be heated and dried if necessary. Instead of a tower a rotating drum may be used in which vanes fixed to the periphery lift the seed and a current of air is drawn through, or the drum may be stationary and the vanes fixed to a revolving shaft.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Sugar cane juice; Colour changes of — and the nature of cane tannin. F. W. Zerbau. J. Ind. Eng. Chem., 1919, 11, 1031—1036. (See also this J., 1918, 778 A.)

It has previously been shown that oxydases and iron are concerned in the colour changes of cane juice. The third factor known to be involved is a water-soluble polyphenol which gives a green coloration with ferric salts. This has now been isolated from the juice and is found to be a true tannin derived, like the oak tannins, from catechol. It is precipitated from cane juice by normal lead acetate, but not by lead nitrate. It is soluble in water, alcohol, acetone, and ethyl acetate, and practically insoluble in ether, benzene, and chloroform. Catechol itself is not present in cane juice.

—J. H. L.

Molasses; Water content of true final cane —. H. C. Prinsen Geerligs. Int. Sugar J., 1920, 22, 34—40.

VAN DER LINDEN (Archief, 1919, 1511) has continued the experiments previously commenced by the author (this J., 1918, 385 A) in order to establish the optimum water content for factory conditions. It was concluded from the results obtained that the optimum water content is about 15—16%, corresponding to a ratio of sucrose to water of 100:161—200, a value in reasonably close agreement with that previously found by the author. It was also apparent that the constitution of some molasses hinders their exhaustion to the same extent as others which are more normal in composition, a low ratio between reducing sugars and ash (1.9—3.2), for example, coinciding with a high purity (39°—43°). In practice boiling and crystallisation are frequently not prolonged sufficiently to permit the maximum yield possible of sucrose to deposit upon the crystals already formed, the result being that after centrifuging when subsequently the temperature of the molasses falls a further deposition of sucrose in the form of very fine grain occurs (cf. also Kalshoven, this J., 1920, 126 A). In general, the procedure that should be followed in the factory in order to obtain molasses from which no further sucrose can be obtained on evaporation is to concentrate the final massecuite having an apparent purity of about 60° until its water content is 15—16%. After discharging from the vacuum pan into crystallisers, the product is maintained for at least 3—4 days in slow and constant motion, while cooling very gradually, finally centrifuging at a temperature of about 45° C. As a check on this operation it is advisable that the final molasses should be examined refractometrically directly after separation and also a week later, following the procedure recently described by Kalshoven (*loc. cit.*).—J. P. O.

Lactose; Catalytic hydrogenation of —. J. B. Senderens. Comptes rend., 1920, 170, 47—50.

IN a repetition of Ipatieff's work (this J., 1913, 107) it is shown that in the catalytic hydrogenation of lactose in aqueous alcoholic solution by means of nickel and nickel oxide, if a weak catalyst is used the action stops when the aldehyde group is reduced to a CH_2OH group, and the product lactositol, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$, m. pt., 78° C.; $[\alpha]_D +12.2^\circ$ in aqueous solution, has been isolated. On hydrolysis with dilute sulphuric acid it yields sorbitol and galactose. If a more active form of catalyst is used the hydrogenation proceeds further and the molecule is split up, the products being sorbitol and dulcitol.

XVIII.—FERMENTATION INDUSTRIES.

Acid formation by moulds and yeasts. F. Boas and H. Leberle. *Biochem. Zeits.*, 1918, 92, 170—188.

THE formation of acid by *Mycoderma*, *Oidium*, and *Aspergillus niger* in media containing various carbohydrates and nitrogenous ingredients has been studied. Most of the acid is formed from the carbohydrates. When, however, an ammonium salt of a strong acid forms the source of nitrogen the liberated acid suppresses the formation of acid from the carbohydrates. The ammonia produced in the fermentation process from the various nitrogenous compounds by means of enzymic action greatly influences the acid formation. The extent of this influence depends on the character of the organism and the nature of the carbohydrate employed.

—S. S. Z.

Glycerol formation in alcoholic fermentation; Natural and artificial —. C. Neuberg and E. Reinfurth. *Biochem. Zeits.*, 1918, 92, 234—267.

By employing sodium sulphite as "fixing" agent for the acetaldehyde formed in alcoholic fermentation an equivalent amount of glycerol is also produced. More than 70% of the theoretical amount of acetaldehyde is thus fixed. The amount of acetaldehyde and glycerol produced increases with the amount of sulphite employed. Acetaldehyde and glycerol are therefore not only by-products but are formed in considerable quantities in certain stages of alcoholic fermentation.—S. S. Z.

Wines; Blue "casse" of —. P. Carles. *Comptes rend.*, 1919, 169, 1422—1423.

THE blue or ferric "casse" of wines cannot be entirely prevented by the presence of sulphur dioxide. The best treatment consists in the addition to the wine of tartaric or citric acid, the amount to be added varying with the intensity of the evil, and in order to determine it the best way is to make a preliminary trial by adding 50 grms. per hectolitre and to increase the amount, if necessary, progressively up to 150 or 200 grms. in the case of certain wines.—W. G.

Soluble starch; Formation of — in selective nitrogen assimilation [by moulds]. F. Boas. *Ber. Deut. Botan. Ges.*, 1919, 37, 50—56. *Chem. Zentr.*, 1919, 90, 111., 888—889.

At a certain hydrogen ion concentration soluble starch is formed from many carbohydrates by *Aspergillus niger*. If in a sugar solution ammonium chloride is consumed as well as amino-acids by the fungus, the liberation of the strongly dissociated hydrochloric acid rapidly increases the hydrogen ion concentration giving conditions favourable for the formation of soluble starch, and the iodine test affords a means of following the selective nitrogen assimilation. In mixtures of ammonium chloride with ammonium phosphate and citrate, with amino-acids and peptone, or with urea, it is the ammonium chloride which is attacked, that is, the mould utilises the least favourable source of nitrogen. With mixtures of nitrogenous substances having different degrees of dissociation, the magnitude of the dissociation controls the absorption into the cell; this absorption is not regulated by the mould, and is the result of purely physico-chemical processes.—W. P. S.

Mould spores; Do — contain enzymes? N. and L. Kopeloff. *J. Agric. Res.*, 1919, 18, 195—209.

A suspension of the spores of the mould under investigation was heated to 63° C. to kill the spores, and then shaken with sand to rupture the spore wall. A measured quantity of this suspension was added to a 10% sucrose solution and incubated at 45° C. After 3 hrs. the solution was examined in a polarimeter and tested for reducing sugar; a decrease in rotation and production of reducing sugar were observed. Upon further incubation for 1 and 4 days increasing changes occurred. If double the amount of the spore emulsion was taken, the amount of change was increased, and with a 20% sucrose solution the changes were more marked. The above results were obtained with the spores of *Aspergillus niger* and *sydowi*, *Aspergillus flavus* and *Penicillium expansum* acted similarly but more feebly. The suspension of spores after heating at 100° C. had no effect on the sucrose solution. The cause of the changes was therefore an enzyme identical with invertase. The upper limit of concentration for the sugar solution was found to be 18—24%, using a suspension containing 100,000—400,000 spores per c.c.—J. H. J.

Catalase of bacteria. M. Jacoby. *Biochem. Zeits.*, 1918, 92, 129—139.

THE catalase of bacteria obtained by the author obeys the same reaction laws as the catalases previously studied (this J., 1918, 557 A, 667 A).

Chinese ang-khak [red rice]. Church. See XIXa.

PATENTS.

Yeasts; Process for stimulating fat-formation in —. Kriegsausschuss für pflanzliche und tierische Öle und Fette, G.m.b.H., Berlin. Ger. Pat. 307,789, 11.8.17.

IN the cultivation of yeast incapable of film formation, for the purpose of producing fats, the yeast is maintained at the surface of the nutrient liquid by means of a diaphragm, so as to realise artificially the conditions of film growth. The nutrient liquid may be charged with oxygen, e.g., by aerating it or treating it with hydrogen peroxide or per-salts before use.—J. H. L.

Yeast; Process of manufacture of pressed — from worts containing little or no sugar. Verein der Spiritus-Fabrikanten in Deutschland, Berlin. Ger. Pats. 314,163—314,166, (A) 24.6.13, (B) 25.6.13, (c) 18.7.13, (d) 11.5.15. Additions to Ger. Pat. 310,461 see Fr. Pat. 472,073 of 1914; this J., 1915, 444).

(A) THE worts are pitched with mixed yeasts, in particular with mixtures of distillery yeasts with mycoderma yeasts. (B) In preparing worts by transforming the sugars present into acid (lactic acid), alkalis are added to combine with the latter. When the acidification process is complete the lactic acid is liberated by means of an organic acid, and the worts are suitably diluted. (C) Worts may be prepared by subjecting to the acidification process waste liquors from the manufacture of cereal starch, or liquors actually containing starch in ungelatinised state, the starch being afterwards recovered from the acid liquors and the latter employed for yeast production. (D) The acidified worts are treated with sugar and inorganic ammonium salts in such quantities that the lactic acid destroyed by the yeast is replaced by the mineral acid liberated by the assimilation of ammonia. A mixture of sugar and inorganic ammonium salts with lactates may be employed for yeast production, the mineral acid liberated from the ammonium salts setting free lactic acid from the lactate for the use of the yeast.—J. H. L.

XIXA.—FOODS.

Milk; Influence of the acidity of — on the velocity of inactivation of the peroxidase by heat. A. Bouma and W. van Dam. *Biochem.-Zeits.*, 1918, 92, 385–397.

THE influence of the hydrogen ion concentration on the inactivation of the peroxidase in milk at 70.55° C. was studied. At 70° C. p_H is 2½–3 times higher than at the ordinary temperature. The addition of so much lactic acid to the milk as was just insufficient to curdle it on pasteurisation had no effect on the velocity constant of the inactivation of the enzyme at that temperature. On the other hand, the addition of sodium hydroxide and ammonia greatly accelerated the destruction of the peroxidase. This confirms the observations previously made by Zilva (this J., 1915, 98).

—S. S. Z.

Lactose in altered milk; Estimation of —. E. Hildt. *Bull. Soc. Chim.*, 1919, 23, 617–621.

A MORE detailed account of work already published (see this J., 1919, 51A).—W. G.

Butter; New method for detecting adulteration in — and for estimating fats of the coconut group. G. van B. Gilmour. *Analyst*, 1920, 45, 2–7.

A METHOD for distinguishing between butter fat and fats of the coconut group has been based on a fractionation of the volatile fatty acids into two groups according to their solubility in saturated brine. Twenty grms. of the filtered fat is saponified, and the volatile fatty acids distilled as in Blichfeldt's method and using his apparatus (this J., 1919, 150D). The distillate is neutralised with N/10 sodium hydroxide solution, a correction of 0.4 c.c. being made for the blank determination, and the neutral soap solution is treated with a quantity of N/10 sulphuric acid equal to that of the sodium hydroxide used ($T + 0.4$), and then with 61 grms. of pure, dry sodium chloride which is neutral to phenolphthalein. The flask is closed and shaken, the contents made up to 200 c.c., and filtered, and 190 c.c. of the filtrate titrated with N/10 sodium hydroxide. The number of c.c. required, multiplied by ¾, and 0.4 (for a blank) deducted from the product represents the soluble volatile acids (S), whilst T–S represents the insoluble volatile acids (I). The variations observed in the case of 12 samples of butter fat were:—T from 26.0 to 33.0; S, from 20.0 to 23.5; and I from 5.0 to 9.5. Six samples of coconut fat gave: T, 19.5 to 22.5; S, 1.3 to 1.8; and I, 18.0 to 20.7. Six samples of palm-kernel fat gave: T, 12.0 to 14.0; S, 1.0 to 1.3; and I, 11.0 to 12.7; and a sample of babassu fat gave: T, 14.3; S, 1.2; and I, 13.1. Using average figures for pure butter, coconut, and palm-kernel fats, the following equations enable the percentage of any one of the three fats in a mixture to be calculated directly:—

(1) Per cent. butter fat = $4.678 - 0.351x$.

(2) Per cent. coconut fat = $51 - 0.38x$.

(3) Per cent. palm-kernel fat = $7.691 - 0.59x$.

Results obtained with mixtures containing arachis oil in addition to the above fats are also given.

—C. A. M.

Cereals; [Determination of] moisture content of —. O. A. Nelson and G. A. Hulett. *J. Ind. Eng. Chem.*, 1920, 12, 40–45.

THE method described is a modification of that used previously by Hulett, Mack, and Smith (this J., 1918, 230A) for the determination of moisture in coals (see also Mack and Hulett, this J., 1917, 378), and consists essentially in heating the material in a very high vacuum produced by a Töpler pump for definite periods of time. The

temperatures employed ranged from 100° to 237° C., and the gases other than water vapour (this was frozen in the receiver surrounded with solid carbon dioxide) evolved at the higher temperatures were collected. It was thus possible to ascertain to what temperature and for what length of time a substance could be heated without yielding an appreciable amount of water due to decomposition. For cereals and cellulose the heating may be continued for 5 hrs. at 180° C. without appreciable decomposition.—W. P. S.

Ang-khak [red rice]; Experiments on the manufacture of Chinese — in the United States. M. B. Church. *J. Ind. Eng. Chem.*, 1920, 12, 45–46.

CHINESE red rice, or ang-khak, is obtained by inoculating moist rice grains with the fungus *Monascus purpureus*, Went.; after a short time, the grains are impregnated with mould hyphae which produce the red colour. The red grains are readily crumbled between the fingers and impart a clear carmine colour to any moist food substance to which they are added. *Monascus purpureus*, Went., although utilised in this way only in China, has been obtained in America from ensilage and “freckled” codfish. All strains of the fungus are not adapted to the production of red rice, since each varies in its physiological activity, its action on rice, and the “richness” of the colour it produces.—W. P. S.

Vitamines of green foods. T. B. Osborne and L. B. Mendel. *J. Biol. Chem.*, 1919, 37, 187–200.

SPINACH, cabbage, alfalfa (lucerne), clover, and timothy plants are not very rich in the water-soluble vitamins, but constitute valuable sources of the fat-soluble factor.—J. C. D.

Foods; Influence of high temperatures and dilute alkalis on the anti-neuritic properties of —. A. L. Daniels and N. I. McClurg. *J. Biol. Chem.*, 1919, 37, 201–213.

THE authors do not agree with McCollum and Simmonds (this J., 1918, 134A) and Chick and Hume (this J., 1918, 17A) that the anti-neuritic vitamin is very unstable. They contend that no great depreciation in the value of foods takes place during the usual processes of canning.—J. C. D.

Jams, preserves and marmalade; [Determination of] insoluble solids in —. C. A. Clemens. *J. Ind. Eng. Chem.*, 1920, 12, 48–49.

TWENTY grms. of the sample is mixed with 100 c.c. of water, boiled for 5 mins., and filtered through an alundum crucible to which suction is applied. The insoluble residue is washed with boiling water, then with alcohol and ether, dried, and weighed.

—W. P. S.

Coconut (Cocos nucifera); Globulin of —. C. O. Johns, A. J. Finks, and C. E. F. Gersdorff. *J. Biol. Chem.*, 1919, 37, 149–153.

A DETAILED method for the preparation of the globulin from the coconut is described. This protein contains a fairly high percentage (15.92) of arginine.—J. C. D.

Jack bean; Globulin of —. J. B. Sumner. *J. Biol. Chem.*, 1919, 37, 137–142.

THE author describes three globulins which he has isolated from this bean. Two are obtainable in crystalline condition. (See further, *J. Chem. Soc.*, 1920, i., 210.)—J. C. D.

Alfalfa [lucerne]; Losses of organic matter in making brown and black —. C. O. Swanson, L. E. Call, and S. C. Salmon. *J. Agric. Res.*, 1919, 18, 299–301.

WHEN partially wilted lucerne is stacked without

curing it undergoes fermentation producing brown and black hay. Analyses of samples from a stack of this nature were made for ash, protein, fibre, and extract, and compared with similar analyses of the original lucerne. It was found that about two-fifths of the organic matter had been lost, and that further losses took place on further standing. Feeding experiments were made with the brown and black material, which showed the black lucerne to be very inferior to the brown and to sound lucerne as a food for cattle.—J. H. J.

Sunflower silage. R. E. Neidig and L. E. Vance. *J. Agric. Res.*, 1919, 18, 325—327.

A CROP of sunflowers was made into silage and examined after four months' storage. At a depth of 9 ft. the colour and odour of the silage were very good, and the amount of volatile acids, chiefly acetic acid, was 3.79%, and of lactic acid 3.45% of the dried sample. The average amount of moisture was 78.5%, ash 2.4%, protein 2.4%, fibre 5.8%, nitrogen-free extract 9.8%, and ether extract 1.1%. —J. H. J.

Pentosans; Modification of the phenylhydrazine method of determining —. P. Menual and C. T. Dowell. *J. Ind. Eng. Chem.*, 1919, 11, 1024—1025.

PHENYLHYDRAZINE may be determined, like hydrazine (see Ebler, this J., 1905, 1257), by interaction with ammoniacal copper sulphate solution and measurement of the volume of nitrogen evolved. The authors applied this reaction to the determination of pentosans, to avoid the use of phloroglucinol, which is now difficult to obtain; the amount of furfural produced was found by precipitating with a known excess of phenylhydrazine, filtering, and determining the excess of phenylhydrazine in the filtrate. As chlorides interfere with the action of the copper reagent the original material was distilled in presence of sulphuric acid instead of hydrochloric acid, the volume of liquid in the flask being kept practically constant by addition of water from time to time. An aliquot part of the distillate was treated with a known excess of phenylhydrazine and agitated for the required period by bubbling carbon dioxide through it. After filtration, an aliquot part of the filtrate (50 c.c.) was introduced by means of a dropping funnel into a 250 c.c. Fresenius nitrogen bulb, which had been previously filled with a 10% solution of ammoniacal copper sulphate and heated to expel the air. A 100 c.c. burette was connected to the tube of the Fresenius bulb, and a glass tube provided with a stopcock connected the neck of the bulb to a Schiff's nitrometer containing sulphuric acid. The 50 c.c. of filtrate was introduced into the bulb through the dropping funnel by closing the cock leading to the nitrometer and lowering the burette. The bulb was then heated to keep the reaction mixture near the boiling point until the reaction was complete. From the volume of nitrogen obtained the excess of phenylhydrazine used was calculated. In 1 grm. of a sample of sorghum 0.1526 grm. of pentosans was found by this method and 0.1523 grm. by the phloroglucinol method; with two other samples still smaller differences were obtained. The time occupied in making a determination of the excess of phenylhydrazine in the filtrate from the hydrazone was 20 mins.—J. H. J.

Citric acid. Broeksmitt. See XX.

PATENTS.

Feeding stuffs from marine plants [seaweed] and processes for manufacturing the same. D. Cronstoe and H. F. Warnecke, Stockholm, Sweden. Eng. Pat. 121,295, 5.12.18. (Appl. 20,197/18.)

SEAWEED is washed, treated with steam under pressure, pressed, dried under reduced pressure, and

ground; the expressed liquor is concentrated at a low temperature under reduced pressure, the crystallised salts are separated in a centrifuge, the liquor added to the ground cake, and the mixture again dried under reduced pressure and pressed into cakes. The product contains, approximately, water 5, proteins 13, digestible carbohydrates 67, fat 1, cellulose 9, and mineral substances 5%.

—W. P. S.

Margarine or the like; Apparatus for use in the manufacture of —. S. H. Blichfeldt, Southall, Middlesex. Eng. Pat. 135,939, 4.12.18. (Appl. 20,079/18.)

IN the manufacture of margarine according to the methods described in Eng. Pats. 4278 and 17,616 of 1913 (this J., 1913, 921; 1914, 883), the heating or working of the material may be carried out in a rotating drum mounted on an inclined axis, the outlet being at the lower end. Means are provided for adjusting the degree of inclination of the axis.

—W. P. S.

Food product containing cocoa. P. Kestner, Paris. Eng. Pat. 136,205, 14.9.18. (Appl. 14,970/18.)

A MIXTURE of cocoa and non-caramelised concentrated sugar-beet juice from which substances having an unpleasant taste and odour have been removed (see Eng. Pat. 135,235; this J., 1920, 76A); the mixture may be flavoured with vanilla, cinnamon, etc.—W. P. S.

Foodstuffs; Animal — [from garbage]. F. W. Gee, Harrow. Eng. Pat. 136,237, 7.12.18. (Appl. 20,363/18.)

A MIXTURE of vegetable and animal or fish offal is heated at 250°—260° F. (121°—127° C.) in a steam-jacketed pan until the moisture content is reduced to about 30%; the mass is then mixed with 20—25% of its weight of farinaceous material (e.g., bakers' sweepings), and the mixture is baked.—W. P. S.

Animal waste; Process for treating nitrogenous —. E. C. R. Marks, London. From C. F. Hildebrandt, Hamburg, Germany. Eng. Pats. (A) 136,853 and (B) 136,854, 14.11.17. (Apples. 16,735 and 16,736/17.)

(A) A MIXTURE of 300 parts of water and 80 parts of hydrochloric acid (sp. gr. 1.15) is heated in a digester, and 100 parts of hair, cartilage, etc., is gradually added. The mass is agitated at 100°—110° C. for three hours. It is then neutralised with soda and concentrated in a vacuum. (B) In order to effect the removal of any substances which would impart a bad smell to the finished product, the raw material is extracted with ether or other fat solvent, or it may be subjected to the action of live steam. The same effect may be produced by submitting the solution obtained by treatment of the waste with acid in the digester to a thorough boiling. The products are similar to meat extracts.

—J. H. J.

Fruit juices; Process for treating —. G. F. Hieber, Spokane, Wash. U.S. Pat. 1,325,094, 16.12.19. Appl., 21.10.18.

THE juice is passed through a preheater into a sterilising vessel provided with a stirrer; on leaving the sterilising vessel the hot juice circulates through a jacket surrounding the preheater, thus heating a fresh quantity of juice in the latter, and is then drawn off, cooled, and stored.—W. P. S.

Bread; Manufacture of leavened —. H. A. Kobman, R. Irvin, and R. J. Cross, Pittsburgh, Pa., Assignors to The Ward Baking Co., New York. U.S. Pat. 1,325,327, 16.12.19. Appl., 11.2.19.

A SUBSTANCE containing diastatic and proteolytic enzymes, produced by the action of a fungus on

carbohydrates and proteins, is added to the yeast, flour, and other ingredients of the dough.

—W. P. S.

Meat extract and the like; Preparation of —. Chem. Ges. Rhenania, Wevelinghoven. Ger. Pat. 315,365, 6.2.17.

CARBON dioxide, under pressure if necessary, is led into the autoclave or other vessel during the extraction. By this procedure the formation of ammonia and decomposition of degradation products of the proteins is reduced, and an extract is obtained with an increased content of amino-acids; this has an important influence on the taste and smell of the extract.—D. F. T.

Bean flour; Process of deodorising and decoloring —. Y. Yamamoto, I. Mizusawa, and T. Kano, Kobe, Japan. Eng. Pat. 136,775, 24.6.19. (Appl. 15,904/19.)

Cheese; Process of sterilising — and an improved product produced by such process. J. L. Kraft, Chicago, Ill., Assignor to J. L. Kraft and Bros. Co. Reissue 14,777, 23.12.19, of U.S. Pat. 1,186,524, 6.6.16. Appl., 18.10.19.

SEE this J., 1916, 861.

XIXb.—WATER PURIFICATION; SANITATION

Bacterium coli; Detection of — in drinking water. J. W. de Waal. Pharm. Weekblad, 1919, 56, 1065—1070.

DIVERSITY of opinion exists in regard to the universal distribution of coli bacilli in drinking water. To some extent the varying experiences may be explained by the different methods of examination employed, as also by the amounts of the samples tested. Further, there is not complete uniformity of opinion in regard to some subsidiary characteristics of *B. coli*, such as indole formation. The chief property distinguishing this bacillus is the decomposition of lactose with formation of gas and acid. The breaking up of the dextrose molecule at 37° C. is not confined to *B. coli*. Tests were carried out with a culture in which ox gall was used instead of sodium taurocholate, and a solution was made of peptone 1%, lactose 0.5%, ox gall 3%, and litmus solution 2.5%. The isolation of the bacilli was effected by means of the same preparation, with the addition of agar, and the test was completed in 96 hours.—W. J. W.

Sewage purified by the activated sludge process; Bacterial flora of —. P. Courmont and A. Rochaix. Comptes rend., 1920, 170, 75—78.

THERE is a considerable reduction of the microbial flora in the activated sludge process of sewage purification. One sample examined before purification contained 202,500,000 microbes per c.c., and only 67,587 after purification. The other sample only examined after purification contained then 58,600 per c.c. All the microbial species left after purification were aerobic, no strictly anaerobic organisms being left, and thus apparently all the putrefactive organisms are destroyed. In both cases the flora remaining was very simple, only seven species being isolated and, of these, five were chromogenic. The purified effluent does not appear to contain either *B. coli* or any other known pathogenic organism.—W. G.

Gentian Violet: its selective bactericidal action. M. L. Crossley. J. Amer. Chem. Soc., 1919, 41, 2083—2090.

COMMERCIAL Gentian Violet is a mixture of equal parts of dextrin and dye, which latter consists

chiefly of hexamethyl- and pentamethyl-*p*-rosaniline hydrochlorides with a small amount of the tetramethyl compound and lower homologues. The selective bactericidal action of Gentian Violet is no greater than that of its component dyes and Gentian Violet has no advantage over these in selective or differentiating power. Organisms which were gentian positive were also gram positive and *vice versa*, the structure both of the dye and the organism being important factors in the selective action. The concentration of the dye is an important factor in determining its power to kill an organism. Not one of the dyes examined was effective against *B. subtilis* in dilutions greater than 1 in 100,000. *B. mycoides* was killed, however, by Malachite Green at a dilution of 1 in 100,000, by resaniline at a dilution of 1 in 200,000, and by Gentian Violet or either of its two principal components at a dilution of 1 in 300,000. The basic nitrogen groups appear to be the reactive groups and their action is intensified by substitution of methyl for amino hydrogen.—W. G.

Timber and plants; Laboratory tests on the value of preservatives for —, and a new solution for spraying plants. R. Falek. Z. angew. Botanik, 1919, [11 and 12]. Chem.-Zeit., 1919, 43, Rep., 313.

PURE cultures of wood-destroying fungi were cultivated on a broth-wart-agar medium, and the rate of growth was measured accurately for different concentrations; portions of the cultures were then added to wood impregnated with various preservatives to determine the efficiency of each as a means for protecting the wood against the fungi. Only strong preservatives in high concentration were found to be sufficiently reactive; sodium fluoride, 2,4-dinitrophenol, dinitro-*o*-cresol, and mixtures of 85–95 parts of sodium fluoride with 15–5 parts of the dinitrophenol or nitro-*o*-cresol, were found to be among the most efficient. These preservatives however, particularly sodium fluoride, when used in dilute solutions, have very little effect upon the spores of saprophytes and parasitic fungi. Copper hydroxide, also, which is much used for spraying plants, is of no use for the preservation of wood. The author recommends a 10% “resinol”-lime or “resinol”-magnesia spray liquor. Either of the liquors can be applied readily to any parts of plants. They are freshly prepared for use by adding either 300 c.c. of calcium chloride solution (sp. gr. 1.14) or 125 grms. of magnesium sulphate in 5 litres of water to 300 c.c. of a concentrated alkaline solution of “resinol” in 5 litres of water. The experimental work has all been carried out in the laboratory, and the results have yet to be tested in actual practice.—L. A. C.

Chloropicrin; Comparative action of — on the weevil and the tribolium. G. Bertrand, Brocq-Rousseau, and Dassonville. Comptes rend., 1919, 169, 1428—1430.

THE tribolium is much more resistant than the weevil to the action of chloropicrin and this affords a means of separating the two parasites. This applies both to the isolated parasites and when they are present in maize.—W. G.

PATENTS.

Water; Process for separating air and other gases from —. C. Hülsmeier, Düsseldorf-Grafenberg. Ger. Pat. 311,336, 3.7.14.

A FILTER-BED for removing air and other gases from water consists of a number of loosely packed layers of iron borings and wood or animal charcoal arranged alternately. Compared with the same quantity of materials arranged as a single layer of iron borings with a layer of charcoal on top, the

series of alternate layers is more efficient, does not exhaust so rapidly, and is more readily cleaned.

—L. A. C.

Sewage sludge; Method of concentrating —. J. Grossmann, Manchester. U.S. Pat. 1,325,787, 23.12.19. Appl., 6.10.14.

SEE Eng. Pat. 22,778 of 1913; this J., 1914, 981.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Nicotine; Quantitative biological method for the estimation of —. H. Fühner. Biochem.-Zeits., 1918, 92, 355—364.

By means of the contraction produced by the action of nicotine on the plain muscle of the leech, it is possible to estimate quantitatively 0.01 mgrm. of the alkaloid. The myograph of the nicotine solution of unknown strength is compared with that of a solution of known strength.—S. S. Z.

Physostigmine; Toxicological detection of —. H. Fühner. Biochem.-Zeits., 1918, 92, 347—355.

QUANTITIES of 0.005—0.01 mgrm. of physostigmine can be detected by means of the biological eye-reaction in the cat. The author finds that in the case of the plain muscle of the leech minute quantities of physostigmine in the presence of acetylcholine increase, the contraction of the muscle brought about only to a small extent by acetylcholine alone. By this joint action of the two drugs on the muscle of the leech 0.0001 mgrm. of physostigmine can be detected with certainty.—S. S. Z.

Digitalis; Pharmacology of compounds resembling — in their activity. M. Walter. Biochem.-Zeits., 1918, 92, 267—282.

THE diffusibility, electrical charge, adsorption, and the reversibility of the action on the heart of compounds resembling digitalis in their activity were studied. No connection between these properties could be established.—S. S. Z.

Polygonaceae; Properties of the —. [Determination of hydroxyanthraquinone derivatives.] A. J. Steenhauer. Pharm. Weekblad, 1919, 56, 1084—1101.

THE botanical structure of the leaves of various plants of the Polygonum order is described. Their chemical components have been investigated to a limited extent only. The author gives methods for extraction of these. Anthraquinone derivatives are found in several species. For the estimation of hydroxyanthraquinone derivatives a colorimetric method is most suitable; 0.6 gm. of powdered material is boiled for 1 hour in an Erlenmeyer flask with a reflux condenser with 15 c.c. of dilute sulphuric acid. After cooling the mixture is transferred to a flask of 125 c.c. capacity, 90 c.c. of benzene is added, and the mixture is well agitated for 3 hours; 3 grms. of tragacanth powder is then added, and after again shaking, 75 c.c. is filtered off (=0.5 gm. material) and shaken with 5% potassium hydroxide. The liquid is made up to a suitable volume, filtered, and its strength determined by comparison with a solution of emodine in 5% potassium hydroxide (1:1,000,000) or a solution of nickel (1:250,000).—W. J. W.

Balsams; Examination of various —. L. van Itallie. Pharm. Weekblad, 1919, 56, 1185—1201.

THE authors have collected, and themselves contribute, many data in regard to numerous balsams, including *balsamum copaiva*, *balsamum toluatanum*,

balsamum peruvianum. Their reactions and properties are tabulated and discussed at some length.

—W. J. W.

Toxins and their antitoxins; Mutual precipitation of —. Application to the titration of antidiphtheric and antitetanic sera. M. Nicolle, E. Debains, and E. Césari. Comptes rend., 1919, 169, 1433—1434.

THE technique is as follows: The filtrates of the diphtheric and tetanic cultures are saturated with anhydrous sodium sulphate, the precipitates obtained being dried *in vacuo* over sulphuric acid and reduced to homogeneous powders. 0.8 gm. of the powder is dissolved in 10 c.c. of distilled water and mixed with an equal volume of a previously melted 10% solution of gelatin in "physiological water." The mixture is distributed in a number of test-tubes, 1 c.c. in each, and cooled in an ice-chest. To these tubes in series is added 1 c.c. of the antitoxic serum at varying dilutions, 1/20, 1/50, 1/100, etc. After two hours at the ordinary temperature the tubes are examined, a positive result being indicated by the appearance of a white disc at the junction of the gelatin and the serum. It is important that the toxic solution and the serum should both be absolutely limpid. Antidiphtheric sera containing 300 units per c.c. and antitetanic sera containing 4000 units per c.c. both give positive results at a dilution of 1/50.—W. G.

Halogenation XIX. Replacement of sulphonic groups by chlorine and the preparation of organic chloro-derivatives. R. L. Datta and H. K. Mitter. J. Amer. Chem. Soc., 1919, 41, 2028—2038.

WHEN chlorine is passed into an aqueous solution of a sulphonic acid the sulphonic group is readily replaced by chlorine with very good yields. In some cases additional chlorination occurs. Aromatic compounds, which in addition contain a hydroxy group exhibit a special facility for this change, and the same has also been found true of amino compounds, such as the nitroanilines. (See further J. Chem. Soc., 1920, i., 157.)—W. G.

Sulphonic groups; Replacement of — by nitro groups by means of nitrous gases. R. L. Datta and P. S. Varma. J. Amer. Chem. Soc., 1919, 41, 2039—2048.

THE sulphonic groups in aromatic compounds may be very easily replaced by nitro groups by the action of nitrous gases. In the course of the action more nitro groups frequently enter with the formation of highly nitrated compounds. The action is generally effected in aqueous solution, the nitrous gases being passed in to saturation, and it may immediately follow the sulphonation without the preliminary isolation of the sulphonic acid. Many nitrations which cannot be brought about at all by nitric acid can be readily accomplished by this method. In general, aromatic compounds which are already substituted by hydroxy groups or by halogens readily undergo this replacement of the sulphonyl group by a nitro group, in some cases more nitro groups entering the ring in suitable positions. In the case of the hydroxycarboxylic acids both the carboxyl and the sulphonyl groups are replaced by nitro groups. If, however, the compound does not contain either substituted halogens or hydroxyl groups, replacement of the sulphonyl group does not take place at all. Thus, benzenesulphonic acid is not affected by treatment with nitrous gases.—W. G.

Nitrous esters and nitro compounds; Direct conversion of — into nitriles by catalysis. A. Mailhe and M. L. Bellegarde. Bull. Soc. Chim., 1919, 25, 588—593.

By passage of their vapours with hydrogen over

reduced nickel at 300° C., or a slightly higher temperature the nitrites (isoamyl, propyl, and heptyl) and nitro-compounds (nitromethane and nitropentane) examined were converted into the corresponding nitriles. The change is not complete, as a certain amount of amine, which escapes dehydrogenation, passes over, and in the case of the nitrates a portion of the ester undergoes hydrolysis by the water formed, giving the corresponding alcohol.

—W. G.

Amines; Iodination of aromatic — by means of iodine and persulphate. K. Elbs and H. Volk. *J. prakt. Chem.*, 1919, 99, 269—275.

VERY limited success has attended the application of this method (this J., 1913, 766) to aromatic amines and their acyl derivatives. The yields of 2-iodo-*p*-toluidine, 2-iodo-*p*-nitraniline, and 2,4-di-iodo-*o*-nitraniline were good; of 2-iodo-*p*-toluidine and 2-iodo-sulphanilic acid moderate; of 2,4-di-iodoaniline (accompanied by *p*-iodoaniline), *p*-iodo-acetanilide, and 3-iodo-*p*-bromoaniline poor. Indefinite products were obtained in other cases. Reference is made to unpublished experiments in which excellent results were obtained with anisole and phenetole. (See further *J. Chem. Soc.*, 1920, i., 154.)—J. K.

Veronal, luminal, and propional; Microchemical reactions of —. L. van Itallie and A. L. W. E. van der Veen. *Pharm. Weekblad*, 1919, 56, 1112—1117.

If small traces of veronal (diethylbarbituric acid), luminal (phenylmethylmalonylurea), and propional (dipropylbarbituric acid) are present in urine they may be isolated by treatment with lead acetate and hydrogen sulphide and obtained in a form suitable for identification by sublimation. Monoclinic crystals of veronal are obtained when its sodium hydroxide solution is treated with an acid, potassium bichromate, or ammonium phosphate. Lead acetate gives an amorphous mass which becomes crystalline on boiling. An irregular crystalline mass of compound crystals is obtained by addition of ammoniacal silver nitrate, and similarly, veronal thallium crystals are produced by treatment of the solution with thallium nitrate. Luminal and propional have been separated in the free state only. Ammonium phosphate causes their separation as drops, which very slowly acquire a crystalline state. Luminal and propional crystals probably belong to the rhombic class.—W. J. W.

Urea and hypobromite. L. Lescœur. *J. Pharm. Chim.*, 1919, 20, 305—314, 343—351, 374—381.

A CRITICAL examination of the reaction between urea and alkaline hypobromite solution showed that there is always a deficit in the quantity of urea found, whether it be calculated from the volume of nitrogen liberated, the carbon dioxide formed, or the hypobromite used in the reaction. The larger the proportion of free alkali to urea the smaller is the deficit, but the theoretical yield is never obtained. The loss appears to be due to the conversion of a small portion of the urea into sodium cyanate.—W. P. S.

Guaiaicol; Specific gravity of —. J. Colman-Nicoresti. *Pharm. J.*, 1920, 101, 26.

VARIOUS samples of guaiaicol had sp. gr. ranging from 1.111 to 1.130 at 15° C., whereas the B.P. standard is 1.16—1.20. The value given by the U.S. Pharmacopœia is 1.110—1.114 at 25° C., whilst other authorities give values ranging from 1.116—1.143. The most correct value is probably 1.143 (Béhal and Choay, this J., 1893, 618), which was obtained with synthetically prepared guaiaicol. Since the commercial product is largely prepared

from cresol, and will probably contain traces of phenol, which are difficult to remove, a somewhat lower sp. gr. than 1.143 should be permissible.

—C. A. M.

Acrolein; Stabilisation of —. V. *Stabilising action of substances with a phenolic group.* C. Mourou, C. Durraisse, P. Robin, and J. Pougnet. *Comptes rend.*, 1920, 170, 26—31. (See this J., 1919, 923 A; 1920, 42 A, 82 A.)

Or the monohydric phenols examined a naphthol showed the strongest stabilising action. The presence of additional hydroxy groups in the nucleus caused a notable increase in the stabilising power, except when two hydroxy groups were in the meta position to one another. The methyl ethers and the acetyl derivatives of the phenols did not show any stabilising action, and this is also true of mono- or polyhydric alcohols. The property is thus peculiar to the phenolic group as such. The stabilising power of the hydroxybenzoic acids was intermediate between that of benzoic acid and the corresponding phenols. Not only do the phenols and particularly the polyphenols inhibit the formation of insoluble resin (disacryl), but they also exert a strong inhibiting effect against the formation of soluble resin, even when the phenols are only present in the acrolein to the extent of 1 in 4000.—W. G.

Citric acid; Detection of free and combined —. T. C. N. Brooksmit. *Pharm. Weekblad*, 1919, 56, 1047—1052.

Citric acid is determined in acetic acid solution by oxidation with permanganate and formation of iodoform. Potassium acetate added to an alcoholic solution gives a clear solution with citric acid, but a precipitate with tartaric acid. Barium acetate precipitates citric acid from alcoholic solution. Details are given for the detection of citric acid in fruit juices and milk, and in its compounds—e.g., in citrates, *citras caffeini*, *citras ferricus et citras chinini*, *pyrophosphas ferricus cum citrate ammonico*, *citrophene*, *migrainum*.—W. J. W.

Carvomenthols; Isomeric — and resolution of inactive carvomenthol into the optical antipodes. I. and H. V. Paolini. *Atti R. Accad. Lincei*, 1919, [v.], 28, ii., 82—85, 131—137.

From the inactive carvomenthol obtained by the reduction of carvenone, the levo-isomeride may be isolated by crystallisation of the less soluble of the two carvomenthol strychnine phthalates and conversion of this into *l*-carvomenthol hydrogen phthalate and the latter into *l*-carvomenthol. The carvomenthol hydrogen phthalate prepared from the mother liquors of the above strychnine salt is syrupy, but when treated with the calculated proportion of ammonia and with silver nitrate, it yields insoluble silver *d*-carvomenthol phthalate and from this, by way of sodium *d*-carvomenthol phthalate and *d*-carvomenthol hydrogen phthalate, *d*-carvomenthol may be isolated. The properties of the various products are described. (See also *J. Chem. Soc.*, 1920, i., 170.)—T. H. P.

Hydrastis, Cola, and Strychnos; Analysis of preparations of —. L. M. van den Berg. *Pharm. Weekblad*, 1919, 56, 1124—1134.

Alcohol or ether from coal distillation gases. De Loisy. See IIa.

Electrolytic decomposition of organic acids. Heinrich and Schenk. See XI.

Iodometric estimation of acids. Kolthoff. See XXIII.

PATENTS.

Calcium citrate; Purification of — and manufacture of citric acid. H. D. Golding, J. Raschen, and United Alkali Co., Liverpool. Eng. Pat. 136,979, 20.3.19. (Appl. 6928/19.)

CALCIUM citrate is purified by treatment with sulphurous acid whereby a solution of citric acid and calcium bisulphite is produced; after the removal of insoluble organic matter, the solution is boiled with resulting loss of sulphur dioxide and re-formation of calcium citrate which separates as a precipitate. From this the citric acid is obtained by decomposition with dilute sulphuric acid. In obtaining citric acid from lime-juice or lemon-juice the solution is treated as above but with calcium bisulphite in place of sulphurous acid in the first operation.—D. F. T.

Cyanamide; Process of converting — into urea and ammonium compounds. S. Giertsen, Odda, Norway. U.S. Pat. 1,326,045, 23.12.19. Appl., 22.8.19.

CYANAMIDE is converted into urea by heating under pressure with aqueous sulphurous acid.—D. F. T.

Urea; Production of — from cyanamide. Farbwerk, Meister, Lucius, und Brüning, Höchst. Ger. Pats. (A) 311,018, 14.3.16, and (B) 311,019, 17.3.16.

(A) THE cyanamide is treated in acid solution with finely divided hydrated manganese dioxide, which is added in quantities smaller than the weight of nitrogen in the dissolved cyanamide. (B) Limited quantities of other hydrated oxides, produced *in situ* if necessary, may be used in place of manganese dioxide; e.g., stannic oxide, introduced in the form of pink salt (ammonium stannichloride), lead dioxide, chromium hydroxide, and ferric hydroxide.—D. F. T.

Camphor; Process for the production of synthetic —. R. L. Andreau, Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,326,248, 30.12.19. Appl., 27.2.17.

ISOBORNEOL is oxidised to camphor by heating to 75°–86° C. with nitric acid free from substances capable of inducing vigorous oxidation of the isoborneol by nitric acid at 40° C.; when the reaction has well started the temperature is reduced materially below 75° C.—L. A. C.

Glanders and oedema; Process for the production of preventive and curative agents for —. M. Piorkowski, Berlin. Ger. Pat. 302,405, 17.2.15. Addition to Ger. Pat. 302,404.

CULTURES of the bacteria of oedema or glanders prepared as described in the chief patent (this J., 1919, 963 A) after being maintained for several days at about 42° C., are heated by stages to 110° C. and dried.—L. A. C.

Oralic acid; Preparation of — from sugar and other carbohydrates. Kinzberger und Co., Prague. Ger. Pat. 310,923, 9.2.16. Int. Conv., 6.7.15.

PREVIOUS to oxidation by one of the customary processes employing nitric acid or oxides of nitrogen and a catalyst, the carbohydrate mass (wood excepted) is submitted to a preliminary treatment with nitrous fumes below 60° C. In this way the rate of the subsequent oxidation is moderated and any sudden development of heat avoided.—D. F. T.

Hydroxytrimethyleneglycine; Preparation of —. H. Krause, Dresden. Ger. Pat. 311,071, 27.9.17.

HYDROXYTRIMETHYLENEGLYCINE of the formula $\text{CH}(\text{OH})(\text{CH}_2\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H})_2$, an amorphous yellow powder of m. pt. 73° C. (with decomposition) is ob-

tained by the interaction of glycine and formaldehyde in aqueous methyl alcoholic solution at 40° C.; if the glycine is replaced by its salts, e.g., of calcium or barium, the corresponding salts of hydroxytrimethyleneglycine are formed. The product arising from the reaction $2\text{NH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H} + 4\text{CH}_2\text{O} = \text{C}_6\text{H}_{12}\text{O}_6\text{N}_2 + \text{H}\cdot\text{CO}_2\text{H} + \text{H}_2\text{O}$, is isolated by evaporation of the solution under reduced pressure, or, in case of the salts, by precipitation by the addition of a suitable organic liquid. Hydroxytrimethyleneglycine and its salts possess powerful germicidal properties, but are innocuous to higher organisms.—D. F. T.

Sulphite-cellulose waste liquors; Extraction of a neutral saponin from —. Chem. Fabr. L. Meyer, Mainz. Ger. Pat. 311,139, 7.8.17.

THE saponin is separated from the waste liquor by the usual methods for saponin precipitation or by acidifying with hydrochloric acid or other mineral acid and adding a concentrated saline solution, e.g. of common salt; the saponin is removed by filtration, washed with a solution of common salt, and dried.—D. F. T.

Sweetening agents. Ger. Pat. 311,213. See III.

Chlorination products of propylene; Process of producing —. E. C. R. Marks, London. From Union Carbide Co., New York. Eng. Pat. 137,247, 2.7.19. (Appl. 16,489/19.)

SEE U.S. Pat. 1,315,547 of 1919; this J., 1919, 848 A.

Acid anhydrides and chlorides; Manufacture of organic —. T. H. Durrans, Oxford, Assignor to A. Boake, Roberts and Co., Ltd., London. U.S. Pat. 1,326,040, 23.12.19. Appl., 10.7.18.

SEE Eng. Pat. 130,399 of 1918; this J., 1919, 739 A.

XXII.—EXPLOSIVES; MATCHES.

Nitrogen; Estimation of — in celluloid and explosives by means of the nitrometer. P. Nicolardot and H. Vourloud. Chim. et Ind., 1919, 2, 1317–1320.

ESTIMATIONS of nitrogen in celluloid and explosives by the nitrometer usually give too low results. It is found that the camphor present reacts with the nitrocellulose in presence of sulphuric acid, and it is advisable therefore to carry out the estimation after precipitating the nitrocellulose from an acetone solution of celluloid by means of benzene, which retains the camphor in solution. Diphenylamine, present as a stabiliser, also causes erroneous results, the nitrogen figure being 0.7% too low.—W. J. W.

Nitro-derivatives of diphenylamine. Van Duin and Van Lennep. See III.

Replacing sulphonic groups by nitro groups. Datta and Varma. See XX.

PATENTS.

Nitro-derivatives of tetrahydronaphthalene and its homologues; Manufacture of —. Tetralin Ges.m.b.H., Berlin. Ger. Pat. 299,014, 17.3.16.

By nitrating tetrahydronaphthalene or its homologues with mixed acid or other nitrating mixtures containing not more than 25% of water, and preventing the temperature of the mixture from rising above 50° C. during the earlier stages of nitration, oxidation and formation of resinous products are almost completely avoided. A mixture of α - and β -nitrotetrahydronaphthalene is obtained by nitrating tetrahydronaphthalene with mixed acid or by the action of nitric acid of sp. gr. 1.47 on the

tetrahydro-compound dissolved in acetic anhydride, a mixture of acetic anhydride and acetic acid, or other indifferent solvent. It is a yellow oil, b. pt. 121° – 128° C. at 0.17 mm. By nitrating with a mixture of 160 parts of nitric acid of sp. gr. 1.17 and 200 parts of sulphuric acid monohydrate, 1,3-dinitrotetrahydronaphthalene is obtained. It forms yellow crystals, m. pt. 71° – 72° C., slightly soluble in alcohol and ether, and may be used in admixture with potassium chlorate, ammonium nitrate, or the like for the preparation of explosives. By further nitration of the dinitro-compound with a mixture of nitric acid and oleum a trinitro-derivative, yellowish-white crystals, m. pt. 80° – 81° C., is obtained.

Incendiary mass. A. Chanard, Rueil, France. U.S. Pat. 1,325,618, 23.12.19. Appl. 15.7.18.

SEE Eng. Pat. 131,641 of 1918; this J., 1919, 796 A.

XXIII.—ANALYSIS.

Lead; Use of — as a substitute for platinum. C. Hütter. Z. angew. Chem., 1919, 32, 380.

BASINS made of soft lead may be used instead of platinum basins for certain quantitative analyses. For example, they may be used for the determination of silicon, aluminium, sodium, and potassium in chrome ironstone, the mineral being decomposed on the water-bath by means of sulphuric acid, any change in the nature of the oxidation products present being prevented by introducing a current of carbon dioxide by means of a porcelain tube inserted into a hole in the cover of the basin. The lead sulphate produced may be separated without interfering with the further course of the analysis. —C. A. M.

Melting point methods at high temperatures. I. L. I. Dana and P. D. Foote. Chem. and Met. Eng., 1920, 22, 23–24.

THE authors deal with the determination of melting points by means of electrical pyrometers, and the primary standardisation of thermo-couples. It is impossible to obtain satisfactory freezing point curves with certain materials, e.g., silicates, on account of extremely slow crystallisation, and the melting point curve, although often poorly defined, must be employed. The differential method of measurement shows much greater sensitiveness to small thermal changes than the simple time-temperature curve. —C. A. K.

Rectification column; Glass — for the rectification of liquid mixtures and the recovery of volatile solvents. W. Elsner. Chem.-Zeit., 1920, 44, 11–12.

THE apparatus, which is constructed entirely of glass, consists of a vertical column, 50 mm. in diameter, and filled with ground or etched glass balls; the lower layers are formed of large balls, above these are layers of medium-sized balls, whilst the upper layers consist of small balls. A dephlegmator is fitted at the top of the column and is provided with a water jacket supplied from a constant-level reservoir. A still-head fits into the top of the dephlegmator and carries a thermometer and a side tube connected to a condenser. Ground-in joints connect the different parts of the apparatus. —W. P. S.

Indicator papers. D. J. de Jong. Pharm. Weekblad, 1919, 56, 465–467.

A DROP of acid placed on ordinary filter paper and treated with methyl orange shows only a weak reaction in the immediate neighbourhood of the drop, and beyond this is a neutral area or "water-ring." By preliminary treatment of the paper with

hydrochloric acid, followed by washing and drying, it becomes saturated with hydrogen ions and absorption of the indicator is prevented. The reaction thereby becomes more sensitive and the whole of the moistened area becomes coloured. Addition of a few drops of hydrochloric acid to methylene blue increases its sensitiveness for the same reason. —W. J. W.

Congorubin; Colour change of — under the influence of reactions and neutral salt action. H. Lüers. Kolloid-Zeits., 1920, 26, 15–20.

IN the presence of hydrogen ions at a concentration $5.5 \times 10^{-2} N$ congorubin changes from red to blue instantaneously, but with decreasing hydrogen ion concentration the rate of change decreases, and at $6.8 \times 10^{-4} N$ practically does not take place. In the presence of neutral salts (KCl) the rate of change is increased about 70 times, so that the presence of neutral salts increases the sensitiveness of the indicator to hydrogen ions by about this amount. In the presence of hydroxyl ions neutral salts decrease the sensitiveness of the indicator until with a concentration of $10^{-2} N$ hydroxyl ions the change does not take place. —J. F. S.

Electrometric titration. J. Pinkhof. Pharm. Weekblad, 1919, 56, 1218–1234.

A COMPREHENSIVE description of the potential method of titration. The apparatus and mode of procedure are described and the theoretical considerations involved are discussed. Details are given of special applications of the method to the estimation of halogens in presence of each other and of heavy metals by means of sodium sulphide; titration of bases using the mercury electrode; determination of the hydrogen ion concentration of liquids by means of the hydrogen electrode; titrations by means of the oxidation potential. A difference in potential of 1 millivolt is easily detected by a capillary electrometer. —W. J. W.

Electrometric titrations. J. Pinkhof. Chem. Weekblad, 1919, 16, 1163–1167.

THE suitability of various constant electrodes for specific cases of electrometric titration is discussed. These include titrations of halogens, of heavy metals with sodium sulphide, and of bases.

—W. J. W.

Hydrogen-ion concentration; Determination of —. J. Pinkhof. Chem. Weekblad, 1919, 16, 1168–1172.

THE author outlines a method for determination of the hydrogen-ion concentration and describes a suitable apparatus for the purpose. The best electrode was found to be a cadmium-amalgam electrode in solutions of cadmium of various concentrations. —W. J. W.

Acids; Iodometric estimation of —. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 53–68.

THE iodometric method gives excellent results with strong acids, especially if these are diluted and the reagents allowed to stand for ten minutes before titrating. Accurate results are obtained with organic hydroxy-acids after addition of a salt of calcium, magnesium, or zinc. The method is unsuitable for phosphoric acid or weak organic acids not containing a hydroxy group, except formic acid. —W. J. W.

Carbon dioxide; Apparatus for the determination of small quantities of — by displacing it from liquids by a rapid current of air at ordinary temperature and pressure. A. Constantino. Atti R. Accad. Lincei, 1919, [v.], 28, ii., 118–121.

IN the apparatus described purified air is circulated repeatedly through a closed system by means of a

rotary mineral oil pump. The air passes first through the liquid, acidified if necessary, containing the carbon dioxide and then through a definite volume of standard baryta solution, which is subsequently titrated with acid in presence of phenolphthalein. The whole estimation occupies about 45 minutes. Test experiments with sodium carbonate solutions containing 6.4–21 mgrms. of carbon dioxide show that the method yields accurate results.—T. H. P.

Carbon dioxide and water; Micro-analytical determination of — in minerals. G. K. Almström. J. prakt. Chem., 1919, 99, 312–316.

THE author has successfully adapted Pregl's micro-analytical method for the elementary analysis of organic compounds to the determination of carbon dioxide in minerals, using vanadium pentoxide (dried at 300° C.) in place of potassium bichromate; the latter gives low results due to incomplete decomposition of the mineral. Owing to the difficulty of completely removing moisture from the vanadium pentoxide and the relatively large proportion employed (0.2–0.3 gm. per 20–30 mgrms. of mineral), high results are obtained for water. Penfield's method (Amer. J. Sci., 1894, [3], 48, 31) was, however, found suitable for micro-analysis, and gave satisfactory results.—J. K.

I.—GENERAL; PLANT; MACHINERY.

Gases; Absorption of — in spray systems and towers. E. M. Baker. Chem. and Met. Eng., 1920, 22, 122—124.

CONSIDERING the general case of the absorption of a gas in a liquid which exerts an appreciable vapour pressure due to the dissolved gas, the theoretical absorption (K) under given conditions may be increased by applying any means which increases the partial pressure of gas in the mixture, or reduces the vapour pressure of the gas in the liquid. The rate of absorption depends on the difference (D) between the partial and vapour pressures, on the degree of contact (I) between the liquid and the gas mixture, and the time of contact (T). The actual absorption (P) for any gas and liquid may be represented: $P = CKDIT$, C being a constant. K and D will be fixed generally by plant conditions, and I and T by the design and operation of the plant as a whole. The formula is not capable of direct mathematical application, but may be useful in the comparison of various systems of absorption.—C. A. K.

PATENTS.

Shaft furnaces and gas producers. E. F. Chaudière, Paris. Eng. Pat. 137,168, 3.3.19. (Appl. 5220/19.)

THE furnace is of the type used in the production of lime and cement, for roasting and calcining ores, and for blast furnaces, gas producers, etc. The vertical furnace is provided with a central vertical core consisting of two concentric cast-iron columns connected by radial ribs, the lower part of the core being surrounded by another hollow column, and the upper part by refractory masonry containing recuperating flues. A fan situated at the bottom of the central core exhausts the combustion products and thus causes a flow of air upward through the central column, where it is preheated, and air is also drawn upwards through some of the surrounding passages. Part of the latter air current passes into the furnace through openings about the middle of its height, and the remainder continues upward to meet the central current at the top. The hot air then passes downward through other flues in the core, and is also discharged into the furnace about the middle of its height. A strongly heated zone is thus formed in the furnace, and the position of this zone is stabilised. Air is also admitted to the lower part of the furnace through additional flues in the central core, and preheating flues are also provided in the outer casing of the furnace.—W. F. F.

Drying apparatus. A. Nordstrom and C. A. Oberg, Buenos Aires, Argentina. U.S. Pat. 1,326,525, 30.12.19. Appl., 23.10.17.

A HORIZONTAL cylindrical casing rotating on its axis is provided with several inner concentric cylindrical partitions attached to the two end walls alternately so as to form a continuous passage. Longitudinal ribs may be provided on the inner walls of some of the partitions, and also helical ribs of opposite thread in every two successive drums. The material is fed into the innermost compartment which is exhausted, and is discharged at the outer periphery of the casing to an elevator formed integrally with the casing. The air between the various partitions is heated by heating coils.—W. F. F.

Grinding mills of the rotating disc type. F. Corbett, Rhyl, Wales. Eng. Pat. 137,231, 5.6.19. (Appl. 14,249/19.)

THE object is to secure the accurate setting of the

fixed disc in a grinding mill having a rotating disc coacting with a fixed disc. The driving shaft, 3, is carried in bearings, 2, supported by the bed-

plate, 1. The bedplate is also formed with a socket, 11, to receive the back plate, 10a, of the casing, 10, which supports the fixed disc, 12; the socket is bored out at the same time as the bearings, 5, to ensure concentricity. The face, 17, of the casing back, 10a, is machined true with the cylindrical part, 13, so that when the fixed disc, 12, is secured to it the grinding face will be accurately transverse to the shaft, 3. The rotating disc, 20, is fixed to a chuck, 21, which is keyed to the shaft, 3, the chuck, 21, being bored and faced at the same operation.—W. F. F.

Oil emulsions; Apparatus for the treatment of —. C. W. McKibben, Houston, Tex. U.S. Pat. 1,327,835, 13.1.20. Appl., 18.12.18.

THE separation of water from an emulsion with oil is effected by making the mixture follow a tortuous path between two vertical concentric pipes in a tank; the space between the pipes is occupied by a series of discs with openings near their axes and their peripheries alternately; the inner pipe may be heated.—D. F. T.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Asphalt and coal; Origin of — J. Marcusson.
Chem.-Zeit., 1920, 44, 43–44.

NATURAL asphalts are derived from petroleum by evaporation of the lighter fractions, and by the partial polymerisation and condensation, or oxidation, or decomposition by sulphur and sulphur compounds, of the residual hydrocarbons. Polynaphthenic acids form a link between petroleum and asphalts, and are distinguished from naphthenic acids by the insolubility of the copper salt in hydrocarbons. They are brownish-black compounds of a consistence varying from that of thick oils to that of resins. They are soluble in alcohol, glacial acetic acid, and chloroform, but insoluble in benzene. Their specific gravity is above 1.0. The alkali salts are soluble in water; those of the alkaline-earths and heavy metals are insoluble. Their iodine value is approximately 20. They are probably formed by combination of two molecules of a high-boiling petroleum hydrocarbon. On heating they are converted into anhydrides; at higher temperatures neutral, unsaponifiable asphalts are produced. Humic acid is the corresponding link between coal and vegetation. Its constitution is doubtful, although it certainly contains a furfuran group. It may be regarded as a polymerised or condensation form of mucin. The processes by which petroleum and cellulose are respectively converted into asphalt and coal are analogous.

—W. J. W.

Coke; Principal innovations in the recovery of by-products in the manufacture of metallurgical — C. Berthelot. Bull. Soc. Ind. Nord, 1919, 46, 87–192.

THE author reviews the various systems of by-product recovery, and indicates those which seem to him to be the most practicable and the various modifications which he has introduced. Descriptions are given of hot condensation systems (Solvay, Bawag, Carrès, and Otto), cold systems (Klönne, St.-Claire Deville), condensation in horizontal tubes, and condensation in cylindrical condensers. Of all these systems, that of St.-Claire Deville alone satisfies the conditions necessary to obtain a suitable absorption of the naphthalene and ammonium salts, whilst giving the best possible yield of ammonia and benzol, because the gas and the condensation products are cooled simultaneously. In hot condensation systems the gas is not completely stripped of naphthalene, and 3–5% of ammonium salts is lost in the tar, from which it is difficult to recover them. The tar is washed with water in a column; if this is not done the ammonium chloride, which constitutes 60–80% of the salts, dissociates, and the hydrochloric acid thus produced corrodes the tar distilling plant. Xylene, cumene, and phenol are lost in the liquors, which condense when the gas cools after its passage through the saturator. The author compares the value of turbo-, Roots, and Beale exhausters, stating that turbo-exhausters are only useful for purified gas, whilst Roots exhausters are easily worn out by the impurities in the gas. Beale exhausters are recommended as being very robust, and capable of being employed for even 150 cm. of water pressure. Two regulators are recommended for controlling the suction of the gas, *viz.*, that made by the Compagnie pour la Fabrication des Compteurs et Matériel d'Usines à Gaz, and the Kress regulator. In the recovery of benzol the Zschokke system is largely used in France, but the author

prefers splash washers, which give a yield of 75% (compared with 70% with the Zschokke system). In the recovery of ammonia the losses in the plant per metric ton are given as:—In evaporation, 40 grms.; in washing, 9 grms.; in distillation, 12 grms.—total, 61 grms., equivalent to 240 grms. of ammonium sulphate. In the manufacture of the sulphate a special comparison of the Feld and Burkheiser processes is made as regards the simultaneous recovery of ammonia and sulphur, and an examination of the possibility of transforming cyanogen into ammonia by oxidation. The Feld system consumes less water but has the higher steam consumption. The recovery of fixed ammonium salts is complete in the Burkheiser system, but loss occurs in the Feld system. It is difficult to obtain a pure sulphate in either plant, and the cost of installation does not compare favourably with the older systems. Attention is drawn to results obtained at the experimental plant of the Association of German Gas Manufacturers at Karlsruhe. Five German coals were tested, and the mean result showed that 8.02% of the ammonia was lost in the tar. To remedy this a process has been devised (see Fr. Pat. 439,509; this J., 1912, 711) according to which the ammonium chloride is condensed in solid form before the gas is scrubbed. A comparison of the German and French (Mallet) systems for the recovery of benzol from the wash oils shows that the French system is more economical than the German one in the ratio of 1.0 to 1.2 in heat expended.—A. G.

[Gas] retort linings. P. M. Grempe. J. Gasbeleucht., 1919, 62, 734–735.

METHODS of lining gas retorts etc. with a coating of carborundum are described. Carborundum powder is used, and is made into a paste with water-glass or fireclay and water. The proportions used are 75 parts of carborundum and 25 parts of water-glass or 85 parts of carborundum and 15 parts of clay by weight. The whole must be well mixed and kept agitated during application. A deposit of $\frac{1}{2}$ mm. thickness is sufficient for most purposes, corresponding to about 1200 grms. of carborundum per sq. m. of surface. The deposit is allowed to stand for 24 hours and then slowly heated. These carborundum linings have worked successfully in many types of retorts and furnaces with coal, coke, or gas firing. The mixture may also be used for repairing flaws in the retorts.—W. P.

Lignite; Carbonisation of — R. Geipert. J. Gasbeleucht., 1919, 62, 742–744.

A DESCRIPTION is given of the carbonisation of lignite at the Mariendorf gasworks. The lignite was delivered in the form of rough lignite, small lignite, and briquettes, the respective calorific values being 2700 cal., 3500 cal., and 4900 cal. A large reduction in volume was observed on carbonisation, the height of coke in a fully charged vertical retort 5 m. high falling to 305 cm. in the case of the small lignite, and to 290 cm. with the briquettes. The resulting coke was very fine. In the former case the coke burnt rapidly on being discharged from the retort. Somewhat better cokes were obtained by carbonising mixtures of the briquettes with pit coal. A comparison of the yields and costs of the carbonisation of pit coal and lignite shows the latter to be uneconomical.—W. P.

Water-gas production in horizontal retorts and its economy. E. Goffin. J. Gasbeleucht., 1919, 62, 729–731. (See this J., 1919, 523 A.)

FURTHER particulars are given of the steaming of horizontal gas retorts at the Heddernheim gasworks, and the advantages of this system over that of the separate production of water-gas are discussed. The coke used for the production of 100 cub. m. of water-gas was 54.06 kilos. A greater

water supply was required in the coolers to cool the mixed gas on account of the undecomposed steam carried over. The heat units supplied in the gas from 3 settings in 1 hour was 2,463,900 cals. with steaming and 2,244,600 cals. without steaming. The necessity for clearing the ascension pipe, and cleaning the receivers and retorts was lessened, and the life of the retorts thereby improved. The costs of production are also examined.—W. P.

Water-gas sampling device. R. A. Carter. Amer. Gas Assoc. Gas J., 1920, 149, 196—197.

THE apparatus described is designed to determine automatically the quantity of gas made during a run, and to collect a representative sample of the gas, not at a uniform rate, but at a rate dependent upon the rate of production. A purified stream of gas is passed at a uniform pressure through an adjustable orifice, the opening of which is controlled by a diaphragm which, in its turn, is actuated by the drop in pressure across a fixed resistance. This resistance is the wash-box, and the drop in pressure across it is proportional to the rate of flow or production of the gas. The sampling device consists primarily of a pressure-regulating governor, a differential pressure governor (a diaphragm directly connected to an adjustable orifice), a condenser, a purifier, and a holder to collect the sample. The holder is calibrated to show the volume of gas made.—W. P.

Flame; Propagation of — in mixtures of methane and air. Part I. Horizontal propagation. W. Mason and R. V. Wheeler. Chem. Soc. Trans., 1920, 117, 36—47.

A DESCRIPTION is given of the phases, other than the uniform movement, during the horizontal propagation of flame in mixtures of methane and air. The duration of the uniform movement of flame, set up initially when a mixture is ignited at the open end of a horizontal glass tube closed at the other, is controlled by the factors which influence the establishment of resonance in the column of gases in the tube: speed of flame, and length, diameter, and uniformity of bore of the tube. With mixtures containing between 10 and 10.5% of methane, and with a brass tube 210 cm. long and 5 cm. in diameter, the speed of flame during the uniform movement was 90 cm. per second over a distance of 80 cm. Faint undulations in the flame front appeared after the flame had travelled 32 cm., but these did not affect the mean speed of the flame. The amplitude of the vibrations increased gradually at first and then more rapidly, the mean speed of the flame falling to 64 cm. per second. Eventually the "vibratory movement," which owes its origin to an undulation of abnormal amplitude, was established. During the forward motion of the flame during the vibratory movement a speed of 2430 cm. per sec. was attained, but the maximum mean speed of flame over the section of the tube photographed was 278 cm. per sec. When ignition takes place at the closed end of a horizontal tube, open at the other, no uniform movement takes place, but the speed of the flame increases rapidly as it travels towards the open end. The speed of flame in some of the mixtures reached 29 m. per sec. over the last half metre of the tube. In longer and wider tubes the flame was extinguished during violent vibrations after the flame had travelled 10 m. The extinction was caused by the contraction of the gases behind the flame dragging the flame back and mixing unburnt gas with the products of combustion. With the tube opened at both ends no such extinction was noted, the flame accelerating in speed as it passed along the tube. This is the condition which would lead to the most disastrous results in industry, for, although the initial speed of the flame is not then so great as when ignition is at a closed end, continued propagation is assured,

and there may be developed momentarily during the vibratory movement velocities and pressures as great as any produced throughout the life of a flame started at a closed end.—W. P.

Flame; Propagation of — in complex gaseous mixtures. Part IV. The uniform movement of flame in mixtures of methane, oxygen, and nitrogen. "Maximum-speed mixtures" of methane and hydrogen in air. W. Payman. Chem. Soc. Trans., 1920, 117, 48—58. (See also this J., 1920, 94 A, 95 A).

THE mixture of hydrogen and air for complete combustion, that is, the mixture having the greatest heat of combustion, contains 29.6% of hydrogen, but the mixture in which the speed of the uniform movement of flame is the greatest contains 38%. A similar "displacement" of the maximum-speed mixtures is observed with all inflammable gases when mixed with air, including gases, such as carbon monoxide, the thermal conductivities of which are less than that of air. The speed of propagation of flame during the uniform movement depends mainly upon the rate of conduction of heat from layer to layer of the mixture, which in turn varies according to the difference in temperature of the burning and the unburnt gases and to their thermal conductivities, and upon the rate of reaction between the combining gases, which for a given combustible gas will vary with the composition of the mixtures, according to the usual laws of mass action and with the temperature of the reaction. The rate of reaction appears to be the determining factor in the position of the maximum-speed mixture, the displacement being shown to be due to the influence of mass action upon the rate, this not having its maximum effect in the mixture with the greatest calorific value. The displacement is in the opposite direction, that is, with excess oxygen, when oxygen burns in an "atmosphere" or constant composition mixture of nitrogen with a combustible gas. Further, the maximum-speed is that of the mixture containing the gases in combining proportions when hydrogen or methane burns in pure oxygen, since in this mixture both the effect of temperature and of mass action have their greatest value. The speed of the uniform movement of flame has been determined in mixtures of methane with a number of different atmospheres of nitrogen and oxygen containing more oxygen than air and with pure oxygen. The maximum speeds of the uniform movement of flame were 55 m. per sec. for the mixture $\text{CH}_4 + 2\text{O}_2$ and 66 m. per sec. for the mixture $2\text{H}_2 + \text{O}_2$. The uniform movement gives place to the detonation-wave after quite a short distance of travel of the flame in the fastest mixtures, but with the detonation-wave the maximum-speeds are obtained with mixtures containing excess of methane or hydrogen.—W. P.

Oil shales; Retort plant for the distillation of —. L. Simpson. Chem. and Met. Eng., 1920, 22, 71—72. (See this J., 1920, 147 A.)

CERTAIN qualities of shale yield by-products, the recovery of which from the spent shale is profitable, varying either according to their quantity or local conditions, even after the maximum oil yield has been secured. The temperature distribution does not render the Scotch dual retort satisfactory in this respect. It is suggested that shale should be distilled in a "single" retort giving a satisfactory yield of oil, and that the spent material should then be heated directly in a horizontal rotary kiln. The fixed carbon in certain shales is sufficient to produce, on combustion, the lower limit of temperature (1150° C.) required for the maximum recovery of ammonia. Fine grinding of the spent shale would assist in the production of ammonia,

and the recovery of potash becomes feasible if the final temperature in the kiln is increased.—C. A. K.

Asphaltic base acid sludge obtained in refining petroleum and shale oils; Utilisation of —. C. Baskerville. J. Ind. Eng. Chem., 1920, 12, 30—31.

THE "acid sludge," obtained in refining petroleum and shale oils with sulphuric acid, is usually heated, by means of live steam, with strong sulphuric acid to separate oil capable of being refined and to carbonise the rest of the material. The mass, which after washing still contains 3—15% of free sulphuric acid, is then burned with coal. If the treatment with sulphuric acid is stopped prior to the carbonisation of the asphaltic material, the mass separates into three layers, viz., oil, asphaltic sludge, and excess of sulphuric acid. The sludge, containing 15—25% sulphuric acid, is washed once with five times its quantity of water, treated with a slight excess of freshly slaked lime, and kneaded in a mill. If sufficient heat has not been generated to render the mass fluid the mixture is heated to about 220° C. and then run into suitable containers. Finely divided limestone may be substituted for the lime. The asphaltic material is incorporated with 10—40% of calcium sulphate. It adheres well to masonry, wood, metal, etc., forming a waterproof coating, and can be mixed with rosin etc. If desired, the asphaltic substances may be extracted by the usual solvents.—C. A. M.

Coal pyrites. Yancey. See VII.

Gas producers. Atkinson. See VIII.

PATENTS.

Powdered fuel; Combustion of —. J. S. Atkinson, and The Powdered Fuel Plant Co., Ltd., London. Eng. Pat. 137,450, 17.4.19. (Appl. 9893/19.)

THE powdered fuel is fed into the combustion chamber in intimate mixture with air by means of a fan, the admission of air being governed by suitable means, such as a hit-and-miss device, in accordance with the load on the plant and the amount of fuel being supplied. A secondary supply of air direct to the combustion chamber may also be used and governed in the same manner.—W. P.

Inert gases; Apparatus for preparation of —. E. E. Molas, Paris. U.S. Pat. 1,327,769, 13.1.20. Appl., 2.7.18.

THE burnt gases from an internal combustion engine are withdrawn through a pipe with an adjustable intake valve. A check valve in the same pipe is actuated by the force of the explosion. The storage tank contains a liquid having a basic character.—W. P.

Petroleum and other hydrocarbons; Fractional distillation of crude —. A. F. G. C. P. J. von Groeling, Assignor to Atlas Process Co., Inc., New York. U.S. Pat. 1,327,184, 6.1.20. Appl., 22.4.16.

EACH of a number of stills is provided with a separate condenser and receiver, and each receiver is attached to an apparatus for creating a high vacuum, which is automatically maintained at a constant degree, in the stills, condensers, and receivers. The means for heating the stills can be controlled so as to vary the temperature of distillation in the different stills.—L. A. C.

Evaporator [for distilling mineral oils]. W. Meischke-Smith, San Francisco, Cal., Assignor to Shell Co. of California. U.S. Pat. 1,327,247, 6.1.20. Appl., 26.3.18.

OIL is delivered as a thin film on to the inner surface of the side walls of a still, shaped in the form

of an inverted frustum of a cone, by means of a conduit enclosing the upper edge of the side walls and having an open circular slit on the inside of the wall. Means are provided for supplying oil to the conduit, for removing vapour from the still, and for drawing off residual oil from the bottom of the still.—L. A. C.

Liquids, fluids, and oils; Process for the conversion of — [to lower boiling oils]. J. H. Adams, Brooklyn, N.Y., Assignor to The Texas Co., Houston, Tex. U.S. Pat. 1,327,263, 6.1.20. Appl., 30.3.11. Renewed 11.4.19.

OILS to be converted into lower boiling products are heated, in a liquid form, in a chamber to a cracking temperature, and the vapour pressure generated in the chamber is maintained on the oils. The vapours are led to a condenser through connections, all of which are in open communication to ensure a uniform pressure from the chamber through the condenser. The lower boiling oils are withdrawn from the condenser.—L. A. C.

Bituminous matter; Process of recovering — from shale. H. D. Ryan, Boulder, Colo., Assignor to National Oil Machinery Corporation, New York. U.S. Pat. 1,327,572, 6.1.20. Appl., 28.3.18.

SOLIDS (shale) containing bitumen are digested with a heavy oil at a temperature high enough to liquefy heavy hydrocarbons present in the shale, but insufficiently high to distil heavy fractions of oil.—L. A. C.

Lubricating oils; Production of — from asphaltic materials. Deutsche Erdöl-Akt.-Ges., Berlin, F. Seidenschmür, Charlottenburg, and C. Köttnitz, Berlin-Lichterfelde. Ger. Pat. 305,105, 4.3.16.

ASPHALTIC materials are distilled with steam in rarefied air or in a vacuum. The oils thus obtained are highly viscous and, after treatment with steam to remove the lighter fractions, have a high flash point. About 60% of high quality cylinder oil may be produced. The residual coke is free from oil and very little gas is evolved in the process.—W. J. W.

Lubricating oils; Process for preparation of highly viscous and combustible — from bituminous materials, especially lignite tar. Deutsche Erdöl-Akt.-Ges., Berlin, F. Seidenschmür, Charlottenburg, and C. Koettnitz, Berlin-Lichterfelde. Ger. Pat. 307,166, 7.11.16.

LIGNITE is gasified in producers, the tar recovered being distilled with superheated steam, with or without vacuum (see preceding abstract). Tar obtained from lignite briquettes yielded 20% of machine oil (viscosity: 6.2 at 50° C.; flash point: 188° C.), and 10% of spindle-oil (viscosity: 4 at 20° C.; flash point: 150° C.); the yield of paraffin was not diminished.—W. J. W.

Fire grates for combustion of small or powdered fuel. A. E. Davis, Birmingham. Eng. Pat. 137,375. (Appls. 1040, 15.1, and 1931, 27.1.19.)

Gas retorts; Apparatus for maintaining predetermined pressure conditions in —. A. A. Macintosh, St. Kilda, and W. H. Hunt, Melbourne, Victoria. U.S. Pat. 1,329,129, 27.1.20. Appl., 2.4.17.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Electric lamp; A new —. F. Schröter. Elektro-techn. Zeits., 1919, 186. Chem.-Zeit., 1919, 45. Rep., 303.

A LARGE cathode and smaller anode are arranged within a pear-shaped globe containing a mixture of neon and helium at a pressure of 8–10 mm. A discharge is produced between the electrodes employing 220 volts. Where alternating current is employed, the electrodes are of the same size and are arranged symmetrically. Iron, aluminium, or potassium can be used as cathode. Iron possesses certain advantages. The lamp is designed for an energy consumption of from 1 to 5 watts at 220 volts. The intrinsic brilliance of the lamp is about 0.1 Hefner candle per sq. cm. Its life is determined by the sputtering of the cathode. A number of directions in which the lamp may be employed is indicated.—J. S. G. T.

PATENTS.

Heating of vessels; Process for indirect — [using esters of phthalic acid as heat-transmitting medium]. Akt.-Ges. f. Anilin - Fabrikation, Berlin-Treptow. Ger. Pat. 302,581, 11.3.17.

NEUTRAL esters of phthalic acid, which are mobile liquids and can therefore be easily poured, may be used as a heat-transmitting medium. They are stable and non-inflammable, with a high boiling point (280°–290°C.) and a flash-point above 160°C. —W. J. W.

Electrode; Arc-lamp —. W. R. Mott, Lakewood, Ohio, Assignor to National Carbon Co., Inc. U.S. Pat. 1,326,605, 30.12.19. Appl., 23.1.19.

AN arc-lamp electrode contains a combination of potassium silicate and boric oxide, in a form less hygroscopic than either of the materials alone. —B. N.

Electric arc-lamps; Diminution in the energy expenditure per candle power of —. O. Lummer, Breslau. Ger. Pat. 303,262, 26.5.14.

THE carbons are impregnated with suitable substances, such as alkaline-earth fluorides, and are employed to afford a flaming arc which is operated intermittently. Under such conditions the area of the positive crater is reduced and the efficiency of the arc is increased.—J. S. G. T.

Direct current arcs; Arrangement of —. O. Lummer, Breslau, G. R. Mylo, Charlottenburg, and Rütgerswerke A.-G., Berlin. Ger. Pat. 304,221, 28.7.15.

A NUMBER of arcs are struck between a number of electrodes of like polarity surrounding a central electrode of opposite polarity. The central electrode is constituted of a number of parallel sections capable of being separately adjusted. The

arrangement permits of the attainment of a higher temperature than usual. An enhanced illuminating effect is thereby obtained from vapours introduced into the arcs. It is also possible to impregnate the negative electrode with salts which hitherto could either not be employed at all or at most only in very small quantities.—J. S. G. T.

Arc lamp having more than one arc. O. Lummer, Breslau, G. R. Mylo, Charlottenburg, and Rütgerswerke A.-G., Abt. Planawerke, Berlin. Ger. Pat. 303,355, 19.3.16.

THE inner electrode of a multiple arc (see Ger. Pat. 304,223 above) is composed of sections which may be impregnated with different salts. Such sections may be in intimate contact with one another or may be separated by a good thermal conductor. For example, the electrode may be constituted of a solid portion together with a second portion perforated by channels or wicks, these being impregnated with salts, which are entirely absent from or present only to a small extent in the solid portion of the electrode. The two halves may if desired be provided with channels having similar or different characteristics. The device enables the temperature of the negative electrode to equal that existing in the positive crater.—J. S. G. T.

Arc electrodes for the production of short wave-length radiation. Siemens-Schuckertwerke G. m. b. H., Siemensstadt. Ger. Pat. 315,217, 8.3.18.

CERTAIN metals or compounds thereof, the radiations of which show maxima corresponding approximately in wave length with the minima in the radiation of the iron arc, are incorporated along with iron or compounds thereof in the electrodes with a view to enriching the spectrum of the arc in the region of short wave lengths included between 400 μ and 250 μ . Titaniferous iron, zinc, and magnesium or their compounds may be used either singly or in conjunction for this purpose. Cryolite, zinc borate, and potassium magnesium fluoride may be incorporated along with titaniferous iron. The arc is struck in an atmosphere containing very little oxygen.—J. S. G. T.

Electrodes for high vacuum discharge-tubes. C. H. F. Müller, Hamburg. Ger. Pat. 305,521, 1.11.17.

THE electrodes are composed either wholly or in part of chemically pure iron, more particularly of electrolytic iron.—J. S. G. T.

Röntgen-ray tube. Siemens und Halske A.-G., Siemensstadt. Ger. Pat. 311,941, 6.1.18.

SUITABLE elements or their oxides are superposed upon the anticathode in a number of thin layers penetrable by the electrons, and preferably in the form of intersecting lines in close juxtaposition forming a kind of grating. Such coatings serve to increase the hardness of the X-rays. As an example, a platinum anticathode may be coated with one or more of the elements, polonium, thorium, and uranium.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Coal tar; Resinous constituents of —. J. Marcussou. Z. angew. Chem., 1919, 32, 345–346.

FINELY-POWDERED coal yielded on extraction with pyridine a product which when sulphonated was completely insoluble in water, whereas tar resins form soluble sulpho acids. Hence these resins are not present as such in the original coal. Experiments indicated that they are produced by an oxidation process. The three tar resins, previously de-

scribed (this J., 1918, 403 A), were artificially prepared by blowing air into coal tar oil of high b. pt. at about 120° C. The product, when treated with acetone, yielded an insoluble deposit; the filtrate from this was freed from solvent, and the residue treated with glacial acetic acid, leaving a black, pitch-like mass which, when digested with acetone, yielded the solid resins. These resins behaved in the same way as those separated from coal tar. They may also be produced by heating the oil for a long time under a reflux condenser. The thickening of tar lubricating oil in technical operations depends mainly on the production of tar resins. According to Ruszig (this J., 1919, 217 A) phenylxanthenes are constituents of tar lubricating oils, but artificially-prepared phenylxanthene did not yield a resin when blown at 120° C., and is therefore not the original substance from which the resins are derived. It is more probable that the resins are derived from unsaturated hydrocarbons, and their formation is analogous to that of asphaltic substances from mineral oils of high b. pt. Their physical and chemical characters are also similar. The tar resins appear to differ essentially from asphaltenes only in aromatic character, and may therefore be regarded as aromatic asphalts.

—C. A. M.

Cresol (cresylic acid); Purified —. H. C. Hamilton. J. Ind. Eng. Chem., 1920, 12, 50—52.

CRUDE cresol is dissolved in a solution of sodium hydroxide of equivalent alkalinity, and sufficient water added to dilute the sodium cresylate to about a 25% solution. The liquid is then boiled or subjected to the action of live steam until all the volatile impurities (pyridine etc.) have been removed, the evaporated water being replaced in order to prevent the solution becoming so concentrated that the cresylate is decomposed and free cresol volatilised. After cooling, any oil upon the surface of the liquid is skimmed off, whilst any naphthalene remaining unvolatilised is removed by filtration or centrifuging. Finally the cresylate is decomposed by the addition of an amount of sulphuric acid equivalent to the alkali originally used, and the separated cresol is redistilled.—C. A. M.

By-product recovery in coke manufacture. Berthelot. See IIa.

PATENTS.

Oils; Process of extracting — from coal-tar. H. H. Comber and J. W. Stalker, Winnipeg, Canada. U.S. Pat. 1,327,271, 6.1.20. Appl., 17.6.18.

COAL-TAR is agitated in the cold with wood alcohol; the upper layer, containing the oils and alcohol, is drained into a vessel containing water, which dissolves the alcohol. The oils are then drawn off from the bottom of the vessel.—L. A. C.

Coal tar and the like; Process for purification of — and simultaneous recovery of high-molecular resinous bases. E. Wirth, Wiesbaden. Ger. Pat. 303,273, 24.2.15.

TAR obtained by dry distillation of bituminous substances is freed from phenols by treatment with an alkaline solution and then treated with dilute, followed by more concentrated mineral acid. As the salts of the resinous bases (constituents of the so-called "acid tar") are soluble in phenol, its initial removal enables the resinous bases to be recovered. The tar may be freed from its more volatile constituents before being subjected to the treatment.—W. J. W.

Tar oils; Process for purification of heavy — and recovery of bases of high boiling point. E. Wirth, Wiesbaden. Ger. Pat. 304,306, 13.2.16. Addition to Ger. Pat. 303,273.

THE process described in the preceding abstract

may be applied to heavy tar oils to recover the bases from them by treatment of the acid solution with alkalis. The acid concentration is kept sufficiently low to prevent separation of resinous substances. The bases are obtained in the form of a viscous oil distilling mainly between 320° and 390° C. The mixture contains acridine and also non-crystallisable bases of the formula $C_{2n+1}H_{n+3}N$, beginning with $C_{13}H_{19}N$. These bases may be utilised for the manufacture of dyes and pharmaceutical preparations.—W. J. W.

Fractional distillation of hydrocarbons. U.S. Pat. 1,327,184. See IIa.

Lubricating oils. Ger. Pat. 307,166. See IIa.

Phthalic esters as heat-transmitting medium. Ger. Pat. 302,581. See IIa.

IV.—COLOURING MATTERS AND DYES.

Diazotisation; The factors of —. E. Tassilly. Bull. Soc. Chim., 1920, 27, 19—33.

Using the spectrophotometric method previously described (this J., 1914, 247), the authors have studied the diazotisation of a number of amines. The reaction is shown to be bimolecular and, in the case of aniline, its velocity is not modified by doubling the acidity of the solution. The diazotisation of sulphanilic acid is much more rapid when the concentration of the reacting solutions is increased, and it is favoured by an excess of sodium nitrite. The stability of diazo compounds with respect to time and temperature may be studied by this method.—W. G.

Mordant dyestuffs; New bases for the preparation of —. H. Bamberger. Z. angew. Chem., 1920, 33, 8.

THE chlorides of *o*-nitrophenol-*p*-sulphonic acid, 6-nitro-*o*-cresol-*p*-sulphonic acid, and 6-nitrosalicyl-*p*-sulphonic acid, obtained by treatment of their potassium salts with chlorosulphonic acid, react quantitatively with aromatic amines, diamines, aminocarboxylic acids, or aminophenols, and with aminosulphonic acids or aminophenolsulphonic acids of the benzene or naphthalene series. By reducing the resulting sulphamino-compounds with sodium sulphide, valuable bases are produced for mono- and di-azo mordant dyestuffs, which give colours ranging from yellow to bluish-violet.—J. K.

PATENTS.

Coal-tar dyes; Production of —. E. D. Kendall, Elizabeth, N.J., Assignor to Haggin Estate, Inc. U.S. Pat. 1,326,665, 30.12.19. Appl., 5.4.18.

DYES are produced from nitrobenzene or its homologues by electrolysis of a mixture of one or more nitro-compounds, acetone, water, and sulphuric acid.—L. L. L.

Dyestuffs and process of making same. A. S. Wheeler, Chapel Hill, N.C. U.S. Pat. 1,327,260, 6.1.20. Appl., 9.12.18.

A SOLUTION of a hydroxynaphthoquinone having less than three hydroxyl groups is treated with a halogen in excess; the halogenated product is then separated and converted into a salt.—L. A. C.

Azo dyes and process of making same. R. Taggesell, Buffalo, N.Y., Assignor to National Aniline and Chemical Co., Inc., New York. U.S. Pat. 1,327,688, 13.1.20. Appl., 6.9.19.

ONE mol. of tetrazotised *m*-toluylenediaminesulphonic acid ($CH_3NH_2 \cdot SO_3H = 1:2:6:4$) is combined with 1 mol. of a *m*-toluylenediaminesulphonic acid, and the product is then combined with a suitable unsulphonated compound.—L. A. C.

Dye. U.S. Pat. 1,326,367. See VI.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Degreasing (scouring) wool and textiles with volatile solvents. H. Hey. J. Soc. Dyers and Col., 1920, 36, 11—16. (See also this J., 1919, 406A.)

THE author describes the degreasing of wool by solvents, giving a list of solvents and the properties of some of them. With "burry" greasy wool, carbonising in the grease is recommended, the grease preserving the wool. The warm material from the drying oven, after carbonising, is degreased by solvents and then the burrs are crushed and shaken out. The acid is then removed by washing with water, followed by soda, and a final washing with soap leaves the wool in good condition for the further operations. The consumption of acid is greater than by the ordinary method of carbonising after scouring, but is compensated for by the better results obtained. Owing to the absence of previous alkali treatment, the wool is finished in a better condition than by the ordinary method. *Sterilising wool.* Very dilute hydrochloric or sulphuric acid solutions are capable of rendering anthrax spores sterile, especially at high temperature. It is proposed to steep the raw greasy wool in a dilute acid bath, to which 1% of formaldehyde is added; after thorough impregnation with the liquid the wool is drained, centrifuged, and dried at a high temperature to sterilise.—L. L. L.

Alder wood; Chemical composition of —. C. G. Schwalbe and E. Becker. Z. angew. Chem., 1920, 33, 14—16.

A DETAILED discussion of the results of analyses of samples from trees of various ages. With increase in age, the proportions of lignin and of pentosan-free cellulose increase, whilst that of acetic acid obtainable by hydrolysis diminishes. Contrary to the view of Pringsheim and Magnus (this J., 1919, 714A), therefore, there is no relation between the proportions of lignin and acetic acid. The heartwood contains more lignin, but less cellulose than the sap wood.—J. K.

PATENTS.

Wool-scouring liquors; Process for treating —. G. Kolsky, New York, Assignor to The Diamond Match Co., Chicago, Ill. U.S. Pat. 1,325,873, 23.12.19. Appl., 24.12.15.

THE grease contained in the scouring liquors is coagulated by means of a soluble derivative of sulphurous acid, the sulphur dioxide of which is in unstable combination, so that on heating with water the compound is decomposed into materials which will readily separate from the liquor, and may be again used for the regeneration of the sulphurous acid derivative. The coagulated grease is separated and refined.—L. L. L.

Drying and carbonising machine [for fibrous materials]. T. Allsop and W. W. Sibson, Assignors to The Philadelphia Drying Machinery Co., Philadelphia, Pa. U.S. Pat. 1,326,161, 30.12.19. Appl., 19.2.19.

A RECTANGULAR casing is divided by horizontal partitions into compartments which are subjected to different heat conditions as required, and each compartment is provided with a horizontal endless band conveyor. The material is fed on to the uppermost conveyor outside the casing, and after passing through the compartment is transferred to the conveyor in the next compartment by means outside the casing, the ends of the conveyors being extended outside the casing for this purpose.

—W. F. F.

Paper or cellulose fabrics; Process for improving —. Exportingenieur für Papier- und Zellstofftechnik G.m.b.H., Berlin-Wilmersdorf. Ger. Pat. 303,861, 30.9.15.

THE fabric, preferably after treatment with a swelling agent, such as caustic soda, ammoniacal copper solution, lactic acid, etc., is subjected to fulling, either dry or damp, in order to compress it. Albumin may be used both as a swelling and a finishing agent, added either after the fulling or after the drying; it is preferable to add to it small quantities of acids or alkalis to increase the swelling effect and the ease of penetration of the albumin into the fibre, and of a hygroscopic substance to reduce the hardness of the fabric. If the fabric is to be exposed to wet conditions a water-repellent substance, such as wool-fat, should be added.—B. V. S.

[Reeds;] Process for obtaining technically valuable products [from —]. Verwertung inländischer Produkte, G.m.b.H., Charlottenburg. Ger. Pat. 304,285, 21.12.16.

THE root stem of the plant (*Arundo phragmites*) is separated by mechanical means, assisted, for instance, by treatment with weak caustic soda solution at 100° C., into a fibrous part suitable for textile purposes, such as jute or paper-yarn substitute, and a part containing starch and sugar suitable for production of alcohol or cattle fodder by fermentation processes.—B. V. S.

Rushes; Preparation of valuable fibres from —. Deutsche Typha-Verwertungsges.m.b.H., Charlottenburg. Ger. Pat. 308,564, 20.1.18.

THE rushes are crushed, treated with weak alkali, and then with dilute bisulphite solution, preferably at boiling temperature. Long, white, pliant fibres, suitable for spinning and of considerable strength are obtained.—B. V. S.

[Pea-pods;] Fibrous material [from —]. R. Pöhler, Frankenthal. Ger. Pat. 307,626, 19.2.18.

By a fermentation process or by treatment with hot water or steam the outer layer of pea-pods is dissolved away, leaving the inner fibrous layer in a form suitable for spinning etc. The solution of the outer layer contains sugar and is suitable for use in the preparation of marmalade etc.—B. V. S.

Typha fibres; Process for the after treatment of — separated by a chemical process. Deutsche Typha-Verwertungsges.m.b.H., Charlottenburg. Ger. Pat. 308,563, 28.11.17.

THE fibres are washed and then boiled with sodium bisulphite solution either in open vessels or in closed vessels under pressure.—B. V. S.

Textile materials; Process for waterproofing and softening —. L. Meyer, Charlottenburg. Ger. Pat. 314,968, 13.12.18.

THE material is treated first with a solution of a metallic salt, then dried and treated with an alkali and finally with soap or similar substance. For instance, artificial silk may be treated with aluminium formate, dried at 40°—45° C., then treated with ammonia, and lastly with a soap solution at about 50° C.—B. V. S.

Waste from paper industries; Process for rendering — absorbent. Reis und Co., Friedrichsfeld. Ger. Pat. 307,611, 20.2.18. Addition to Ger. Pat. 303,302 (this J., 1920, 15A).

AFTER the chemical treatment and before drying the waste is left for a long time exposed to the action of the solution of the residue of softening reagent (alkali etc.) remaining in the material.

This gives a more permanent absorbent quality than if the softener is thoroughly washed out before drying.—B. V. S.

Fabric for aircraft and process of making same. N. A. T. N. Feary, Peterborough. U.S. Pat. 1,327,707, 13.1.30. Appl., 21.4.19.

See Eng. Pat. 123,690 of 1918; this J., 1919, 678 A.

Paper; Process for making lines and water-marks on — and apparatus therefor. O. Suursalmi, Assignor to Kangas Pappersbruks Aktiebolag, Jyväskylä, Finland. U.S. Pat. 1,329,100, 27.1.20. Appl., 13.8.19.

See Eng. Pat. 123,082 of 1919; this J., 1919, 896A.

Saccharification of wood etc. Ger. Pats. 305,180, 309,150, and 310,149—50. See XVIII.

Cellulose products. Ger. Pat. 305,019. See XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Ink stains; Removal of — [from fabrics]. Gerhardt. Z. angew. Chem., 1920, 33, 32.

AN ink stain on a cotton cloth resisted the action of oxalic acid, oxalic acid and sodium chloride, and oxalic acid and zinc dust, but was removed completely by treatment with dilute potassium permanganate solution followed by sodium thiosulphate and citric acid, and subsequent washing with water.—W. P. S.

PATENTS.

Silk; Increasing the strength and elasticity and preventing or decreasing the subsequent weakening of fibres of loaded —. J. Korselt, Zittau, Saxony. Eng. Pat. 136,578, 24.8.17. (Appl. 12,188/17.) Addition to 101,684/16 (this J., 1918, 53 A).

THE strength and elasticity are increased or the subsequent weakening of loaded silk fibres is prevented or decreased by treating the silk with berberine or with alkaloid derivatives or decomposition products which can be produced synthetically, such as tropine, or methyl-phenmorpholine, or pimelic acid, or compounds produced by the fermentative or chemical decomposition of protein or nuclein, such as amino-acids of the aliphatic or aromatic group; hydroxyamino or thioamino acids; heteronuclear compounds of the iminazole, pyrrole, and indole groups; polypeptides and peptones; proline, histidine, tryptophane, protamines, histopeptone, etc.; guanine, cytosine, thymine, uracil, guanylic acid, inosinic acid, etc. All these compounds are oxidised by the loading material or by the oxygen of the air more readily than the fibroin of the silk. These compounds modify the handle of the silk by rendering it softer and prevent the action of the loading agents on the fibre as well as preventing or diminishing rotting with age resulting from the oxidation of the fibroin. After treatment with these protective agents the loaded silk showed an increase of 50—60% in strength and 25—40% in elasticity.—L. L. L.

Dyeing, washing, scouring, sizing, bleaching, and mercerising yarn in hank form; Machines for —. J. S. and S. S. Lord, Manchester. Eng. Pat. 136,666, 31.12.18. (Appl. 21,864/18.) Addition to 121,075/18 (this J., 1919, 71 A).

THE machine described in the chief patent is modified to enable it to be used for dyeing or treating hanks with different dyes or reagents. Each of the rollers is provided with a trough which when the arm carrying the respective rollers approaches the

vertical position is automatically charged with dye or reagent, and after the hanks are treated automatically emptied. A device is attached to the hank rollers for feeding or stripping the machine, and a suitable form of reversible gear is provided.—L. L. L.

[Indigo] dyeing machines. F. and F. Davis, Halifax. Eng. Pat. 136,991, 14.5.19. (Appl. 9108/19.)

A MACHINE for the dyeing of indigo on woollen or worsted piece goods comprises a vat containing an upper and lower tier of rollers submerged in the dye liquor. The upper tier consists of rollers of two diameters, the larger rollers being arranged alternately to two or more of the other rollers. The larger rollers are driven by means of chains and chain wheels, and resting on the driven rollers are jockey or nip rollers. The goods are taken through the liquor under a uniform tension, causing little or no disturbance of the dye bath; consequently there is no risk of curled edges, creases, or premature oxidation with resulting streaky dyeing.—L. L. L.

Dye and process of dyeing. J. A. Nieuwland, Notre Dame, Ind. U.S. Pat. 1,326,367, 30.12.19. Appl., 3.12.17.

THE dye-bath is prepared by the action of a mercuric salt upon a solution of *p*-phenylenediamine above the normal temperature. Fabrics may be dyed by subjecting them to the successive action of solutions containing respectively a mercuric salt and *p*-phenylenediamine.—L. L. L.

Paper yarn and cloth; Process for dyeing —. Chem. Fabr. Coswig-Anhalt, G.m.b.H., Coswig. Ger. Pat. 315,311, 15.3.18.

OXIDISING agents, such as perborate, percarbonate, etc., are added to the dye-bath. Brighter colours are obtained and the substance is softer to the touch, is more easily impregnated by waterproofing solutions etc., and is stronger than when dyed in the absence of the oxidising agent.—B. V. S.

Printing fabrics or the like; Machines for —. A. Samuel, Lyons, France. Eng. Pat. 126,946, 20.3.19. (Appl. 6926/19.) Int. Conv., 16.5.18.

THE machine comprises two carriages arranged to move at right angles to each other, one of these carriages being displaceable along the length of the printing table on which the fabric is placed, whilst the other carriage, carrying the printing device, is displaceable transversely for the purpose of printing the design of an engraved roller across the entire width of the fabric. When a strip has been printed, the first carriage is displaced longitudinally for a distance equal to the width of the printed strip and the second carriage, brought back to the rear, prints a new strip fitting adjacent to and in exact alinement with the first. The machine is fitted with a device for turning the printing rollers and also for raising these rollers during their return to the rear in order to avoid contact with the fabric.—L. L. L.

Colour fastness in dyed fabrics; Apparatus for testing —. J. W. Driver and F. W. Sunderland, Bradford. Eng. Pat. 136,971, 8.3.19. (Appl. 5788/19.)

THE dyed material is exposed in a frame to the concentrated beam of an arc lamp from which the infra-red or heat rays have been substantially removed by a light filter. The arc light is condensed by a plano-convex lens and projected on to a double convex lens, the frame holding the sample of fabric to be tested being placed slightly beyond the focus of the last lens. If necessary, a colour screen is interposed to act as a filter for infra-red or heat rays.—L. L. L.

Mergerising, dyeing, and other operations; Means for supporting and stretching hose and like knitted fabrics upon wire forms during —. A. E. Hawley, Hinekey, P. F. Crosland, Halifax, and F. G. Dixon, Cheadle Hulme, Eng. Pat. 137,386, 22.1.19.

[*Aniline*] *Black; Production of* — upon vegetable textile fibres, silk fibres, or mixtures of the same. E. A. Fourniaux, Manchester. U.S. Pat. 1,329,117, 27.1.20. Appl., 27.5.19.

SEE Eng. Pat. 126,201 of 1918; this J., 1919, 460A.

Starch. Eng. Pats. 135,591 and 135,588. See XVII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Coal pyrites; Chemical data on —. H. F. Yancey. Chem. and Met. Eng., 1920, 22, 105–109.

A GEOLOGICAL survey indicated that about 1,500,000 short tons of pyrites concentrates could be recovered from coal mining operations in the Eastern and Central coalfields of the United States. The sulphur content of about 120 collected samples, freed from adherent coal, was found to be in most cases sufficiently high for economic treatment in the manufacture of sulphuric acid. The colour of the specimen was no index of the probable purity, as many of the samples containing more than 45% of sulphur were dirty gray and non-crystalline, while bright brass-yellow crystals were often found to be low in sulphur value. The carbon contained in picked or washed pyritic material is not injurious, as material containing up to 10% of bituminous matter has been used for making sulphuric acid without trouble. Pyrites from coal contains only very small quantities of arsenic (0.005–0.056%) and phosphorus (0.003–0.083%), and a considerable proportion of the burnt cinder could be used for the production of low-phosphorus iron.—C. A. K.

Sulphuric acid, nitric acid, and their mixtures; Specific heat of —. P. Pascal and Garnier. Bull Soc. Chim., 1920, 27, 8–18.

Using an electrical method of heating, the authors have determined the specific heat of sulphuric acid at concentrations varying from 10 to 100% of acid, of nitric acid at concentrations varying from 10 to 98%, of mixtures of nitric acid and sulphuric acid, and of mixtures of nitric acid, sulphuric acid, and water in varying proportions. The results are set out in detail.—W. G.

Ammonia; Advantages of the synthesis of — at very high pressures. G. Claude. Comptes rend., 1920, 170, 174–177.

NUMEROUS advantages are claimed for the use of pressures up to 1000 atmos. (see this J., 1919, 885 A; 1920, 61 A) instead of 200 atm. as in the German method, in the synthesis of ammonia on an industrial scale. The contact chamber can be very materially reduced in size for the same production, and it is only necessary to pass the reacting gases over the catalyst three times instead of the considerable number of times necessary at the lower pressure. Again, at the higher pressure much more heat is evolved and may be used to produce power, and auto-reaction can be realised in much less cumbersome apparatus. At the high pressure the percentage of ammonia in the issuing gases may be 25%, and its partial pressure such that simple cooling with water is sufficient to liquefy the greater proportion of the ammonia as it issues from the reaction chamber. The ammonia in this form can be readily liberated as gas and thus easily used in the ammonia soda process. Finally, there is very little loss of pressure in the high-pressure pro-

cess compared with the German method, as it is only necessary to circulate the gas three times over the catalyst and the ammonia can easily be removed from the gases issuing from the reaction chamber.

—W. G.

Ammonia; Catalyst for the oxidation of —. G. A. Perley. Chem. and Met. Eng., 1920, 22, 125–129.

THE DIVERGENCE in the type of platinum catalyst employed in different installations is emphasised. Since the reaction is essentially a contact process a gauze of 0.0025 in diam. wire and of 120–150 mesh is more logical from the standpoint of economy in platinum than the gauze of larger mesh generally used. A three-layer gauze arrangement of mantle form represents the maximum upper limit for the economical use of platinum, and the layers should be separated in order to permit the much-diluted ammonia-air mixture, which passes the first layer, to be heated to a higher temperature than the original, more concentrated ammonia mixture. A suitably preheated mixture of gases is important if a rapid velocity of reaction is to be attained. It is probable that nitric oxide (NO) is not the initial product of the ammonia oxidation reaction. The decomposition reactions are dependent on the gas velocity, and for the efficient use of spaced gauzes a correct adjustment of the space-time-temperature factor is necessary.—C. A. K.

Hydrogen; Formation of free — in the reversed ammonia flame. F. C. G. Müller. Z. angew. Chem., 1920, 33, 24.

THE author finds that the products of combustion of ammonia in oxygen contain hydrogen and nitrogen in the ratio 2:3 by volume. Since the result is unaltered by cooling the flame by cold water (Raschig, Z. phys. Chem. Unterr., 1918, 138), it cannot be due to dissociation of ammonia. On the other hand, Raschig's assumption that the equation $2\text{NH}_3 + \text{O}_2 = \text{N}_2\text{H}_4 + 2\text{H}_2\text{O}$ represents the first stage of the reaction, followed by instantaneous dissociation of N_2H_4 and partial combustion of the hydrogen, does not account for the constancy of the proportion of hydrogen produced.—J. K.

Nitrogen trioxide; Existence of — in the gaseous state. E. Wourzel. Comptes rend., 1920, 170, 109–111. (See also this J., 1920, 151 A.)

Measurements of the contraction occurring when known quantities of nitric oxide and oxygen are mixed, the nitric oxide being in excess, indicate that, under a total pressure of about 0.25 atm., an almost stoichiometric mixture of nitric oxide and nitrogen peroxide contains about 25% of nitrogen trioxide.—W. G.

Nitric oxide; Velocity of oxidation of —. E. Wourzel. Comptes rend., 1920, 170, 229–231.

THE oxidation of nitric oxide is a reaction of the third order and shows no noticeable modification when half the nitric oxide is oxidised. The formation of nitrites or nitrosyl sulphate, observed when the gaseous products formed at the commencement of the reaction are treated with alkali or sulphuric acid, must be due to particular conditions of absorption and not of oxidation. Nitrogen trioxide is an ultimate product of the action and not an intermediate product. The velocity of the oxidation diminishes with rise in temperature.—W. G.

Sodium nitrite; Reversible oxidation of —. C. Matignon and E. Monnet. Comptes rend., 1920, 170, 180–182.

IT is well known that sodium nitrate is decomposed by heat, giving sodium nitrite and oxygen. It is now shown that if sodium nitrite is heated in oxygen at a pressure of 175 atm., the temperature being gradually raised during 9 hours from 395° C. to 530° C., it is almost entirely converted into

sodium nitrate. The heat of formation of the nitrate is given by $2\text{NaNO}_3\text{sol} + \text{O}_2 = 2\text{NaNO}_2\text{sol} + 45$ cals. The reaction is, however, too slow for practical application. Calcium nitrite is similarly converted into calcium nitrate.—W. G.

Sodium nitrite; Some properties of —. C. Matignon and G. Marchal. *Comptes rend.*, 1920, 170, 232–233.

Sodium nitrite has m. pt., 276.9°C . (corr.). The following heat equations have been found for it:—

Aqueous sodium nitrite is not oxidised at 100°C . by prolonged contact with oxygen under a pressure of 50–55 atm. even in the presence of a catalyst.

—W. G.

Sulphates; Volumetric determination of — by oxidation of benzidine sulphate with potassium permanganate. P. L. Hibbard. *Soil Sci.*, 1919, 8, 61–65.

A MODIFICATION of the method of Raiziss and Dubin (*J. Biol. Chem.*, 1914, 18, 297). The solution for the precipitation of benzidine sulphate should be free from iron, heavy metals, nitrates, phosphates, and organic matter, and should only contain between 0.5 and 1.0 mgrms. of SO_4 . The liquid (10–25 c.c.) is treated with one drop of phenolphthalein and then with dilute sodium hydroxide till just alkaline. It is then neutralised with $\text{N}/10$ hydrochloric acid and 0.1 c.c. added in excess for each 5 c.c. of solution. Keeping the liquid quite cold, 5 c.c. of 0.8% benzidine hydrochloride solution is added, and after 15–30 minutes the benzidine sulphate is collected in a Gooch crucible, washed with the minimum of cold water, transferred with the asbestos pad to the precipitation flask, and heated with 1 c.c. of 10% sodium hydroxide solution in a boiling water bath for a few minutes. Then 10 c.c. of dilute sulphuric acid (1 acid:1 water) is added and hot water to bring the volume to 100 c.c. $\text{N}/20$ potassium permanganate is run in until there is 5 c.c. in excess and the solution heated on the water bath for exactly ten minutes. Then 10 c.c. of $\text{N}/20$ oxalic acid is added and the titration completed with $\text{N}/20$ permanganate. The factor for the conversion of c.c. of permanganate solution into mgrms. of SO_4 is 0.12. It is advisable to make a blank determination.—W. G.

Calcium carbide manufacture; Notes on —. J. Baumann. *Chem.-Zeit.*, 1920, 44, 33–35.

Good contact between the electrode and its holder is essential; intermediate layers of copper gauze or a coating of graphite-dextrin paste tend to burn out the holder. The most suitable form of holder is the "copper pin" type. By the use of sprinklers for cooling the electrode holders water is economised and loss of current and risk of explosion in the furnace are avoided. Electrodes should be carefully prepared from good anthracite; they should have a fine-grained structure and should emit a ringing sound. If they are heated to too high a temperature they flake and disintegrate. The size of the raw materials is important. If the pieces are too large a deposit of carbide forms on the electrodes and lowers the potential. Dust in the "carbide smoke" may be removed by a cyclone; efforts to recover the lime formed by combustion of metallic calcium produced by dissociation of the carbide have so far been unsuccessful. By careful avoidance of local overheating through selection of the correct size of electrodes, the amount of "smoke" is reduced to a minimum. The life of the electrodes has an important bearing on econo-

mical running. The use of jackets, or coating the surface, to protect the electrodes from the effect of atmospheric oxygen is not effective. Means by which the raising and lowering of the electrodes are avoided would promise better results. The consumption of electrodes by carbide formation might be diminished by manufacturing carbide of lower strength than 80%. In continuing to use electrodes after they have burned down, the possible destruction of the more expensive electrode-holder must be borne in mind.—W. J. W.

Carbide furnace gases. P. Schl pfer. *Z. Elektrochem.*, 1919, 25, 409–414.

THE author has examined the gases and the dust from the electric furnaces used for the manufacture of calcium carbide. The carbon monoxide content of the gas was a maximum in the immediate vicinity of the electrodes; one such sample showed: CO_2 , 1.00%; O_2 , 1.33%; CO , 84.64%; H_2 , 5.82%; N_2 , 7.21%; whilst a sample taken 50 cm. from the electrode close to the surface of the charge gave: CO_2 , 15%; O_2 , 2.55%; CO , 16.53%; H_2 , 56.13%; N_2 , 9.79%. The combustion of the gases in the case of open furnaces, actually starts in the reacting mass and is completed so rapidly that carbon monoxide cannot be detected in the gases coming from the furnace. There is no noticeable damage done to plant life in the neighbourhood of carbide furnaces. For the manufacture of 1000 kilos. of carbide (containing 85% CaC_2) 1000 kilos. of lime and 600 kilos. of coke are used. There is a loss of 121 kilos. of lime, 60 kilos. of coke ash, and 23 kilos. of coke dust, all of which must be carried away by the gases in the form of dust. This dust is described as the plague of the carbide industry. A number of analyses of the dust, collected in different ways, are quoted. A sample collected in a coke scrubber contained: Sol. in HCl : MgCO_3 , 3.03%; CaCO_3 , 12.54%; CaO , 24.44%; CaSO_4 , 3.09%; Fe_2O_3 , 4.66%; SiO_2 , 3.77%; insoluble in HCl : C , 34.84%; ash, 9.58%; S and O_2 , 2.11%; H_2 , 0.49%. A sample from a settling tank, collected in the wet way, contained a much higher proportion of calcium carbonate and less lime, the latter having been further converted into carbonate by the CO_2 of the gases through the solvent action of the water. It is concluded that the dust from the furnaces originally contains much lime, which gradually becomes converted into carbonate. The amount of dust produced is proportionately much greater from larger furnaces than from smaller ones, and increases with increasing voltage. It also depends on the manner in which the furnace is worked and is lessened by the use of coarser grained lime. The author has calculated the heat balance-sheet of the process, and shows that the heat of the gases, if it could be utilised, is sufficient to burn more than half the lime used in the manufacture.—E. H. R.

Chromic acid; Continuous process for the regeneration of —. R. H. McKee and S. T. Leo. *J. Ind. Eng. Chem.*, 1920, 12, 16–26.

THE organic matter in waste chromium liquors may be destroyed by means of an electric current without any preliminary treatment. The best results are obtained at the ordinary temperature, and hard lead is the most suitable material for the anode. Preliminary filtration of the waste liquor from suspended organic matter (through a sand filter 2 in. deep) is important. In a continuous process of regeneration the fresh waste liquor was fed directly into the bottom of one end of the cathode chamber, and overflowed through an orifice at the other end into the anode chamber, in which the level of the electrolyte was kept somewhat lower. The finished solution was drawn off continuously at the opposite end of the anode chamber. The acid concentration in the cathode chamber was restored by the supply of fresh waste liquor, whilst

in the anode chamber it was reduced and balanced by the overflow liquid from the cathode chamber. The cell was rectangular, and the diaphragm was composed of "electro-filtros." In commercial practice a solution of 70 grms. CrO_3 equivalent per litre is commonly used as oxidising agent, so that the concentration of the anolyte should be maintained above that limit. Better results were obtained with a concentration of 96 grms. than with 80 grms. per litre. For a given current density the capacity of the cell is directly proportional to the anode surface. With a current density of 1.2 amp. per sq. dm. the equivalent of about $\frac{1}{3}$ lb. of chromic anhydride is produced in 24 hours for an anode surface of 8 sq. dm.; whilst with a current density of 2.4 amp. per sq. dm. about $\frac{1}{11}$ lb. is produced in 24 hours with same anode surface. Only about 3 k.w.h. of electric energy is required for each lb. of chromic acid regenerated, and the value of the sulphuric acid simultaneously regenerated is nearly as great as the cost of the electric energy.—C. A. M.

Adsorption and adsorption compounds. V. Adsorption compounds of cuprous oxide. L. Berzeller. *Biochem.-Zeits.*, 1919, 93, 230—237.

In precipitating cupric hydroxide from copper sulphate with sodium hydroxide some of the alkali is adsorbed by the precipitate. The black hydroxides adsorb more of it than the blue ones. Iodate ions are also adsorbed by cupric hydroxide, but in this case the blue hydroxides adsorb more of it than the black. The presence of sugar prevents the adsorption of sodium hydroxide by cupric hydroxide.

—S. S. Z.

Hydrocyanic acid; Identification of traces of —. Chelle. *Bull. Soc. Pharm. Bordeaux*, 1919, No. 2. *Ann. Chim. Analyt.*, 1920, 2, 21—21.

The phthalein test and the isopurpurate test may be used, but they are not specific reactions of hydrocyanic acid. The ammoniacal silver iodide test is specific, but conversion of the hydrocyanic acid into Prussian blue is the most trustworthy test; it may be used to identify the hydrocyanic acid in mercury cyanide or silver cyanide. (See also this J., 1911, 837; 1917, 195; 1919, 899 A.)—W. P. S.

Thiocyanogen; Free —. E. Söderbäck. *Annalen*, 1919, 419, 217—322.

Lead thiocyanate reacts completely with a dry ethereal solution of bromine cooled by ice-water to form lead bromide and a solution of thiocyanogen, CNS. Other organic solvents may be used and the lead thiocyanate replaced by silver, cadmium, mercury, zinc, thallium, or copper thiocyanate. A solution of chlorine in carbon tetrachloride reacts in the same way with silver or mercury thiocyanate, but not with lead thiocyanate. A solution of iodine in an organic solvent reacts with certain thiocyanates similarly, but in no case does the reaction attain completion. The solution of thiocyanogen converts iron powder into ferric thiocyanate and cuprous thiocyanate into cupric thiocyanate, and liberates iodine from solutions of iodides. By cooling an approximately $N/2$ solution of thiocyanogen in carbon bisulphide the substance is obtained in colourless crystals which melt at -3° to -2° C. and decompose at the ordinary temperature. (See also J. Chem. Soc., March, 1920.)—C. S.

Potassium anhydrotellurate; A reaction of —. P. Hulot. *Bull. Soc. Chim.*, 1920, 27, 33.

If potassium anhydrotellurate is suspended in hydrochloric acid (1 acid:2 water) and a few fragments of zinc are added the whole of the tellurium is precipitated as a powder.—W. G.

Welding of solid powders under pressure. T. von Hagen. *Z. Elektrochem.*, 1919, 25, 375—386.

An extensive series of experiments is described on

the behaviour of pure powdered inorganic substances when compressed into tablets, the object being to determine how the hardness, form, and strength of the tablet are influenced by the properties of the original material, such as its hardness, melting point, and crystalline form, by the size of grain of the powder, by the degree of pressure employed, and by the addition of other substances. Generally the substance examined was ground to pass a sieve of 25 meshes per sq. mm., and the tablets were formed under a pressure of 560 kilos. per sq. cm. The substances examined included oxides, sulphides, sulphates, halides, nitrates, and carbonates of many metals. The halogen compounds of the alkali metals all gave solid homogeneous tablets, the hardness of which was greater the higher the melting point of the salt. The anhydrous sulphates and the stable hydrated sulphates gave mechanically weak, "powdery" tablets or showed no cohesion, whilst those hydrated sulphates stable only at low temperatures, such as $\text{Al}_2(\text{SO}_4)_3$, $18\text{H}_2\text{O}$, gave "smooth" tablets (smooth surface with pulverulent interior) of high crushing strength. Oxides gave "powdery" tablets with the exception of PbO and PbO_2 , which gave "smooth" tablets. The sulphides and nitrates mostly gave "smooth" tablets, whilst those from most of the carbonates were "powdery." Calcium fluoride, silica, and carborundum show practically no cohesion. The influence of grain size is very marked in those substances which form "smooth" and "powdery" tablets, the hardness of the tablet being much greater with a fine-grained than with a coarse powder. When a substance having good binding properties was mixed in varying proportions with another which alone showed no cohesion, the effect was not proportional to the amount of the binding substance added; thus when potassium chloride was mixed with silica the improvement in the strength of the tablet was small up to 25% KCl and afterwards increased rapidly as the proportion of KCl increased. The curves obtained were much more regular when fine-grained particles were used than with coarse particles. Both hardness and density of the tablet, in the case of "powdery" and "smooth" bodies, increased with increasing pressure up to 9800 kilos. per sq. cm.; the density increased rapidly up to a certain point, beyond which it was practically constant. In the case of gypsum the final density under high pressure was equal to the density of the crystals, and in the cases of sodium and potassium chlorides the true density of the substance was very nearly attained. Those substances which form "plastic" crystals have the best cohesive properties under pressure, probably because the crystal particles, being deformable under pressure, are better able to expel the entrapped air particles and bind together than non-plastic crystals.—E. H. R.

PATENTS.

Acids; Manufacture of —. Sulphuric acid manufacture. E. D. Chaplin, New York. U.S. Pats. (A) 1,325,711 and (n) 1,325,712, 23.12.19. Appl., 27.1.16 and 10.3.16.

(A) CONCENTRATED sulphuric and hydrochloric acids are simultaneously formed by mixing sulphur di-

oxide, chlorine, and an inert gas with steam, the mixing being effected whilst reducing the pressure to which the steam is subjected. (b) Chlorine, employed in the manufacture of sulphuric acid, is again used by circulating hydrogen and chlorine continuously in a multi-stage circuit, the gases whilst combined as hydrochloric acid being mixed with oxygen and a neutral gas, each being supplied to the circuit at one stage thereof in a continuous stream. The mixture is heated to form water vapour and liberate the chlorine, whilst in a further stage sulphur dioxide and steam are supplied in continuous streams. The sulphur dioxide is converted into the trioxide, and the hydrogen liberated from the water vapour forms hydrochloric acid.

—B. N.

Nitric acid vapours; Condenser for —. A. Hough, New York. U.S. Pat. 1,326,267, 30.12.19. Appl., 30.1.19.

A VERTICAL, sectional casing contains a number of pipes arranged transversely, one above the other, and joined at adjacent ends—the joints being outside the casing—to form a continuous, zig-zag channel for the passage of the acid vapour. Inlet and outlet pipes for the cooling fluid are provided at the top and bottom of the casing, in which baffles are also disposed to compel the cooling fluid to traverse a tortuous path.—W. E. F. P.

Nitrous gases; Process for the sudden cooling of hot —. R. Mewes, Berlin. Ger. Pat. 298,846, 15.3.14.

THE hot gases are quickly and intimately mixed with 1–6 times their volume of previously cooled compressed air at the same or higher pressure, and the gas mixture is allowed to expand in an expansion engine so that the greater part of the heat and mechanical energy can be utilised to perform useful work, e.g., to compress the oxygen necessary for the reaction. The nitrous gases are then used for the manufacture of nitric acid or alkali nitrates.—A. R. P.

Ammonia; Catalyst for the oxidation of — by air or oxygen. W. Manchot and J. Haas, Munich. Ger. Pat. 300,651, 1.8.16.

SILVER oxide is intimately mixed with pumice and reduced by hydrogen at a little below 100° C., or with carbon monoxide at the ordinary temperature. Owing to the heat produced in the reaction the latter gas is, preferably, mixed with a considerable amount of air or nitrogen and passed over the mass at a temperature not exceeding 40° C. The silver oxide should be pure and dry; even very small quantities of impurities greatly impede the reduction. Ammonia, mixed with air or oxygen, is passed over the catalyst, which is heated until the reaction commences, after which sufficient heat is generated to continue the combustion. The temperature of the mass may be lowered to a barely visible red-heat or lower by altering the rate of flow of the gases. Oxides of nitrogen are the chief products at the higher temperatures and nitric acid at the lower.—A. R. P.

Nitric acid; Process for the production of high-grade —. Wülfing, Dahl, and Co. A.-G., Barmen. Ger. Pat. 300,712, 28.6.14.

ENOUGH strong nitric acid is mixed with sulphuric acid to make the H_2SO_4 content of the mixture equal to that of 60° B. (1.71 sp. gr.) acid. Saltpetre is then added and the mixture distilled, keeping the temperature as long as possible between 100° and 135° C. In this way all the nitric acid added, together with 60–70% of that in the nitrate, is recovered as acid of 48° B. (1.495 sp. gr.), and no decomposition of the nitric acid takes place.

—A. R. P.

Tungstates; Method of and means for the separation of fusible — from the gangue resulting from the decomposition of the ore. C. J. Head, London. Eng. Pat. 136,577, 27.6.17. (Appl. 9215/17.)

A MIXTURE of the finely-divided gangue material with alkali is heated on a plain hearth to produce alkali tungstate, and the charge is transferred to a perforated hearth which forms the cover of a filter-bed through which the molten alkali tungstate drains to the furnace well beneath. The two hearths, consisting of iron plates, are arranged side by side in the furnace. The filter consists of a layer of scrap iron turnings or/and other material, preferably containing wolfram, enclosed between the perforated hearth and a lower perforated plate. The function of the wolfram in the filtering medium is to enrich the alkali tungstate at the expense of any free alkali present.

—W. E. F. P.

Cyanides [for the preparation of ammonia]; Production of —. C. T. Thorssell and H. L. R. Lundén, Gothenburg, Sweden. Eng. Pat. 136,772, 20.6.19. (Appl. 15,560/19.)

IN the production of ammonia by the action of water on cyanides prepared by heating mixtures of coal with alkali- or alkaline-earth metal compounds in a current of nitrogen, the activity of the reaction mass becomes impaired by the formation of alkali- or alkaline-earth silicates and aluminates. According to the present invention the latter compounds are decomposed, and the silica etc. precipitated, after the ammonia-producing stage, by dissolving (or suspending) the mass in water and treating the solution with carbon dioxide or an acid stronger than silicic acid, but containing no element other than oxygen, hydrogen, carbon, and nitrogen (e.g., formic or acetic acid); or by making the solution caustic by the addition of lime.—W. E. F. P.

Chromium; Process of isolating salts of —. G. N. Vis, Paris. U.S. Pat. 1,324,328, 9.12.19. Appl., 22.1.18.

IN the recovery of chromium salts from chrome ores treated with alkali hydroxides the latter are dissolved out by means of organic solvents, and the alkali carbonates, aluminates, and silicates are separated from the chromates by means of carbon dioxide.—J. H. L.

Alkaline-metal monochromates; Process for transforming — into bichromates. G. N. Vis, Paris. U.S. Pat. 1,326,123, 23.12.19. Appl., 18.12.18.

A SOLUTION of alkali monochromate is treated with carbon dioxide and ammonia in presence of excess of ammonium bicarbonate, whereby sodium bicarbonate is precipitated and a solution of ammonium chromate obtained. The latter is treated with lime to produce calcium chromate, which is then converted into alkali bichromate by the addition of alkali bisulphate.—W. E. F. P.

Potassium carbonate; Manufacture of —. E. D. Chaplin, Montclair, N.J. U.S. Pat. 1,325,713, 23.12.19. Appl., 29.12.14.

A MICA mineral is heated with an alkali hydrate (hydroxide) to the point of fusion of the mica, and the product obtained is subjected, whilst the mica is still molten and under conditions to form carbon dioxide, to the action of a "carbon-supplying material" in the presence of oxygen.—B. N.

Barium oxide; Manufacture of —. H. Fleck, Golden, Colo. U.S. Pat. 1,326,332, 30.12.19. Appl., 5.11.17.

A MIXTURE of barium carbonate with petroleum coke is heated to the reduction temperature in a non-silicious container.—W. E. F. P.

Alumina from clay; Process for the extraction of —. H. G. Wildman, Montreal, Canada. U.S. Pat. 1,326,384, 30.12.19. Appl., 6.2.18.

THE alumina of the clay is first rendered soluble and then dissolved in the presence of sulphur dioxide.—W. E. F. P.

Aluminium hydride; Process for extraction of — from refractory bauxites. Recovery of aluminium hydride from strong aluminate liquors. I. Szirmay and A. Tet tleni, Budapest. Ger. Pats. (a) 299,652 and (b) 299,653, 25.1.16.

(A) BAUXITE is heated at 170° C. with caustic soda solution of 45° B. (sp. gr. 1.454) and sufficient lime to combine with the silica (1.7 mols. Na₂O and 1—2 mols. CaO to 1 mol. SiO₂) until the density of the solution rises to 50° B. (sp. gr. 1.53). The iron and titanium are precipitated as oxides and the silica as calcium silicate, and 96—98% of the alumina is obtained as a pure concentrated solution of sodium aluminate. (B) Cold water is added in several portions to the hot alkaline solution; after each addition the mixture is stirred and the precipitate filtered off. The number of steps necessary and the quantity of water added each time depend on whether it is desired to precipitate the greater part of the alumina or to recover the caustic soda in a more highly concentrated solution, and thus reduce the costs of re-concentrating it for use again in the process. The precipitate is washed with a small quantity of water, then digested hot with a solution of an ammonium salt, especially the chloride or sulphate; the resulting sodium salt is easily removed by further washing.—A. R. P.

Method of digesting finely-divided materials. [Extraction of potash from minerals.] T. C. Meadows, New York, and F. L. Sample, Teaneck, N.J., Assignors to American Potash Corporation, New York. U.S. Pat. 1,326,412, 30.12.19. Appl., 6.12.18.

IN a method of digesting a mixture of lime, water, and finely-divided potassium-bearing mineral under pressure the mixture is forced continuously through a heated pipe coil in which the desired pressure is maintained, and the potassium-bearing solution is separated.—W. E. F. P.

[Calcium] cyanamide-oven. G. E. Cox, Niagara Falls, N.Y., Assignor to American Cyanamid Co., New York. U.S. Pat. 1,326,412, 30.12.19. Appl., 21.7.19.

IN a cyanamide oven having a refractory lining and a resistor the latter is surrounded by a combustible tube, and a number of supporting, non-combustible surfaces, separated by interstices, are provided in close proximity to the refractory lining. A smooth sheet of combustible material rests against these supporting surfaces, and means are provided for introducing nitrogen into the oven and for conveying the gas thence to the tube.

—W. E. F. P.

Sulphur; Preparation of — from sodium bisulphate. A.-G. Dynamit Nobel, Vienna. Ger. Pat. 300,762, 18.4.16.

SODIUM bisulphate is heated with carbon and the issuing gases are passed into a solution of the sodium sulphide produced in a previous operation. The resulting solution of thiosulphate and sulphide is acidified with sulphuric acid or, preferably, bisulphate. The sodium sulphide may also be treated with the condensed gases produced during the reduction of the sulphate in such a manner that sulphur dioxide is always present in excess to prevent formation of, or decompose, hydrogen sulphide. The black bisulphate produced as described in Ger. Pat. 263,120 (this J., 1913, 909) may be calcined, giving the normal sulphate and sulphur dioxide;

the former is reduced to sulphide, which is treated with the gases produced during the calcining operation.—A. R. P.

Iron oxide slimes produced in the removal of iron from industrial water; Process for the conversion of — by aeration into a chemically active form. Praetorius und Co., Breslau. Ger. Pat. 305,083, 20.1.17.

THE material is dried and heated until incandescence spreads throughout the mass, which is then cooled out of contact with the air. The product, which consists of ferric and ferrous oxides, with possibly a small amount of metallic iron, dissolves slowly but almost completely in lemon-juice at 80° C. It is converted by ignition in the air into ferric oxide, which may also be prepared by continuing the heating of the original material in the air for some time after incandescence has ceased. The ferric oxide may be used as a pigment, for the preparation of thermit mixtures, or for the preservation of food.—A. R. P.

Ferrosoferric oxide; Process for the production of a — suitable for aluminothermic use. G. Bredig, P. Askenasy, and E. Schlumberger, Karlsruhe. Ger. Pat. 314,697, 19.2.16.

FERRIC oxide, e.g., burnt pyrites substantially free from sulphur, is charged continuously into a shaft furnace, through which an ascending or descending current of combustible gas is passed, the operation being so controlled that the reaction takes place in a manner similar to surface combustion; the molten material is discharged at the bottom. This product, which contains more ferrous oxide than corresponds to the formula Fe₃O₄, is atomised according to known methods, e.g., by forcing steam through the molten mass.—A. R. P.

Ammonium sulphate; Production of — from coal gas or producer gas. C. Francke, Berlin. Ger. Pat. 314,598, 30.12.17.

THE gas is mixed with sulphur dioxide at a temperature between 60° and 80° C. Dust is removed from the mixture, for example, by electrical precipitation, and the cleaned gas is subjected to the action of ozone. The ozone should be of high concentration and used in such quantity that the mixture does not contain more than 4% of oxygen. Sulphur is deposited along with liquid products of the reaction, and after separating it by filtration the filtrate is evaporated. A residue of ammonium sulphate is thus obtained. The sulphur dioxide driven off is used to treat a further quantity of gas.

—J. S. G. T.

Thionate solutions containing sulphite and bisulphite, such as are obtained by washing gases containing ammonia and hydrogen sulphide with polythionate solutions; Conversion of — into pure thionate solution. W. Feld, Linz. Ger. Pat. 314,628, 27.8.18.

SULPHUR is introduced into the solution at a temperature above the melting point of sulphur. The sulphur may be previously heated or melted, and the thionate solution, prior to, during, and subsequently to the introduction of the sulphur, is heated under pressure. The molten particles of sulphur come into intimate contact with the hot liquor, and thiosulphate formation is soon initiated. Loss of ammonia is diminished by working under pressure.

—J. S. G. T.

Monazite sand; Process for decomposing —. Chem. Fabr. Heilgensee Dr. V. Helholt und Dr. Remso, G.m.b.H., Heilgensee. Ger. Pat. 315,371, 20.3.18.

MONAZITE sand is boiled with caustic soda solution, whereby the rare earths are obtained as hydroxides,

and the phosphoric acid is recovered as sodium phosphate.—A. R. P.

Carbide; Process of producing —. J. H. Reid, Newark, N.J., Assignor to International Nitrogen Co. U.S. Pat. 1,327,736, 13.1.20. Appl., 15.3.13.

SEE Eng. Pat. 133,098 of 1918; this J., 1919, 900 A.

Potash-bearing silicate minerals; Process of extracting potassium [compounds] from —. *Process of obtaining combined potassium from minerals.* (A) S. R. Scholes, Beaver, and R. F. Brenner, Rochester, and (B) S. R. Scholes, Assignors to H. C. Fry Glass Co., Rochester, Pa. U.S. Pats. 1,327,781—2, 13.1.20. Appl., 10.5 and 20.8.17.

SEE Eng. Pat. 117,755 of 1917; this J., 1918, 579 A.

Cyanides and nitrides; Method for synthetic production of —. A. R. Lindblad, Stockholm. U.S. Pat. 1,328,575, 20.1.20. Appl., 18.10.18.

SEE Eng. Pat. 119,243 of 1918; this J., 1919, 681 A.

VIII.—GLASS; CERAMICS.

Glassworks furnaces and gas producers; Recent improvements in the designs of —. J. S. Atkinson. J. Soc. Glass Tech., 1919, 3, 148—166.

THE author recommends a Siemens type of open producer with a stepped grate. Water flows along a channel fitted to each grate bar and through slots in the channel, forming a curtain of vapour, some of which enters the producer with the air induced by natural draught. The gas outlet is situated about half-way down the back wall of the producer, and the level of the fuel (coke) is maintained above the top of this outlet. It is claimed that there is a great saving in labour, and that unskilled labour can be used. A pressure gas-producer with automatic feed and a Chapman stirrer is also described. The Stein recuperative glass furnace resembles the Hermansen furnace (this J., 1917, 336) in appearance, but in the former the recuperators are placed on each side, whilst in the latter they are under the furnace, and the air passages in the recuperators of the Stein furnace are vertical instead of horizontal, and there is a constant rise from the point where the air enters to that at which it leaves; this allows a positive flame pressure to be maintained on the hearth of the furnace. In a furnace with 12 covered pots each of 450 kilos. capacity, producing glass for lamp chimneys, the fuel consumption in the Stein furnace was 2000—2500 kilos. per 24 hours or 37—46% of the weight of glass melted, as compared with 65—110% in the Hermansen furnace.

—A. B. S.

[Glass] tank furnaces; Preliminary firing of —. E. E. Fisher. J. Soc. Glass Tech., 1919, 3, 147—148.

THE empty tank should be heated to the highest possible temperature, say 2700° F. (1480° C.), before charging, and maintained at that temperature in order to facilitate the formation of sillimanite and produce resistant tank blocks.

—A. B. S.

Chemical glassware; Investigations on —. C. M. M. Muirhead and W. E. S. Turner. J. Soc. Glass Tech., 1919, 3, 129—131.

AN American soda-zinc borosilicate glass containing SiO₂ 71.03, ZnO 5.30, Na₂O 10.74, and B₂O₃ 7.44%, with small amounts of alumina, lime, iron oxide, magnesia, potash, antimony, and arsenic was tested as previously described (this J., 1918, 692 A). This glass easily falls within the "good" resistance glasses.—A. B. S.

Chemical glassware; Proposals for the standardisation of —. H. Thiene. Z. angew. Chem., 1920, 33, 18—20.

THE author has been commissioned to work out proposals for the standardisation of chemical glassware in Germany, and now puts forward his detailed suggestions for criticism. He proposes that flasks of the same capacity of all types shall have the same width of neck, and would abolish tall conical beakers, round-bottom (not shallow) evaporating dishes, round-bottom flasks with short necks, and all types of Kjeldahl flask except the long-necked, round-bottom variety.—J. K.

Melting point methods. Dana and Foote. See XXIII.

IX.—BUILDING MATERIALS.

Slag bricks. R. Malfait, Rev. Mat. Construction et Trav. Publ., 1919, 123, 335—336.

GRANULATED slag contains a variable, but excessive, proportion of water, some very porous slags containing 60%. After storing under cover for at least a month the water content seldom exceeds 6—12%, and the slag can then be ground readily; the water still remaining effects the hydration of the calcium silicate, and thus forms the chief binding agent in the bricks. Any surplus of water dissolves part of the lime, and tends to disintegrate the bricks. In slag bricks subjected to the action of sea-water or other saline solutions, the most important factor is porosity, the least porous bricks being the most resistant. Greater durability is

secured by addition of colloidal gels such as glue, tannin, etc. The use of pitch as a binder gives still better results. Bricks made of ground slag mixed with finely ground chalk, when immersed for 8 days, gave up 25 grms. to distilled water, 20 grms. to a saturated (0.2%) solution of calcium sulphate, and 15 grms. to a 1% solution of a mixture of sodium, magnesium, and calcium sulphates. 100 grms. of powdered slag brick lost 3.235 grms. in distilled water and 2.560 grms. in calcium sulphate solution, and gained 2.195 grms. in a solution of mixed sulphates. Slag bricks immersed in a 3% solution of common salt for a month lost six to eight times as much as in distilled water, but on a longer immersion no further loss was observed. Although slag bricks are much less porous than those made of clay, they should not usually be employed in situations where they are in contact with sea water.—A. B. S.

Wood; Inaccuracy of treatment tests of impregnated — E. Bateman. *Chem. and Met. Eng.*, 1920, 22, 57—59.

ANALYSIS of wood which has been treated with an inorganic salt preservative seldom shows the same value for the salt absorbed as that calculated from the increase in weight of the treated wood. Blocks of wood in the green, air dried, and oven dried condition respectively were impregnated in a solution of calcium chloride. Concordant results by the two methods were obtained only when the wood was perfectly dry before treatment. Moisture present in wood before treatment acts as a diluent of the preserving solution, and any method of measuring absorption which is based on a measurement of the weight or volume of the solution before and after treatment is liable to considerable error. There is no reason to suppose that any chemical combination results from the treatment of wood with solutions of the usual inorganic salts.—C. A. K.

PATENTS.

Cementing material obtained from greensand. H. W. Charlton, Jones Point, N.Y., Assignor to American Potash Corporation. U.S. Pat. 1,327,145, 6.1.20. Appl., 22.5.17.

A GREENISH- or brownish-white cementing material is made by digesting a mixture of greensand and lime. When freshly made the product is plastic and self-hardening, and it can be still further hardened by treatment with steam.—A. B. S.

Paring and other purposes; Composition for — S. R. Murray, Indianapolis, Ind. U.S. Pat. 1,327,726, 13.1.20. Appl., 1.4.18.

EARTHY materials are ground, heated, mixed with sufficient bituminous cement to lightly coat the particles, cooled, re-ground, heated, and mixed with a further quantity of bituminous cement

—A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast-furnace reactions; Equilibrium in — E. Terres and A. Pongracz. *Z. Elektrochem.*, 1919, 25, 386—407.

THE equilibrium conditions in the reaction $\text{Fe} + \text{CO} \rightleftharpoons \text{FeO} + \text{CO}$ have been investigated by a number of different observers with highly discordant results. The authors have modified the usual procedure for studying such a reaction. Starting with pure iron and carbon dioxide, the reaction was allowed to proceed for seven hours at a definite temperature and the gases were then analysed. The experiment was repeated at a number of temperatures between 550° and 950° C. and

the per cent. CO was plotted against the temperature. A similar set of experiments was made allowing the reaction to proceed for sixteen hours, and in the same way the seven and sixteen hour experiments were repeated, starting from ferrous oxide (prepared by the oxidation of pure iron with carbon dioxide) and carbon monoxide. In this way four graphs were obtained, all of them straight lines and all converging to a point at about 950° C. with about 75% CO in the gas, indicating that in seven hours equilibrium is already attained at this temperature. The two sixteen-hour graphs fell between the two seven-hour graphs and much closer together; they converge at about 810° C., showing that at this temperature complete equilibrium is reached in sixteen hours. The true equilibrium graph evidently lies midway between the two sixteen-hour graphs. It shows no minimum, but is a straight line, confirming the results of Schenck (this J., 1903, 630; 1905, 803; 1907, 692) and Levin (this J., 1912, 926) and contradicting those of Baur and Glaessner (this J., 1903, 699). A number of very careful experiments showed that the composition of the gas phase at equilibrium depends on the quantity of iron used. This can be explained on the assumption that the oxide phase is a mixture or solid solution of two components. Analyses of the solid phase showed that this always contained both ferrous and ferric oxides. The proportion of ferrous to ferric oxide never approached the composition required for Fe_3O_4 . The observations are therefore quite in accordance with the requirements of the phase rule. The fact that the proportion of carbon monoxide in the gas phase increases with the proportion of metallic iron present in the solid phase is of importance in the equilibrium of the blast furnace. It was shown experimentally that the fall in pressure always observed when carbon dioxide and iron are first heated together is due, not to a chemical reaction, but to absorption of the gas by the metal.

For carrying out the analysis of the solid phase a special process was devised. The metallic iron was dissolved out by means of mercuric chloride, which converts the metal into soluble ferrous chloride without attacking the oxides. The ferrous chloride was estimated by titrating with permanganate. The oxides were then dissolved in hydrochloric acid, and in separate portions the ferrous iron was determined by titration with permanganate and the ferric with titanous chloride. As a check, the whole of the iron in the sample already titrated with permanganate was again determined by titration with titanous chloride.—E. H. R.

Iron; Behaviour of — in contact with sulphuric acid. C. E. Fawsitt and A. A. Pain. *J. Proc. Roy. Soc. N.S.W.*, 1918, 52, 396—405. (See also this J., 1914, 231.)

DIFFERENCES in electro-chemical behaviour show that no real similarity exists between iron which is slowly dissolving in concentrated sulphuric acid and iron rendered "passive" by dipping into nitric acid. The action of the acid produces a form of ferrous sulphate monohydrate on the surface of the iron, which causes the slowing down or cessation of the reaction. In general, increasing dilution of the acid with water results in greater reactivity, but certain anomalies were observed in this respect, notably that 89.2% acid had considerably less action on the metal than 91%, 90.9%, 87.9%, or 85% acid. The solvent effect is in all cases noticeably increased by shaking the vessel containing the acid and the metal.—G. F. M.

Zinc ores; Electric resistance furnace for the treatment of — C. H. Fulton. *Amer. Inst. Min. and Met. Eng.*, Sep., 1919. *Chem. and Met. Eng.*, 1920, 22, 73—79.

Oxidised zinc ore, or roasted zinc concentrate, is

mixed with crushed coke and pitch, and formed into briquettes, which are hardened by baking at 400°–500° C. An electric current is then passed through a series of such briquettes, which act as resistors when arranged in columns, and the briquettes are heated to such a degree that the zinc is completely distilled. During the distillation process the briquettes lose 30–50% of their weight, but maintain their shape and volume. When made up with coke and pitch they become practical conductors at 450°–500° C., but if the coke is replaced by a proportion of coal the briquettes do not become conductors until a temperature of 620°–750° C. is reached, and a higher degree of preheating is necessary. The furnace consists of a firebrick base, the central part of which holds the condenser structure. The end portions contain electrode terminals and serve to support the briquette charge and a covering sheet steel retort. The two briquette charges are distilled alternately, and the retort cover is transferred over the one which is being heated. The retort bases and the condenser are heated independently to prevent the formation of "blue powder." A furnace taking 19 briquettes, weighing 600 lb. each, would have a capacity of about 8.5 tons of zinc concentrate per retort per 24 hours.

—C. A. K.

Zinc ores; Electric resistance furnace of large capacity for —. C. H. Fulton. Chem. and Met. Eng., 1920, 22, 130–135.

In operating a zinc-distilling furnace, using briquettes of zinc ore and a reducing material (see preceding abstract), no advantage was secured by replacing the bottom connexion between the retort chamber and the condenser by a similar connecting passage at the top. The condenser consisted of a steel shell lined with "sil-o-cel" brick, with an inner lining of firebrick. A longitudinal partition of firebrick caused a double passage of the gases. The base of the furnace was made of a movable pattern, so that the briquettes might be set in position after pressing, heated to about 500° C., and the whole quickly conveyed to the furnace for distillation, thus conserving the sensible heat of the charge after baking. A higher recovery of zinc is obtained by this method of distillation than by present-day retort processes, and estimated costs show a marked reduction over present costs.

—C. A. K.

Zinc; Recovery of — from low-grade and complex ores. D. A. Lyon and O. C. Ralston. U.S. Bureau of Mines, Bull. 168, 1919. 145 pages.

No technical difficulty exists in the successful flotation of zinc in the slimes from the Joplin district, though units of the size required are not capable of being developed at present. Roasting the mineral at 600°–900° C., in presence of salt, was unsuccessful, as in most cases zinc sulphide was not completely oxidised, and at no time did it seem possible to obtain more than 50% of the zinc in a form soluble in acid brine. For purposes of retort smelting it is important that no sulphur is left in the calcined material, and the chief objection to existing types of furnaces is that when the calcination of the blende is carried to the point of satisfactory elimination of sulphur, the costs of building and operation are very high. On the other hand, the conversion of zinc sulphide into zinc sulphate in the furnace occurs only partially, even at temperatures below that at which zinc sulphate decomposes (630° C.). It has been stated that 30–50% of the zinc is sulphated at Great Falls, Montana, in an Anaconda-Wedge roaster working at about 600° C. Marmatite ores (a double sulphide of iron and zinc) give better results in sulphate roasting than "free" ores, because of the catalytic effect of iron oxide, but a proportion of the zinc is rendered in-

soluble in sulphuric acid by the formation of zinc ferrites. Treatment of a suspension of zinc calcines in water by roaster gases containing sulphur dioxide gives as good an extraction of zinc (as bisulphite) as extraction with sulphuric acid, but it is claimed that the recovery of insoluble zinc sulphate by boiling the bisulphite solution is not complete owing to oxidation of the zinc to zinc sulphate. Chemical methods of precipitating zinc oxide from the solutions obtained by leaching the calcined ore are difficult.—C. A. K.

Chloride volatilisation experiments on ore from Tintic district, Utah, U.S.A. Chem. and Met. Eng., 1920, 22, 52–53.

ALTHOUGH laboratory investigations have almost invariably indicated that an economical recovery of metals which form volatile chlorides should be secured by roasting the mineral with sodium chloride, difficulties have always been encountered during trials on a semi-commercial scale. Laboratory work showed that a volatilisation of 90% of the gold, 91% of the silver, 87% of the lead, and 72% of the zinc could be obtained by muffle scorification of an ore from Eureka, Utah, which contained 62% insoluble matter, 5% CaO, 8% Pb, 2% Zn, and 15 oz. Ag and 0.1 oz. Au per ton. The composition and characteristic properties of this ore are such as to render it unsuitable for treatment by any developed process. Silver chloride, which is practically non-volatile at the temperature of the furnace (850° C.), becomes volatile when lead, sodium, or calcium chlorides are present. Sintering is not favourable to volatilisation, and may be prevented by the addition of lime. The lack of success in large scale trials is attributed to incomplete chloridising and to the difficulty of maintaining a proper temperature and atmosphere in the furnace. Zinc and copper, together with a portion of the lead, can be removed by leaching the fume with water, and gold, silver, and the remainder of the lead are recovered by fusing the residue with lime and coke. (See also preceding abstract.)

—C. A. K.

Copper; Production of — from secondary material. L. Addicks. Chem. and Met. Eng., 1920, 22, 119–122.

MISCELLANEOUS scrap copper-bearing material can always be introduced into the slag cupola, the primary function of which is to treat the anode and bar furnace slags, but little is effected except to concentrate the metals into more convenient shape. Scrap material is usually charged into the anode furnace, which ensures saving any contained silver and gold and getting the copper into electrolytic form. The delay in blowing and skimming caused by the addition of impure material is an objection, and the use of a separate furnace for this class of work might be an economy. By use of a reverberatory furnace having a magnesite bottom and chrome walls and arch, a material free from silver and gold (e.g., brass) can be converted directly into a casting copper. The metallic oxides oxidise in the order of their basicity, and a tin-copper slag, followed by a cobalt-copper slag, may be recovered. Zinc and iron are not of sufficient value to warrant special treatment. Nickel is usually separated as a soluble sulphate during electrolytic refining, and lead may be readily removed from molten copper in the form of litharge, which has been noticed at times to liquate through the furnace bottom.

—C. A. K.

Metals and alloys; Reports of the sub-committee for the standardisation of —. Doerinczel, Philippi, Bauer, and E. H. Schulz. Metall u. Erz, 1919, 16, 591–600.

Four reports are presented, dealing with the

nomenclature and the amount of permissible impurities in brasses, bronzes, and other copper alloys; and also a table showing the properties of the more important brasses and two tabulated schemes for the standardisation of brasses and bronzes showing the limiting amount of impurity allowable in many commercial alloys. The recommendations as to the naming of the alloys are substantially the same as those put forward by the Institute of Metals Committee (this J., 1914, 318).

—A. R. P.

Copper-antimony alloys; Expansion of —. P. Braesco. *Comptes rend.*, 1920, 170, 103—105.

THE mean coefficient of expansion between 100° and 300° C. of copper-antimony alloys increases with the percentage of antimony present up to 38.6% Sb, and then diminishes, the differences between the results with quenched and annealed alloys being only very slight. Certain alloys within the range 4 to 50% Sb show for a given temperature a considerable increase in volume, with increase in the antimony contents. Here, again, the maximum is reached at 38.6% Sb, and then rapidly drops to zero at 50% Sb. The maximum point in both cases corresponds to the definite compound Cu_3Sb .

—W. G.

Bismuth, tin, and wolfram ores; Treatment of —. W. E. Hitchcock and J. R. Pound. *Proc. Austral. Inst. Min. and Met.*, 1919, [35], 33—73.

A DETAILED account of the methods employed in mining, milling, and magnetic separation of tin, bismuth, and tungsten ores is given. After hand picking of the ore both before and after breaking the rock, the material is further reduced between rolls, and passes over jigs of the Hartz type. The overflow from the hydraulic classifiers passes to two Rittingen classifiers, and is fed on to Wilfley tables, from which the concentrates are treated in a buddle. All concentrates are dried and divided into four sizes by screening, each size being treated separately on a Wetherill magnetic separator. For economic handling the ore must be fed evenly on to the conveying belt and the full effect of the magnetic field utilised by bringing the magnets as close to the ore as possible. The speed of the cross belts should carry the particles clear of the magnetic field; a speed of about 300 ft. per min. is usually sufficient. This type of machine is not suitable for the treatment of slimes, and the best size of material is that "minus 10 and plus 20 mesh," averaging 0.04 in. diameter. The "seconds" concentrates yield after magnetic separation pyritic wolfram and pyritic tin-bismuth products, and these are roasted separately to convert the pyrites into magnetic iron sulphide or oxide. A further magnetic separation follows. The grade of the lower class concentrates is raised by separating the magnetic minerals (e.g., ilmenite, chromite, magnetite), and the tin is obtained along with the other non-magnetic minerals, such as quartz, zircon, and non-magnetic spinel.—C. A. K.

Wulfenite; its concentration and separation from barite. J. P. Bonardi. *J. Franklin Inst.*, 1920, 189, 47—61.

A RESUME is given of the occurrence in America of molybdenum ores, tests for molybdenum, methods for its quantitative estimation in ores, the properties of wulfenite, and the ordinary methods of concentration of the more commonly occurring wulfenite ores. This is followed by a detailed description of laboratory experiments on a "middling" material containing 52.2% barite and 5.50% molybdenum as wulfenite, along with quartz and some lead-containing minerals—mimetite, pyromorphite, vanadinite, etc. The original ore contained about 2% of molybdenum and was concentrated on a

Wilfley table, leaving the middling product experimented on. The ore was examined microscopically and subjected to screening, Wilfley table, and flotation tests, tabulated results being given. The flotation test, after a sulphiding treatment with sodium sulphide, showed little or no separation of the wulfenite from the barite owing to the presence of iron, and some of the wulfenite was lost by solution in the sulphiding liquor. The Wilfley table method gave a concentrate with 14% molybdenum and a recovery of from 60 to 70%.—B. V. S.

Molybdenum; Reversible reaction of water on —. G. Chaudron. *Comptes rend.*, 1920, 170, 182—185.

A STUDY of the system water vapour, molybdenum, hydrogen, molybdenum dioxide over the temperature range 700°—1100° C. The values of $K = p_{\text{H}_2\text{O}}/p_{\text{H}_2}$, obtained by the oxidation of the metal or the reduction of the oxide are in close agreement.—W. G.

Iron and steel; Process and ladle for the decaridation of — by means of calcium carbide. Röchlingsche Eisen- und Stahlwerke G.m.b.H., and W. Rodenhäuser, Völklingen. Ger. Pat. 298,847, 31.5.16.

MOLTEN calcium carbide is added to the metal bath from a ladle, the lining of which consists of carbon or a mixture of carbon and other refractory, the ladle being preheated electrically to prevent chilling of the carbide.—A. R. P.

Blast furnace gases; Apparatus relating to the cooling of —. J. E. Weyman, Newcastle-upon-Tyne. Eng. Pat. 137,378, 16.1.19. (Appl. 1150/19.)

INCREASED efficiency of cooling is obtained by using a forced circulation of the cooling water. The top box of the economiser is divided vertically in halves. Pipes extend from the top box vertically downwards, each pipe being divided by a partition which extends almost to the bottom of the pipe. The cooling liquid passes along one side of the top box and down half of each of the pipes attached to it, and up the other half to the other side of the top box. The pipes are circular in section to allow of the use of scraping gear and scrapers in the usual manner.—W. P.

Electric furnace; Arc-type — [for melting metals] and method of operating same. W. E. Moore, Assignor to Pittsburgh Engineering Works, Pittsburgh, Pa. U.S. Pat. 1,326,083, 23.12.19. Appl. 30.7.17.

METAL is melted in an electric furnace of the arc type, provided with a number of electrodes, by effecting a short-circuit or contact between the charge and one of the electrodes, whilst maintaining an arc between the charge and another of the electrodes; subsequently an arc is formed between the electrode, previously short-circuited, and the charge.—B. N.

Ores; Process and apparatus for extracting [roasting] —. R. Wallner, Bisbee, Ariz. U.S. Pat. 1,326,125, 23.12.19. Appl., 20.10.17.

ORE is roasted in a rotating retort which is heated externally, and through which fresh air is forced in opposite directions alternately.—W. E. F. P.

Fine-grained ores; Process for smelting — by introducing them into the blast furnace by means of the blast. O. Baumann, Amberg. Ger. Pat. 314,777, 3.2.18.

IN working the process described in Ger. Pat. 312,935 (this J., 1920, 70 A) the blast-furnace shaft is fed with nearly spherical lumps of limestone and coarse ore and fired with pulverised coal or combustible furnace gases blown into the tuyères together with fine-grained ore. Each tuyère is provided with a valve which regulates the amount of dust carried according to the volume of the blast. The shaft may be provided with an upper row of tuyères, through which air is introduced, whereby the gases are converted into carbon dioxide and the coarse ore is roasted in the shaft. The production of steel in the blast-furnace by this method is claimed without the intermediate production of pig-iron rich in carbon.—A. R. P.

Acid or like baths for treating wire. Oates and Green, Ltd., and C. H. Ashton, Halifax. Eng. Pat. 137,414, 25.2.19. (Appl. 4665/19.)

PATENTS.

Electrical separation of substances in suspension in gaseous media; Apparatus for the —. Soc. Gallet et Cie., Paris, and Soc. Poussin Rondeaux et Cie., Pantin, France. Eng. Pat. 116,104, 22.5.18. (Appl. 8529/18.) Int. Conv., 22.5.17.

AN apparatus for the electrical separation of materials in suspension in a gas comprises a perforated or non-perforated tubular electrode, with a wire along the longitudinal axis forming the second electrode and stretched and supported on insulators mounted in attached chambers. The gas inlet is arranged some distance above the insulator chamber, so as to create an electrical protecting zone consisting of a portion of the tubular electrode in which no dust is deposited. In an alternative form the gas inlet opens into the tubular electrode at about the middle of its length, the gas escaping from both ends, or in a further form an electrical protecting zone is formed by an auxiliary tubular electrode of reduced length carried by the insulator chamber.—B. N.

Electrical purification of hot, dust-laden gases; Collecting electrodes for the —. H. Püning, Münster. Ger. Pat. 314,030, 26.6.18.

THE electrodes are composed of refractory material containing alumina, magnesia, and silica, such as porcelain, firebrick, or like materials. With rise of temperature the conductivity of the electrodes increases. By the use of such electrodes gas may be freed from dust without the necessity of lowering its temperature.—J. S. G. T.

Electrodes for electro-osmotic processes. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Eng. Pat. 135,816, 25.6.18. (Appl. 10,454/18.) Int. Conv., 20.10.17.

Two perforated sheets are connected together by means of distance pieces or by a corrugated sheet so as to form a grate-like carrier, on each side of which a wire fabric is fixed which is easily disconnected; or several wire fabrics of different degrees of fineness may be arranged one above the other on the two sides of the carrier.—B. N.

Electric furnaces. T. H. Watson and Co. (of Sheffield), Ltd., H. A. Greaves, H. Etchells, and W. Travis, Sheffield. Eng. Pat. 136,960, 21.2.19. (Appl. 4320/19.)

A HEARTH or lining, consisting of a layer of electrically conductive broken chromite, is employed in electric furnaces in contact with the metallic connections, and this is surmounted or adjoined by a ramming of silicious material mixed with tar or pitch, with or without finely-divided metal. The upper lining is of a depth sufficient to keep the bath of metal from contact with the chromite or other electrically conductive material employed.—B. N.

Induction-furnace. M. Unger, Pittsfield, Mass., Assignor to General Electric Co. U.S. Pat. 1,326,120, 23.12.19. Appl., 21.4.19.

THE furnace has a melting chamber the side walls of which are inclined outwards from each other at an angle of 60°—90°.—W. E. F. P.

Electric arc furnaces; Method of fixing electrodes in —. Ges. für Elektrostablanlagen m.b.H., Berlin, and W. Rodenhauer, Völklingen. Ger. Pat. 314,884, 27.10.17.

THE frame for making contact with the electrode surrounds the latter, and is angular or U-shaped in section. Below the frame and insulated therefrom is a ring gripping the electrode tightly and forming a support. There is considerable space between the frame and the electrode, and this space, together with that intervening between the ring and the frame, is tightly packed with compressed material containing much carbon.—J. S. G. T.

Battery-plate envelope. C. C. Carpenter, Assignor to U.S. Light and Heat Corporation, Niagara Falls, N.Y. U.S. Pat. 1,325,710, 23.12.19. Appl., 16.4.13. Renewed 8.5.19.

A BATTERY plate is protected by slotting it from one edge to a point adjacent to the opposite edge and enclosing it in alternate "punchings" of soft rubber having integral projections passing through the slots, and strips of metallic zinc arranged in planes at right angles to the surface of the plate. The open ends of the slots are closed and the soft rubber vulcanised to provide a hard rubber envelope, the plate being afterwards treated in an acid bath to dissolve the zinc.—B. N.

Electrode for electrolytic apparatus. R. D. Mershon, New York. U.S. Pat. 1,326,134, 23.12.19. Appl., 2.4.17.

AN electrode for electrolytic apparatus comprises a

crimped or folded plate of sheet metal having apertures in the bends of the crimps or folds.—B. N.

Electrolyte for electrolytic condensers. J. Slepian, Pittsburgh, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,326,297, 30.12.19. Appl., 16.1.19.

An electrolyte for condensers, lightning arresters, rectifiers, and the like comprises an aqueous solution of an alkaline-earth aluminate.—B. N.

Selenium cells; Process for the manufacture of —. O. Hannach, Berlin-Wilmersdorf, and H. Böcker und Co., Berlin. Ger. Pat. 304,261, 14.10.16.

Amorphous selenium is treated with a solution of quinoline, silver is added, and the mixture heated to about 200° C. The mixture is then cooled extremely slowly, say, over a period of from two to three days. Selenium cells constructed of the resulting product are extremely sensitive to light.

—J. S. G. T.

Electrolyte for high temperature combustion electric cells. Siemens und Halske A.-G., Siemensstadt. Ger. Pat. 308,585, 29.3.18.

In place of an electrolyte which is liquid at the working temperature of the cell an electrolyte of the nature of an enamel is employed, which is an electrolytic conductor, is impermeable to gas, and has a coefficient of expansion as nearly as possible the same as that of the metallic electrodes. The enamel is composed essentially of a fused mixture of an alkaline basis such as borax, alkali phosphate or silicate, alkalis or alkali carbonates, together with one or more metallic oxides, these latter being more or less conductors of the second class at ordinary temperatures, but conducting electrolytically at higher temperatures. The oxides of manganese, chromium, iron, vanadium, uranium, etc., may be employed for this purpose. Alternatively the enamel may be constituted of definite compounds of the alkalis and oxides, e.g., sodium ferate, sodium vanadate, or mixtures of such compounds. The enamel is fused, then powdered and employed as an electrolyte in the usual manner. As the enamel is impermeable to gas even in very thin layers, the combustion cell can be constructed so as to possess a very low internal resistance.

—J. S. G. T.

Depolarising agents employed in electric batteries. W. Keil, Berlin. Ger. Pat. 309,242, 16.7.15.

Soot is added to the customary depolarisers. The soot should be free from tarry and greasy matter, and if necessary these are removed by means of alkalis, acids or heat.—J. S. G. T.

Separator; Wooden — [for electric cells]. M. Löffler, Soest. Ger. Pat. 314,723, 27.7.17.

The separator is made of wood which has been immersed in, or treated with, a salt solution so that on subsequent drying crystals of salt are deposited in the pores of the wood. Shrinkage on drying is prevented, and wood so treated can be stored for any length of time. When the wood is brought into contact with acid in an electric cell the salt is removed either in whole or in part or converted into a harmless compound. The separator possesses an extremely high porosity, as the pores of the wood are neither constricted nor choked.—J. S. G. T.

Electric furnaces; Control of power absorbed in —. C. C. Gow and D. F. Campbell, London. U.S. Pat. 1,327,548, 6.1.20. Appl., 24.4.19.

Electric furnace. U.S. Pat. 1,326,083. See X.

XII.—FATS; OILS; WAXES.

Linseed oil; New hexabromide method for —. L. L. Steele and F. M. Washburn. J. Ind. Eng. Chem., 1920, 12, 52—59.

HEHNER and Mitchell's method of determining the amount of linolenic hexabromide yielded by the fatty acids of linseed oil has been modified by effecting the bromination in a solvent in which the hexabromide is soluble (e.g., chloroform), removing the excess of bromine by the addition of a reagent (amylene), separating the hexabromide and washing it thoroughly with ether previously saturated with hexabromide. The amount of hexabromide thus separated from the fatty acids of seven different samples of linseed oil ranged from 45.6 to 46.6%, duplicate determinations agreeing within about 0.5%. Apparently, therefore, the yield of hexabromide is a more constant value than the iodine value of raw linseed oil. Cottonseed and tung oil fatty acids gave no precipitate, whilst a sample of soya bean oil yielded 2.2%. Experiments with mixtures indicated that it may be possible to detect 5% of oils low in hexabromide yield in linseed oil by this method.—C. A. M.

Squalene: a highly unsaturated hydrocarbon in shark liver oil. M. Tsujimoto. J. Ind. Eng. Chem., 1920, 12, 63—72. (See also this J., 1916, 609, 1121.)

SQUALENE is of most frequent occurrence in the liver oils of the *Squalidae*, but is also found in considerable amount in the oils of several other species, including the frill shark and hasking shark (*Cetorhinidae*). For the approximate quantitative separation of hydrocarbons, including squalene, in shark liver oils 50 grms. of the oil is distilled under a reduced pressure of about 10 mm., and in a current of carbon dioxide or other indifferent gas. The acid value of the distillate is calculated into oleic acid and deducted from the weight of the distillate, the difference giving the approximate quantity (within about 1.6%) of hydrocarbons. Squalene obtained from aizamé shark oil had sp. gr. 0.8591 at 15°/4° C., and 0.8559 at 20°/4° C. In the Livache test it absorbed oxygen very slowly after the first three days, but the amount became nearly constant (24.3%) in 23 to 28 days. The oxygen absorption calculated from the formula $C_{30}H_{50}O_4$ was 23.66%. On debrominating the dodecubromide, $C_{30}H_{14}Br_{12}$, an oily liquid with refractive index 1.4950 at 20° C. was obtained. The formation of the characteristic hexahydrochloride is the most distinctive test for squalene (this J., 1918, 312 A). The hexabromide forms white lustrous crystals which turn brown at 115°—118° C. and melt to a brown liquid at 125°—126° C. Although the hydrocarbon "spinacene" isolated by Chapman from Portuguese shark liver oils (this J., 1917, 392, 602) differs slightly in some of its physical characters from squalene, it seems probable that the two hydrocarbons are identical. (See also J. Chem. Soc., March, 1920.)—C. A. M.

Squalene; Occurrence of — in the egg oil from a shark. M. Tsujimoto. J. Ind. Eng. Chem., 1920, 12, 73.

THE oil separated from the eggs of the Japanese shark *Lepidorkhinus kinbei* (Tanaka) was a light brown substance, which was mainly solid at the ordinary temperature. It had the following characters:—Sp. gr. at 15° C., 0.8997; acid value, 31.3; saponif. value, 107.0; iodine value (Wijs), 177.6; refr. index (20° C.), 1.4769; and unsaponifiable matter, 33.0%. When treated with dry hydrogen chloride in ethereal solution it yielded 20% of a white crystalline precipitate (m. pt. 123°—124° C.), which was identified as squalene hexahydrochloride.

Squalene has also been separated from the egg oil of the frill shark, *Chlamydoselachus anguineus*.

—C. A. M.

Mountain elder (Sambucus racemosa); Fatty oil from the berries of —. H. Thoms. Ber. dents. Pharm. Ges., 1919, 29, 598—627.

The seeds of the berries of the mountain elder (*Sambucus racemosa*, L.) yielded on hot expression 50% of a drying oil consisting essentially of the glycerides of linolic, linolenic, and oleic acids, and possibly of isolinolenic acid, together with some palmitic and stearic acids. Eight samples of the oil of different origin had the following characters: Sp. gr. 0.9242—0.9439 at 21° C.; n_D^{20} (1 sample) = 1.47967; acid value, 3.07—29.24; saponif. value, 186.9—198.1; and iodine value, 156.3—177.4. The fruit oil differed materially in character, a sample giving:—Sp. gr. 0.9214 at 21° C.; solidification pt., -4° C.; acid value, 5.59; saponif. value, 196.5; and iodine value, 98.6. The oil has toxic properties, which, however, can be removed by heating it to 200° C.—C. A. M.

Fat extraction apparatus. Pickel. See XXIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Colophony; Autorization of —. L. Paul. Koloid Zeits., 1919, 25, 241—246.

When a solution of colophony in alkali is treated with hydrochloric acid a voluminous precipitate of γ -pinic acid is obtained; this substance melts at 75°—76° C. when freshly prepared, but in eight months the melting point rises to 88° C. α -Pinic acid has a constant melting point, 81°—83° C., and shows a tendency to form liquid crystals. It is soluble in water and petroleum as also is γ -pinic acid. β -Pinic acid melts at 98°—100° C.—J. F. S.

Resins from Cochín China; Characteristics of some —. P. Nicolardot and C. Coffignier. Bull. Soc. Chim., 1920, 27, 71—74.

TEN specimens of resins from different sources have been examined. They closely resemble one another, are of the soft type and of no special interest for the manufacture of varnishes. Their characteristics, sp. gr., m. pt., and acid and saponification values are tabulated. None of these resins was completely soluble in N/2 alcoholic potassium hydroxide; and in every case the alcoholic solution gave either a milkiness or a precipitate on the addition of water.—W. G.

Abietic acid. D. Johansson. Arkiv Kem., Min., Geol., 1917, 6, No. 19.

ABIETIC acid is reduced by hydrogen in presence of platinum black to dihydroabietic acid, $C_{20}H_{32}O_2$, m.pt. 173°—178° C., but this compound gives approximately the same Hübl-Waller and Winkler iodine values as the parent acid. Further, the values increase with the duration of the reaction, and similar relationships are shown by *d*-pimaric acid and its dihydro derivative. It is, therefore, suggested that the unreduced acids contain at least two non-equivalent double bonds, or that substitution by iodine also occurs. No derivatives of this type could, however, be isolated. The author considers the presence of an aromatic or hydroaromatic nucleus in the molecule of abietic acid to be now definitely established (compare Easterfield and Bagley, this J., 1904, 989). (See further, J. Chem. Soc., March, 1920.)—J. K.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Synthetic —. H. P. Stevens. Bull. Rubber Growers' Assoc., 1919, 1, [3], 55—56.

TWO samples of German synthetic rubber, one consisting of a colourless transparent slab and the other of an opaque reddish-brown crêpe, were found to be free from fatty oils and "substitutes." The materials, which yielded respectively 473% and 437% on extraction with acetone and refused to dissolve in benzene although they swelled considerably, were difficult to work into smooth sheet and vulcanised much more slowly than natural rubber.

—D. F. T.

Rubber from matured coagulum (slab); Uniformity of —. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, [1], 68—71.

THE statement of Eaton and Grantham as to the remarkable uniformity of "slab" rubber is not justified. (See also de Vries, this J., 1918, 664 A.)

—D. F. T.

[*Rubber*] *latex coagulant; Synthetic acetic acid as a —*. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, [1], 71.

A SAMPLE of synthetic acetic acid prepared from acetylene, when applied as a coagulant, gave results identical with those observed with acetic acid produced from pyroligneous acid.—D. F. T.

[*Rubber*;] *Effect of varying proportions of acid in coagulation on the rate of cure [of —]*. H. P. Stevens. Bull. Rubber Growers' Assoc., 1919, 1, [1], 39—41.

THE observation of other investigators to the effect that an increase in the proportion of acetic acid causes a decrease in the rate of vulcanisation of the resulting rubber, is confirmed. The effect is a little more marked with smoked sheet than with air-dried crêpe and is still more marked for crêpe prepared from matured "slab" rubber. (See also de Vries, this J., 1917, 1140; Campbell, this J., 1917, 604.) —D. F. T.

[*Rubber*;] *Effect of exposure to air on maturation [of —]*. H. P. Stevens. Bull. Rubber Growers' Assoc., 1919, 1, [2], 42—44.

EXPOSURE to air during maturation does not appear to have any very marked effect on the rate of vulcanisation of the finished rubber, but open maturing generally produces a slightly faster curing rubber than maturing in closed vessels.—D. F. T.

Metrolac [for determining rubber content of latex]. H. P. Stevens. Bull. Rubber Growers' Assoc., 1919, 1, [2], 44—45.

ALTHOUGH the Metrolac cannot be relied on to give accurate results for the rubber content of an individual sample of latex, it is nevertheless useful for standardising bulked latex and for estimating the yields of rubber on an estate. In its application to the latter purpose the errors over a period tend to eliminate themselves by compensation. (See also de Vries, this J., 1919, 590 A.)—D. F. T.

[*Rubber*;] *Reactions of accelerators during the vulcanisation [of —]*. C. W. Bedford and W. Scott. J. Ind. Eng. Chem., 1920, 12, 31—33.

THE most active accelerators of the vulcanisation of rubber are products of the reaction of carbon bisulphide with strong organic bases, such as the piperidine salt of piperidyl-dithiocarbamic acid. Thiocarbamilide is produced by a similar reaction. The stable metallic dithiocarbamates lose hydrogen sulphide when heated to the temperature used in the vulcanisation of rubber, and form thiourea derivatives, so that they may act in the same way as thiocarbamilide in the process. The main reaction of accelerators containing methylene groups (methylene-aniline, methylene-diphenyldiamine) appears to be to substitute thiocarbonyl groups for the methylene groups, and the resulting compounds may be regarded as thiocarbamilide derivatives. The accelerating action of hexamethylenetetramine may be attributed to the formation of a dithiocarbamate. Apparently all accelerators of this type containing methylene groups react readily with sulphur to form thiourea derivatives, but this does not apply to the methylene groups in such compounds as piperidine, or pentamethylenediamine, which when heated loses ammonia and forms piperidine.—C. A. M.

Rubber compounds, Expansion of — during vulcanisation. C. W. Sanderson. J. Ind. Eng. Chem., 1920, 12, 37—40.

AN apparatus for testing the amount of expansion of rubber when exposed to heat, consists essentially of a hollow steel cylinder 2 in. high and 0.7978 in. in diameter, which may be filled with the rubber, and which is surrounded by a steam jacket. When the rubber expands on heating, its top surface acts

against a piston and spring which transmit the motion through a magnifying lever to a recording pencil. Above the piston is fixed a spring to maintain sufficient pressure upon the rubber to prevent it from "blowing." The rubber is heated at a constant rate, usually 20° C. per 5 mins., and the recording cylinder moved forward at each interval. The results, when plotted in curves, afford a means of distinguishing between different batches of the same stock, which may have contained different rubber or have been subjected to varying conditions of milling, etc. The summarised results indicated that the higher the rubber content the greater the expansion, and that the harder the crude rubber the less the expansion. The expansion increases with the amount of milling, whilst there is no break in the expansion at the point of vulcanisation. The increase in the sp. gr. is due to the pressure, and not to physical change or internal contraction of volume.—C. A. M.

Rubber; Increase in the volume of compounded — under strain. H. F. Schippel. J. Ind. Eng. Chem., 1920, 12, 33—37.

WHEN rubber containing a pigment is stretched it will separate from the pigment particles, causing spaces to be formed on each side of the latter, and thus producing a considerable increase in the total volume of rubber. The effect of stretching upon rubber containing various percentages (by vol.) of barytes, whiting, zinc oxide, china clay, red oxide, lampblack, and carbon black was determined by stretching test rings of the rubber upon a graduated series of steel bars and calculating the increase in vol. from the change in the sp. gr. of the material. It was found that the greater the mean diameter of the pigment particles the greater was the increase in volume under strain. In certain cases the increases under strain were very pronounced. For example, a sample containing 100 grms. of fine Para rubber, 30 grms. of litharge, 5 grms. of sulphur, and 337 grms. of whiting, which had been cured for 30 mins. at 40 lb. steam pressure, showed a volume increase of 52% at an elongation of 140%. —C. A. M.

PATENT.

Rubber; Testing device for determining the "viscosity" of —. R. B. Naylor, Springfield, Mass., Assignor to The Fisk Rubber Co., Chicopee Falls, Mass. U.S. Pat. 1,327,838, 13.1.20. Appl., 5.2.19.

THE test piece of rubber is held by two grips which can be rotated independently about an axis perpendicular to the general plane of the gripping surfaces; arrangement is made for the application of known pressure and torsional force between the grips and for the indication of the resulting relative rotation.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

PATENTS.

Iron-tanned leather; Preparation of tough and durable —. K. W. Mensing, Freiberg, Ger. Pat. 314,885, 2.2.16. Addn. to Ger. Pat. 314,187.

IN the tanning process by use of iron salts, described in the chief patent (this J., 1920, 121 A), the removal of the excess of iron salts as well as the treatment with alkalis may be carried out before drying or oiling the leather. The iron-tanning process may be followed by treatment with solutions of vegetable or similar tanning agents. It may also be followed by treatment with reducing agents, if necessary after treatment with dilute acid solution. In this latter case there is partial re-

removal of iron salts from the outer layers, resulting in bleaching and allowing milder "grain" to be obtained.—B. V. S.

Tanning extract; Process of the production of — from waste sulphite lye. H. B. Landmark, Drammen, Norway. U.S. Pat. 1,327,105, 6.1.20. Appl., 23.4.15.

SEE Fr. Pat. 474,336 of 1914; this J., 1915, 1105.

Cattle food [from tannery offal]. Ger. Pat. 314,957. See XIXA.

XVI.—SOILS; FERTILISERS.

Soil acidity. II. Its relation to the acidity of the plant juice. E. Truog and M. R. Meacham. Soil Sci., 1919, 7, 469—474.

THERE is considerable variation in the acidity of the juices of different species of plants, but for each particular species the acidity is usually limited to a rather narrow range, there being, in all probability, a certain acidity which is most favourable for the life processes of that species. In many cases soil acidity, by limiting the supply of lime available for the plants, affects the acidity of the juice or protoplasm of the plants. In addition to the soil conditions, weather conditions, lapse of time after cutting the plant, and the time of the day at which the plant is cut affect the acidity of the plant juice. There is a slight difference in acidity between the juice of the tops and of the roots of plants.—W. G.

Soil acids; Activity of —. R. E. Stephenson. Soil Sci., 1919, 8, 41—59.

USING a modification of Tacke's method (this J., 1918, 776A), the author has endeavoured to arrive at the degree of activity of the soil acids, the lime requirements being determined for the given soil by measurements after 3, 6, 9, and in some cases 23 hours' contact between the soil and the calcium carbonate. The results show that soil acidity may be divided into two parts, viz., that produced by the more reactive acids, which are capable of giving a toxic hydrogen-ion concentration; and that which may be described as potential rather than active, this acidity being capable, however, of slowly decomposing carbonates. Protein substances and amino-acids, so far as tested, previous to decomposition in the soil, do not react readily with carbonates. It is necessary to know something of the activity of the soil acids, as well as of the total potential acidity, commonly determined more or less inaccurately. It is not the capacity of a soil to decompose lime, but rather the intensity of decomposition which is most highly significant. (See further J. Chem. Soc., Mar., 1920.)—W. G.

Acid soils and the toxicity of manganese. M. J. Funchess. Soil Sci., 1919, 8, 69.

THE toxicity of certain plots on the Alabama Agricultural Experiment Station farm was ascribed to the presence of soluble manganese. From further studies of these soils the author now considers that that conclusion is untenable.—W. G.

Soya beans; Effect of inoculation and lime on the yield and on the amount of nitrogen in — on acid soil. E. B. Fred and E. J. Graul. Soil Sci., 1919, 7, 455—467.

INOCULATION of soya beans grown on an acid sand increased the yield of dry matter of the tops, the yield being further increased when inoculation was supplemented by an application of lime. An application of lime just sufficient to neutralise half the active soil acidity gave the maximum yield.

Similarly the nitrogen content of the crops was considerably increased by inoculation, due to greater fixation of atmospheric nitrogen.—W. G.

Vegetative growth in soils containing crude petroleum. R. H. Carr. Soil Sci., 1919, 8, 67—68.

THE growth of soya beans was apparently improved by the addition of small amounts of oil, up to 13,400 lb. per acre, but further additions beyond this point caused a diminution in the growth until with about 72,000 lb. of oil per acre the plant practically succumbed to the treatment. The damage seems to be due in part to the plant's inability to secure water rapidly enough to meet its needs.—W. G.

Plant growth; Effect of nitrogen-fixing organisms and nucleic acid derivatives on —. W. B. Bottomley. Proc. Roy. Soc., 1920, 91B, 83—95.

PREVIOUS work (this J., 1917, 728) having shown that a water extract of bacterised peat had remarkable stimulative properties on the growth of *Lemna minor* in water cultures, further experiments were made with the individual constituents of the water extract. A pure growth of *Azotobacter chroococcum* was sterilised in the autoclave in presence of water and added in small known amounts to *Lemna minor* plants in Detmer's nutritive solution. In six weeks there was recorded an increase in rate of growth and in dry weight of the crop over untreated plants. A similar result was obtained with *B. radiclecola*. An extract of the crude nucleic acid derivatives and of the adenine-uracil fraction from raw peat (see this J., 1917, 1143) stimulated growth also. When the extract of crude nucleic acid derivatives was added along with the growth of *Azotobacter chroococcum* to the same plants, the growth produced exceeded that of the total of the effects of the two constituents taken separately, showing that the stimulating constituents in the extract of peat differed from those in *Azotobacter chroococcum*. The ash of the nucleic acid derivatives and the ash of *Azotobacter chroococcum* had no stimulative effect.—J. H. J.

Nitrolim; Attempts to obtain — free from dust. N. Caro. Chem.-Zeit., 1920, 44, 53—56.

MUCH attention has been devoted towards obtaining nitrolim free from dust and without its caustic qualities, these drawbacks being due to the presence of unconverted carbide and free lime. Addition of water as a binding agent is unsatisfactory; although the carbide certainly undergoes decomposition, yet the lime, being in a "dead" condition, remains practically unchanged, and further the water itself causes decomposition of the cyanamide. Most of the remedies suggested, such as addition of colloids, or chloride of calcium or magnesium, are unsuitable inasmuch as they require water as a vehicle. If the amount of water added is much reduced, decomposition will not take place, but the binding qualities will not be permanent. Addition of the water in the form of crystalline salts led to no good results, nor did mechanical treatment of the mass by sieving or pressing after mixing with water prove effective. As a binding agent, paraffin oil gives most favourable results; it is essential that phenols should be absent, as these deleteriously affect the fertilising power of the nitrolim. To neutralise the caustic action of the product, sugar or sugar-containing solutions derived from molasses or cellulose manufacture may be added. The sugar combines with the lime to form saccharates, and fulfils a three-fold purpose inasmuch as it also acts as a binding agent for the dust, and aids the action of the fertiliser by development of bacteria. The water which is introduced with the sugar solution is to a large extent retained by the colloidal matter

present and its effect on the nitrolim is very slight. The admixture of nitrolim with other fertilisers is not industrially practicable as the mixtures are either too low in nitrogen content or are unstable.—W. J. W.

Seeds; Report on the proposed electrolytic treatment of — [Wolfryn process] before sowing. E. J. Russell. J. Ministry Agric., 1920, 26, 971—981.

For experiments were made with oat and barley seeds which had been treated by the Wolfryn electrolytic process (this J., 1914, 1067) and with similar untreated seeds. The weights of the crops produced varied very much, there being sometimes a gain and sometimes a loss resulting from the electrolytic treatment. In further similar trials, the majority of the results showed a loss or no improvement in the crops from the treated seeds. In field experiments also negative results were obtained, except in a few cases where seed was sown after roots had been fed off. It is concluded that the process is an uncertain one, which may or may not succeed in any given case.—J. H. J.

Plant juices. Haas. See XIX A.

Oxidation of vanillin by soil bacterin. Robbins and Lathrop. See XX.

PATENTS.

Fertiliser and method of producing the same. P. Radmann, Stockholm. Eng. Pat. 137,171, 5.3.19. (Appl. 5477/19.)

A MIXTURE of felspar, gypsum, and limestone is heated to 1000°—1250° C. (see Eng. Pat. 12,136 of 1914; this J., 1915, 138), and the product is disintegrated in a jaw crusher, ground in a ball mill, and used directly as a fertiliser. Up to 60% of calcium phosphate in the form of apatite or other mineral phosphate may be added to the mixture before heating.—J. H. J.

[Calcium] cyanamide containing free lime; *Process of granulating —.* V. Thrane, Christiania, Norway. U.S. Pat. 1,326,310, 30.12.19. Appl., 16.1.17.

CALCIUM cyanamide containing free lime is mixed with water and fed on to a moving surface, where it is pressed to accelerate the reaction between the lime and water. It is pressed again and dried, still on the moving surface, and is then broken up into granules.—J. H. J.

Dicalcium phosphate; Process of making — and fertiliser material produced therein. S. S. Sadtler, Springfield township, Pa. U.S. Pat. 1,326,533, 30.12.19. Appl., 10.3.19.

COMMUNUTED phosphate rock is subjected to the action of sulphur dioxide and steam at 100° C. The product contains dicalcium phosphate, monocalcium phosphate, and calcium sulphite, and is free from acid.—J. H. J.

Fertiliser; Process for the preparation of a stable, mixed — which can be easily distributed. F. Dahl, Hamborn-Bruckhausen. Ger. Pat. 314,404, 20.6.17.

AFTER neutralisation of the free lime in a mixture of an ammonium salt solution and ground basic slag, a sodium or potassium salt, or a mixture of both, is added immediately, with constant stirring. —A. R. P.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Balance of nitrogen during the manufacture of —. Precipitation of the proteid matter of the beetroot by sulphurous acid, bisulphites, and hydrosulphites. E. Saillard. Comptes rend., 1920, 170, 129—130.

IN sugar factories which distil their molasses and burn their vinasses the nitrogen of the beetroot is distributed in the following proportions: In the carbonatation cake, 15%; in the fodder pulp, 20%; in the press waters, 18%; liberated as ammonium during the processes, 17%; liberated during the incineration of the vinasses, 30%. Sulphurous acid and its compounds precipitate from sound beet-roots the same polarising substances as does basic lead acetate. They also precipitate as much proteid material from the juice as do copper hydroxide and aluminium sulphate when used together.—W. G.

Sucrose; Cryoscopic method for the determination of —. H. H. Dixon and T. G. Mason. Scient. Proc. Roy. Dublin Soc., 1920, 16, No. 1, 1—8.

A METHOD for the determination of sucrose in small volumes of liquid is based on the fact that after inversion the depression of freezing point of a sucrose solution is approximately doubled. Invertase is added to the sap or other liquid in the cold and the freezing point determined, after which the mixture is incubated at 30° C. for 48 hours and a second observation made. A differential thermoelectric device (Scient. Proc. Roy. Dublin Soc., 1911, 13, No. 4, 49) is used for ascertaining the freezing point, and the galvanometer is placed in a thermostat at 21° C. Advantages of the proposed method are that no treatment to eliminate proteins and other colloids is necessary, and that only a small volume of liquid, viz., about 2.5 c.c., is required. Readings of temperature may be obtained with an error of $\pm 0.003^\circ$, and 0.01° corresponds to 0.2% of sucrose.—J. P. O.

Lactose. J. Gillis. Rec. Trav. Chim. Pays-Bas, 1920, 39, 88—125.

PATENTS.

Sugar-making apparatus; Process of cleaning —. E. H. Man, New Orleans, La. U.S. Pat. 1,326,280, 30.12.19. Appl., 23.11.17.

SUGAR-MAKING apparatus is subjected to the action of aqueous sulphurous acid to soften the scale, which is afterwards removed.—J. H. J.

Vegetable carbons [used in sugar refining]; Process of regenerating —. A. Adams and S. S. Peck, Honolulu, Hawaii. U.S. Pat. 1,326,159, 30.12.19. Appl., 16.7.17.

To regenerate vegetable decolorising carbon used for purifying saccharine solutions, the material is fermented, then heated with sulphuric acid and/or a salt to remove gummy material and subsequently washed.—W. F. F.

Lactose or milk sugar; Manufacture of —. G. Martin, Manchester. Eng. Pats. 135,614 (Appls. 19,692, 28.11 and 21,833, 30.12.18) and 135,969, 13.12.18 (Appl. 20,836/18).

(A) WHEY is concentrated *in vacuo* to about one-

fifth of its original volume and heated at 70°–100° C. to precipitate as much as possible of the proteins, and metaphosphoric acid is added to precipitate the remainder. After separation from the precipitate the whey is concentrated as usual. (b) One or more of the following protein precipitants may be used: Tannic acid, mercurous nitrate, phosphotungstic acid, magnesium sulphate.

—J. H. L.

Starch; Method of preparing — [for textile fibres or fabrics]. *Starch preparing apparatus*. L. W. Goold, Birmingham. From American Laundry Machinery Co., Cincinnati, Ohio, U.S.A. Eng. Pats. (a) 135,591 and (b) 135,588, 27.11.18. (Appls. 19,530 and 19,520/18.)

(A) A MIXTURE of starch and water, after being cooked and agitated in a suitable vessel by injection of steam, is "creamed" by circulating between the vessel and an external apparatus, being, for example, withdrawn from the bottom of the vessel and re-introduced into the upper part in the form of fine jets. This method of circulation may also be employed for cooling and maintaining the liquid at the right temperature for use. If necessary uncooked starch may be introduced into the circulating liquid when this is sufficiently cooled. (B) Apparatus for carrying out the above process comprise a vessel, the bottom of which is provided with steam injectors, and an external circuit comprising a pipe connecting the bottom of the vessel through a pump with the lower ends of a bundle of vertical tubes, the upper ends of which are connected with a return pipe terminating in a spraying device inside the top of the vessel. The tubular bundle is enclosed in a casing through which cooling water or, if necessary, steam may be passed.—J. H. L.

Adhesives [from starch]; Process for the production of — V. G. Bloede, Catonsville, Md. U.S. Pat. 1,324,332, 9.12.19. Appl., 19.6.18.

A MODIFIED starch, or starch base, is produced by heating raw starch between 300° and 400° F. (149° and 204° C.) for $\frac{1}{2}$ –1 hour, according to the purpose for which the product is required, the temperature and duration of heating being so regulated that the product remains practically insoluble in cold water.—J. H. L.

Sugar-cane; Process for macerating crushed — C. McNeil, Glasgow. U.S. Pat. 1,323,090, 13.1.20. Appl., 22.4.18.

XVIII.—FERMENTATION INDUSTRIES.

Malt analysis; Application of formol titration to — H. Langkammer and H. Leberle. Z. ges. Brauw., 1919, 42, 236–239, 247–252, 259–262, 271–273, 280–282.

SÖRENSEN'S method of determining amino-acid and polypeptide nitrogen by formol titration (see this J., 1908, 135) was applied to 31 malts, and the authors conclude that it may prove useful in comparing the brewing characters of different malts. The "total formol nitrogen," determined on extracts made by digesting the ground malt with water for 4–5 hours at 46°–48° C. and filtering

(cp. Lüers and Adler, this J., 1915, 1158), ranged in most cases from 170 to 270 mgrms. per 100 grms. of malt dry substance; very similar results were obtained in operating on laboratory worts prepared in the ordinary way. The "original formol nitrogen" in the malt was determined on extracts made after destroying the malt enzymes by means of alcohol (*loc. cit.*), and ranged in most cases from 90 to 150 mgrms. per 100 grms. of malt dry substance. Abnormally small amounts of "formol nitrogen" are found with very short-grown or highly cured malts, whilst high results are obtained with malts prepared by the Kropff and similar systems. Dark malts usually contain less "formol nitrogen" than pale ones owing to destruction of amino-acids by Maillard's reaction (cp. this J., 1912, 144), but if dark malts are very highly modified they may still contain a relatively high proportion of "formol nitrogen." In general, in a series of malts, the content of "formol nitrogen" increases with other characters depending on enzymic activity, viz., rate of saccharification, acidity (determined by titration), and yield of extract. Worts rich or poor in "formol nitrogen" yield beers possessing corresponding characters. The amount present in a wort does not influence the reproductive or fermentative activity of the yeast, provided it is not too low; but a very high proportion in wort may impair the stability of the beer by hindering the production of the most favourable hydron concentration in the course of fermentation. (See also Adler; this J., 1914, 367.)

—J. H. L.

Yeast; Enzymic activities of — T. Bokorny. Allg. Brau-u. Hopfenzeit., 1918, 58, 1093. J. Inst. Brew., 1919, 25, 314–315. (See also this J., 1916, 900; 1917, 608; 1919, 958 A.)

THE zymase of yeast is rendered inactive by 0.2% formaldehyde solutions, and within two days by 0.1%, but not by 0.05% solutions; the invertase, however, survives two days' contact with 1% solutions. Mercuric chloride of 0.1% solution likewise prevents fermentation without inhibiting invertase action. By treatment with phenylhydrazine a yeast can be obtained which will ferment dextrose but not maltose. Alcohol of 10–20% concentration almost or entirely prevents fermentation without permanently destroying the zymase. Absolute alcohol destroys zymase activity within 10 minutes, but does not render the invertase inactive within 20 days.—J. H. L.

Yeast; Sensitiveness of living — towards hydra-gen and hydroxyl ions. H. von Euler and F. Emberg. Z. für Biologie, 1919, 69, 349. Woch. Brau., 1919, 36, 166.

THE authors investigated the influence of various hydron concentrations on the activities of the zymase, invertase, and maltase of a bottom-fermentation beer yeast. The zymase showed more or less activity over the range $p_H=9-2$. With increase in the hydron concentration from $p_H=9$ the zymase activity increased very rapidly to a maximum value which remained unchanged over a considerable range, but diminished gradually to zero as the acid limit, $p_H=2$, was approached. The invertase in the living yeast was affected by different hydron concentrations in the same way as invertase in the free state. The maltase was rendered quite inactive by a very faint alkalinity, $p_H=8$; as this reaction still permits the zymase and invertase to act, it should be possible, by maintaining such a reaction, to ferment only the sucrose in mixtures of this sugar with maltose. The authors also studied the effect of prolonged contact of the yeast with liquids of various hydron concentrations between $p_H=3.5$ and 7.2, and found that such treatment influenced

the enzymic activities (except that of invertase) and the synthetic processes associated with growth and reproduction.—J. H. L.

Yeast; Adaptability of — to different temperatures. H. Zikes. *Allg. Z. Bierbrau. u. Malzfabr.*, 1918, 46, 359. *J. Inst. Brew.*, 1919, 25, 315.

Six varieties of bottom-fermentation yeast, after cultivation for 25 days at 8° C., were found to grow more rapidly at temperatures below 20° C., and more slowly at higher temperatures, than the same varieties after cultivation for 25 days at 25° C. Further, the yeasts cultivated at 8° C. showed a better adaptability to high temperatures than those cultivated at 25° C. did to low temperatures.

—J. H. L.

Fermentation; Loss of alcohol during —. P. Harder. *Woch. Brau.*, 1919, 36, 277–279. *J. Inst. Brew.*, 1920, 26, 55–56.

THE relation between original wort gravity, residual extract, and alcohol-content of beers, as given by Balling's original formula (see Schönfeld, this J., 1910, 292; 1911, 762) is not strictly accurate. With bottom-fermentation beer the author found, after fermentation, an alcohol-content 0.03–0.04% lower than that required by the formula, irrespective of whether the fermentation was carried out in a covered vat or in an open vat exposed to a continuous strong current of air. The discrepancy can therefore not be attributed to loss of alcohol by evaporation; and an actual determination of the alcohol entrained by the fermentation gases, in the case of a covered vat, showed a loss of only about 0.001% of alcohol by evaporation. Both found much greater losses, e.g., 1.5%, in the fermentation of distillery mash, doubtless owing to the higher temperatures employed.—J. H. L.

Beers; Use of the Zeiss immersion refractometer for thin —, and criticism of the determination of original gravity in general. Dietsche and Grave. *Woch. Brau.*, 1919, 36, 237–240. *J. Inst. Brew.*, 1920, 26, 54–55.

THE alcohol and extract-contents of thin beers, of 1–3% Balling, may be calculated either from Barth's formulae (see Ackermann and Toggenburg, this J., 1906, 286) or from simpler formulae proposed by Lehmann and Gerum. According to the latter authors the extract-content, in grms. per 100 c.c., is given by the expression $0.9(R_0 + L)/7$, and the alcohol-content, in grms. per 100 c.c., by $2(R_0 - L)/7$, where R_0 is the scale reading of the Zeiss immersion refractometer less 15 (the reading for water), and L is the sp. gr. at 15° C. referred to water = 1000 and diminished by 1000.—J. H. L.

Acetyl methylcarbinol; Specific reaction of 2,3-buteneglycol and of — products of butyleneglycollic fermentation. Lemoigne. *Comptes rend.*, 1920, 170, 131–132.

PROOF of the formation of acetyl methylcarbinol during the bacterial decomposition of sugars serves to differentiate certain groups of similar organisms. The carbinol may readily be detected amongst the products of fermentation by the following process, the reaction not being given by any of the other products. A little of the culture (10, 50, or 100 c.c.) is mixed with 5 c.c. of ferric chloride solution and distilled. The carbinol is thus oxidised to diacetyl which passes over. To the first 3–4 c.c. of the distillate, 15–20 drops of ammonia, 5 drops of a 20% solution of hydroxylamine hydrochloride, and 5 drops of a 10% solution of nickel chloride are added. After a time (the length depending on the amount of diacetyl present) a red crystalline precipitate of nickel

dimethylglyoxime is obtained. By this method acetyl methylcarbinol may be characterised at a dilution of 1 in 1,000,000.—W. G.

Urease and the theory of the action of enzymes by radiation. H. P. Barendrecht. *Rec. Trav. Chim. Pays-Bas*, 1920, 39, 2–87.

AFTER a criticism of previous work, the author deduces a formula showing the velocity of action of urease at constant temperature and hydrogen ion-concentration, based on the theory of enzyme action by radiation. An experimental verification is given of the general law from the action of urease. The conditions governing the action of urease are examined, including the influence of foreign substances. The reversibility of the hydrolytic action with high p_H is shown. The influence of the concentration of the urease on the direct synthesis of urea is examined. A simple apparatus is described suitable for the measurement of the concentration of H ions or OH ions at constant temperature, with a hydrogen electrode or an oxygen electrode respectively.—W. G.

Alcohol and water; Determination of the composition of mixtures of — by electrical conductivity measurements. I. M. Kolthoff. *Rec. Trav. Chim. Pays-Bas*, 1920, 39, 126–131.

THE following procedure is recommended for the determination of the alcohol content of beer or wine. The excess of carbon dioxide is removed from the liquid by bubbling air through it, and the liquid is then distilled with magnesia. Fifty c.c. of the distillate is mixed with 10 c.c. of approx. N/2 oxalic acid solution and the mixture is made up to 100 c.c. with water. Similarly 10 c.c. of the N/2 oxalic acid solution is diluted to 100 c.c. with water. The specific conductivities x_1 and x_2 of these two latter solutions are then determined. Then $f_1 = 100x_1/x_2$ and f_1 can be converted to f_{10} by means of a temperature coefficient. A table is given showing the relationship between f_{10} and the alcohol content of the distillate.—W. G.

PATENTS.

Beer; Process for preserving non-alcoholic — and other fermentable liquids. H. C. M. Franks, New York. Eng. Pat. 136,448, 25.4.19. (Appl. 10,315/19.)

THE liquid, maintained at about 35° C. in a pressure tank, is subjected to carbon dioxide under a pressure of about 60 lb. per sq. in., and agitated meanwhile, after which the pressure is reduced below 1 atm. These operations are repeated and finally the liquid is left for a time under a 60 lb. pressure of carbon dioxide. It may then be transferred to sterile receptacles and sealed. The process is stated to prevent or arrest all fermentative or bacterial action.—J. H. L.

Saccharification of wood and other cellulosic substances by treatment with sulphuric acid, and recovery of the latter. Zellstoff-fabrik Waldhof, and H. Clenm, Mannheim-Waldhof. Ger. Pat. 305,180, 12.5.17.

THE cellulosic material is made into a paste with sulphuric acid, which is then partly neutralised by ammonia, leaving only enough acid for the sugar formation. After saccharification the acid is completely neutralised and the liquor boiled down and cooled for separation of the ammonium sulphate. The ammonium sulphate left in the mother-liquor is of value as yeast food in the subsequent fermentation process. The spent wash from the fermentation process may be evaporated to obtain a fertiliser.—B. V. S.

Sugar and dextrin from wood and other cellulosic material; Process for obtaining — Zellstoff-fabrik Waldhof, and V. Hottenroth, Mannheim-Waldhof. Ger. Pats., (A) 309,150, 19.4.17; (B) 310,149, 7.9.17; (C) 310,150, 9.2.18.

(A) THE wood or other material is mixed into a paste with less than 3 parts of sulphuric acid not more concentrated than 85%, high pressures being avoided. This is allowed to stand for some time, then mixed with water, and boiled. The actual quantity of sulphuric acid depends on the quality of the material to be treated, but is generally from $\frac{1}{2}$ to 1 part of acid to 1 part of the material; the cellulose should not be dissolved. For example, 1 kilo. of sawdust requires 1 litre of 75% acid; after some hours' standing 14 litres of water is added. Lignin remains undissolved and the solution contains dextrin, which is converted into sugar by boiling. (B) The excess of sulphuric acid above that required for conversion of the dextrin into sugar, or the whole of the acid if the dextrin is required as such, is removed by dialysis. (C) By using a copper ferrocyanide dialysing membrane the acid remaining with the sugar, after conversion of the dextrin by boiling the solution, is removed, since sugar does not pass through such a membrane. —B. V. S.

Products from reeds. Ger. Pat. 304,285. See V.

XIXA.—FOODS.

Milk; Decomposition of hydrogen peroxide by micro-organisms extracted from pasteurised — M. Fouassier. Comptes rend., 1920, 170, 145—147.

IN addition to the lactic ferments certain organisms such as *B. subtilis*, *Tyrophix tenuis*, *Oidium lactis*, and a yeast have been isolated from pasteurised milk. All of these, except the lactic ferments, decompose hydrogen peroxide at a concentration of 1% in a lactose-peptone medium, but only the two first named can resist the action of hydrogen peroxide at a concentration of 4%. This decomposition of the hydrogen peroxide continues to be manifested after filtration of the culture medium through a porous candle, but is stopped if the medium is heated to 80° C.—W. G.

Milk; Detection of hydrogen peroxide in pasteurised — by means of guaiacum tincture. M. Fouassier. Ann. Chim. Analyt., 1920, 2, 9—11.

THE peroxydase necessary for the detection of hydrogen peroxide in pasteurised milk by the guaiacum test may be obtained from potatoes. A peeled potato is macerated with water, and the milk to be tested is treated with about 10% of its volume of the maceration.—W. P. S.

Gluten; Determination of dry — [in flour]. J. Bouyer. Bull. Soc. Pharm. Bordeaux, 1919, No. 2. Ann. Chim. Analyt., 1920, 2, 20—21.

THE gluten obtained in the usual way is pressed by the fingers into a cake, which is placed on a cover glass and dried at 105° C. for 30—45 mins.; the cake is then turned over, dried for a further 30—45 mins., and cut into strips by means of a pair of scissors. The strips are dried for 30 mins., then cut into small pieces and the drying continued to constant weight. This final drying requires about 6 hours.—W. P. S.

Sugar; Quantitative estimation of small quantities of — in the presence of the higher and lower products of protein degradation. E. Last. Biochem.-Zeits., 1919, 93, 66—82.

THE higher products of protein degradation like

albumoses and peptones, the presence of which interferes with the estimation of sugar, can be removed by means of mercuric chloride in neutral solution. The sugar can then be estimated by Bertrand's methods (this J., 1907, 60). In the presence of acids the precipitation of these products is incomplete. An excess of mercuric chloride must also be avoided in order to ensure good results; 2 grms. of mercuric chloride per gm. of peptone was found to be a suitable quantity. The presence of monoamino acids does not affect the accuracy of the sugar estimation by Bertrand's method, but ereptone does influence the results. This is due to the special atomic grouping in ereptone, which on boiling with alkali liberates ammonia, and this dissolves some of the cuprous oxide. Ereptone can also be removed from sugar solutions by precipitation with mercuric chloride in alkaline solution. The removal of both the higher and lower products of protein degradation with mercuric nitrate according to the Patein-Dufau method conduces to accurate results. —S. S. Z.

Plant juices; Electrometric titration of — A. R. C. Haas. Soil Sci., 1917, 7, 487—491.

A SIMPLIFIED and inexpensive type of the gas-chain apparatus, essentially of Hildebrand's form (Univ. Cal. Pub. Physiol., 1919, 5, 44), is described, and by means of it the p_H values of the juice of soya bean tops and rhubarb stalk were determined. The curves show the presence of greater quantities of buffer substances in rhubarb juice than in the juice of soya bean tops, the actual acidity of the rhubarb juice being much greater than that of the juice of soya bean tops.—W. G.

Sucrose; Inversion of — during the preservation of oranges. G. André. Comptes rend., 1920, 170, 126—128.

THE amount of sucrose inverted during four months when half of an orange is kept under aseptic conditions at the ordinary temperature bears no relationship to the acidity of the orange expressed as citric acid.—W. G.

PATENTS.

Casein and vegetable albumen, including gluten; Process for the manufacture of a colloidal solution, neutral to the taste, from — M. Monhaupt, Altona-Ottensen, Germany, Assignor to Naaml. Vennoots. A. Jurgens Vereenigde Fabrieken, Oss, Netherlands. U.S. Pat. 1,326,210, 30.12.19. Appl., 25.3.18.

CASEIN is treated with excess of magnesia, the excess not exceeding 1.5% by weight of the casein. —J. H. J.

Fat for shortening purposes; Comminuted edible — and method of making the same. H. A. Kohman, T. M. Godfrey, and L. H. Asche, Pittsburgh, Pa., Assignors to Ward Baking Co., New York, N.Y. U.S. Pat. 1,326,276, 30.12.19. Appl., 9.3.16.

FAT at a temperature above its melting point is sprayed into a cooling chamber, the spraying being regulated to cause the deposition of the fat in a sufficiently fine state of subdivision to permit of homogeneous incorporation with the material to be shortened.—J. H. J.

Cattle-food; Preparation of a — [from tannery offal]. E. Meyer und Co., Guben. Ger. Pat. 314,957, 9.11.15.

TANNERY offal is treated by known processes, e.g., mincing, cleaning, and cooking or treating with preservatives.—A. R. P.

Drying vegetables and the like; Apparatus for —. D. Brons, Assignor to N. V. Machinefabriek Brons, Zuidbroek, Netherlands. U.S. Pat. 1,326,909, 6.1.20. Appl., 28.5.19.

SEE Eng. Pat. 128,199 of 1919; this J., 1919, 875A.

Products from reeds. Ger. Pat. 304,285. See V.

Fibrous material etc. from pea-pods. Ger. Pat. 307,626. See V.

XIXB.—WATER PURIFICATION; SANITATION.

Industrial poisoning; Recent experiences on —. Koelsch. Z. angew. Chem., 1920, 33, 1—5.

A DISCUSSION of the general conditions resulting in poisoning is followed by an account of the symptoms and diagnosis of poisoning by alcohol, lead, mercury with its fulminate and chloride, arsenic and hydrogen arsenide, oxides of manganese, mineral acids, nitrous fumes, carbon tetrachloride, tetrachloroethane, trichloroethylene, amyl acetate, hydrocyanic acid, cyanamide, benzene and its nitro-derivatives, trinitrotoluene, tetranitromethane, trinitroanisole, and amino-derivatives of benzene.—J. K.

Humus; Chemical properties of — and their utilisation for the protection of combatants against asphyxiating gases. Griffon du Bellay and Houdard. Comptes rend., 1920, 170, 236—238.

SOIL absorbs gases such as benzyl bromide, chlorine, or carbonyl chloride, the retentive power varying with the type of soil, being almost nil for a very sandy soil and increasing with the amount of plant debris present. The phenomenon is chemical and exothermic. The fixation of the gas is facilitated by moisture. Humus dried at 100° C. has at the most only two-thirds of its original power of absorption. The results indicate that a layer of soil 60 cm. thick, well supplied with organic matter, could protect combatants for several hours against the war gases in use in February, 1916, provided the amount of gas passing through the soil did not exceed 1 litre per sq. decm.—W. G.

PATENTS.

Antiseptic material; Process for production of —. Verein für Chemische Industrie in Mainz, Frankfurt. Ger. Pat. 315,017, 21.4.16.

AN antiseptic material, particularly adapted to the formation of a stable, impermeable, sterile covering for various parts of the human body, such as the hand or arm, is obtained from such formaldehyde-phenol condensation products as are pliable and nearly liquid at body temperature. A solution of these in a suitable solvent such as alcohol is mixed with a solution of cellulose esters, to which may be added other antiseptics, colouring matters, or substances to increase the pliability.—B. V. S.

Iron oxide slimes. Ger. Pat. 305,083. See VII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Toxicity in sera and physical properties of colloidal gels. W. Kopaczewski and Z. Gruzewska. Comptes rend., 1920, 170, 133—135.

ANIMAL serum in contact with colloidal gels, such as gelose and pectin, acquires astonishing toxic properties, whereas other gels, of an apparently

identical consistency and structure, do not provoke this toxicity. It is now shown that the development of toxicity is dependent on the electrophoretic character of the gels. In the case of three silica gels prepared in different ways, electro-negative silica gel provoked marked toxicity in guinea-pig serum, whereas an electropositive gel or an amphoteric gel was without effect. From a study of the effect of starch gels, the importance of the micellar structure of the gels in the production of toxicity in sera by contact is shown.

—W. G.

Surface active substances; Adsorption of the so-called — by various adsorbents. L. Michaelis and P. Rona. Kolloid-Zeits., 1919, 25, 225—229.

CHARCOAL is by far the best adsorbent for non-electrolytes such as acetone, tributyrin, and heptyl alcohol. Of other adsorbents examined only in the case of talc was a measurable adsorption observed.

—J. F. S.

Aromatic diamines; Physiological experiments with —. R. Meissner. Biochem.-Zeits., 1919, 93, 149—163.

THE toxicity of some aromatic diamines, triamino-benzene, triaminotoluene, and triaminophenol has been tested on rabbits, cats, and frogs. (See J. Chem. Soc., Mar., 1920.)—S. S. Z.

Vanillin; Oxidation of — to vanillic acid by certain soil bacteria. W. J. Robbins and E. C. Lathrop. Soil Sci., 1919, 7, 475—485.

IN mineral nutrient solution containing vanillin as the only source of carbon, certain bacteria present in some Alabama soils (see Robbins, Alabama Agr. Exp. Stat., 1917, Bull., 195) oxidise the vanillin to vanillic acid, which at first accumulates in the culture solution but later is destroyed. Estes' acid mercuric nitrate reagent (this J., 1917, 352) gives satisfactory results for the estimation of vanillin in the presence of vanillic acid, but the phenol reagent of Folin and Denis (this J., 1912, 949) is unsatisfactory as vanillic acid, like vanillin, gives a blue colour with the reagent, the colour produced by the acid being much deeper than that produced by an equivalent amount of the aldehyde.

—W. G.

Gluconic acid; Preparation of — [from starch glucose]. A. Herzfeld and G. Lenart. Z. Ver. deut. Zuckerind., 1919, 122—128.

DURING the war a technical method for the preparation of gluconic acid to serve as a substitute for tartaric and citric acids was devised in Germany. Dextrose (starch glucose) was oxidised with chlorine or bromine, the excess of halogen was distilled off, and the liquid neutralised with sodium carbonate. Calcium carbonate was added, the temperature being raised during this operation to 90° C. to transform any lactone present, the liquid cooled, and the calcium gluconate obtained purified by recrystallisation. An almost quantitative yield is said to have been obtained. (See also J. Chem. Soc., Mar., 1920.)—J. P. O.

Urea; Behaviour of — towards hydrogen peroxide and a simple process for its purification and decolorisation. H. Kuntz-Krause. Kolloid-Zeits., 1919, 25, 240—241.

UREA is not affected by boiling with hydrogen peroxide but the colour (blue or green) which is often found in commercial urea and which consists of colloidal Prussian blue is decomposed, ferric hydroxide being precipitated.—J. F. S.

Chlorinated methyl formates; Industrial — and their analyses. M. Delépine. Bull. Soc. Chim., 1920, 27, 39—45.

WHEN methyl formate is chlorinated in sunlight

a number of chloromethyl formates and chloromethyl chloroformates may result. These esters when decomposed by dilute sodium hydroxide behave as follows:—

From the quantities of formaldehyde, formic acid, and carbon monoxide formed, together with a knowledge of the chlorine content of the original material, it is possible to form an idea of the constituents of the chlorinated material: 0.4 c.c. of the mixed chlorinated esters is added to 50 c.c. of *N*/1 sodium hydroxide solution and shaken. After half an hour the mixture is diluted to 125 c.c. Of this solution 25 c.c. is used for the estimation of formaldehyde by Romijn's method with *N*/10 iodine solution (this *J.*, 1897, 366), and another 25 c.c. is used for the estimation of formic acid by oxidation with potassium permanganate by St. Gilles' method (*Ann. Chim. Phys.*, 1859, 55, 374). For the estimation of carbon monoxide 0.3–0.5 grm. of the chlorinated material is introduced into a ureometer, treated with 10 c.c. of 4*N* sodium hydroxide, and the volume of carbon monoxide is read off as soon as the decomposition is complete.

—W. G.

Chlorinated methyl carbonates; Properties of the —. A. Kling, D. Florantin, and E. Jacob. *Comptes rend.*, 1920, 170, 231–236.

The physical properties of the nine possible chlorinated methyl carbonates are given as below:—

Formula	m.pt.	b.pt. at 760 mm.	b.pt. at 50 mm.	sp. gr. at 15°C.
$\text{CH}_3\text{Cl.O.CO}_2\text{CH}_3$	—	139–140°C.	67°	1.303
$\text{CO (O.CH}_2\text{Cl)}_2$	—	176°C.	99°	1.480
$\text{CHCl}_2\text{O.CO}_2\text{CH}_3$	—	147°C.	72°	1.421
$\text{CHCl}_2\text{O.CO}_2\text{CH}_2\text{Cl}$	—	178°C.	102°	1.562
$\text{CCl}_3\text{O.CO}_2\text{CH}_3$	–70°C (viscous)	165°C.	86°	1.535
$\text{CO (O.CHCl}_2)_2$	–40°C	182–183°C.	105–106°	1.618
$\text{CCl}_3\text{O.CO}_2\text{CH}_2\text{Cl}$	–70°C	150°C.	110°	1.631
$\text{CCl}_3\text{O.CO}_2\text{CHCl}_2$	–30°C (viscous)	196°C. (decomp.)	115°	1.686
$\text{CO (O.CCl}_3)_2$	78°C	203°C. (decomp.)	124°	—

All of these substances are lachrymators, those compounds containing the group O.CCl_3 being particularly toxic.—W. G.

Acetone; Micro-method for the estimation of —. M. Richter-Quittner. *Biochem.-Zeits.*, 1919, 93, 163–172.

A MICRO-METHOD in which 1–2 c.c. of urine and 15–3 c.c. of alkali need only be used. The urine is distilled once with steam in the presence of acetic acid and a second time with dilute sulphuric acid. Blood or plasma need only be distilled once, and instead of the steam, air is passed through the heated flask. The titration of the distilled acetone is carried out with *N*/100 iodine and *N*/100 sodium thiosulphate. 0.1 mgrm. of acetone in 100 c.c. can be estimated with accuracy by this method. The quantity of urine and blood used must not contain less than 0.04 mgrm. of acetone.—S. S. Z.

Acetaldehyde, metalddehyde, and ethyl alcohol; Mode of pyrogenic decomposition, at high temperatures, of —. E. Peytral. *Bull. Soc. Chim.*, 1920, 27, 34–39.

WHEN acetaldehyde is submitted to a high temperature for a short time the main decomposition is expressed by $\text{CH}_3\text{CHO} = \text{CH}_4 + \text{CO}$, a second simultaneous change, which proceeds to a far less extent, being $2\text{CH}_3\text{CHO} = 2\text{CO} + \text{C}_2\text{H}_4 + 2\text{H}_2$. If the time of heating is prolonged secondary changes occur, with the formation of acetylene and benzene. Under similar conditions metalddehyde is first depolymerised to acetaldehyde, which then undergoes the

changes given above. In the case of ethyl alcohol there are two main changes, the first of which predominates:—

The acetaldehyde formed undergoes pyrogenic decomposition as described.—W. G.

Unsaturated substances; Action of iodine on —. *Pseudo-iodine value of essential oils.* R. Huerre. *J. Pharm. Chim.*, 1919, 20, 216–224, 250–257, 273–281.

IN the reaction between terpenes or terpenic essential oils and an alcoholic solution of iodine the absorption of iodine is independent of the concentration of the iodine solution, or of variations of temperature from 15° to 45° C., and is a function of the excess of iodine present. This absorption is not due, for the most part at all events, to addition of the iodine, and the name pseudo-iodine value is suggested for it. This value may therefore be defined as the maximum quantity of iodine absorbed in 2 hours by 100 grms. of hydrocarbon or essential oil from an alcoholic solution of iodine containing the optimum excess of iodine. In the case of pure cedrene the pseudo-iodine value (39.60) was much lower than that of pinene (238). The maximum absorption of iodine was obtained when a little more than 3 grms. of iodine was made to react with 0.25 grm. of cedrene. In the case of limonene the maximum absorption of iodine (309) was obtained when the amount of iodine present was 16 times that of the limonene.—C. A. M.

Terpene; Occurrence of the terpene — in the oil of *Eucalyptus megacarpa*. H. G. Smith. *J. Proc. Roy. Soc. N.S.W.*, 1918, 52, 529–533.

THE oil of *Eucalyptus megacarpa* contains pinene, limonene, and dipentene, about 30% of cineol, and possibly as much as 10% of terpinene. The latter was detected in the fraction boiling at 170°–190° C. by the formation of its nitrosite, m. pt. 155° C., and by its rapid oxidation in the cold with Beckmann's chromic acid mixture, as evidenced by the increased optical rotation of the residual oil (consisting mainly of limonene) after the removal of the inactive terpinene.—G. F. M.

Regenerating chromic acid. McKee and Leo. See VII.

Acetyl methylcarbinol. Lemoigne. See XVIII.

PATENTS.

Acetic acid; Process of recovering — and manufacturing acetates. H. W. Matheson, Shawinigan Falls, Canada. Eng. Pat. 137,388, 23.1.19. (Appl. 1730/19.)

THE hot vaporous mixtures emerging from the conversion tubes in the manufacture of acetone from acetic acid are passed into an alkaline solution at 85°–100° C., which is maintained in motion to promote the absorption of the acetic acid; concentration of the resulting solution occurs concurrently, and the resulting sodium acetate is finally separated from the water by crystallisation.—D. F. T.

Fatty acids; Process for the preparation of esters of —. Farbw. verm. Meister, Lucius, and Brüning, Höchst. Ger. Pat. 315,021, 19.9.15.

ACETYLENE is allowed to react, preferably at a high temperature, on an equimolecular mixture of a fatty acid and alcohol in the presence of the mercury salt of a mineral acid. For example, precipitated mercuric oxide is dissolved in acetic acid at 30°–40° C., and the solution treated, drop by drop, with strong sulphuric acid so as to precipitate mercuric sulphate in a finely divided state.

Ethyl alcohol is added to the mixture, which is heated to 70° C. in a shaking apparatus fitted with a reflux condenser, while a current of acetylene is passed through it. The acetaldehyde produced is separated from the ethyl acetate by fractional distillation. Formic acid and ethyl alcohol yield ethyl formate, and propionic acid and methyl ether give methyl propionate.—A. R. P.

Tobacco; Process of curing —. E. G. Reinhardt, Washington, D.C. U.S. Pat. 1,327,692, 13.1.20. Appl., 8.5.19.

The leaf, whether harvested separately or upon the stalk, is submitted to the action of air at about 105° F. (41° C.) and of about 60% relative humidity so as to reduce the moisture content and form a green overcast due to a film of dead chlorophyll cells in the leaf surface; the air is then changed to a temperature of 90° F. (32° C.) and a relative humidity of 95% for about 48 hours to bring the colour of the leaf to a mottled yellow, and the characteristic appearance and quality of well-cured tobacco are then developed by treatment with air at about 105° F. and of 72% relative humidity, 48—72 hours being generally sufficient for this final stage.—D. F. T.

Cacodyl and cacodyl oxide (Cadet's fuming liquid); Preparation of non-inflammable —. E. Merck, Darmstadt. Ger. Pat. 299,040, 16.3.15.

The inflammability of cacodyl and cacodyl oxide is greatly reduced, and even entirely overcome, by the addition of suitable amounts of sulphur.—W. J. W.

Odorous substances; Fixation of — in solid or liquid media. O. Bracmer, Hamburg. Ger. Pat. 314,829, 19.3.18.

TANNIC acid or gallic acid or one of their salts is added to the substance along with the characteristic essential oil, and in some cases with the further addition of sugar. The process is applicable to the manufacture of perfumes, soaps, scent-sachets, and, particularly, of artificial seasonings. For instance, in the preparation of artificial cinnamon, an intimate mixture of cinnamon oil, tannic acid, and sugar is incorporated with potato or turnip meal.—B. V. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Hypersensitising [photographic] panchromatic plates. S. M. Burka, J. Franklin Inst., 1920, 189, 25—46.

If panchromatic plates are treated with ammonia

before exposure, their speed is very considerably increased, but their keeping quality is considerably reduced. A similar treatment has an almost negligible effect on most ordinary or orthochromatic plates, and the effect is apparently due to interaction between the dyes used in the panchromatic plates and the ammonia. The speeding effect was greatest if a plain aqueous ammonia solution was used, but plates so treated would keep for only 2 or 3 days; the bath recommended for use contains 25% of ethyl alcohol and 3% of 20% aqueous ammonia solution. The plates are bathed for 4 minutes and dried rapidly. The increase of speed to white light is in most cases about 100%, and more to red light, being in some cases 400%. The sensitiveness in the red is also extended about 100 Angström units. The spectral sensitiveness curve is also somewhat smoother after treatment. A number of tables, diagrams, and illustrations are given, showing the effect of the treatment on various brands of panchromatic plate.—B. V. S.

[Photographic] sensitising with bichromate. R. Namias. II Progressio Fotog., 1915, 208. Bull. Soc. Franç. Phot., 1919, 6, 331—332.

CARBON-TISSUE paper sensitised with bichromate keeps for only a few days. If the normal salt or the normal salt with a small addition of alkali be used in place of the bichromate, the paper keeps almost indefinitely, but is too slightly sensitive for use. The combination of good keeping quality and high sensitiveness may be obtained by coating the paper with a mixture containing slightly alkaline chromate, and then treating it, just before use, for about half an hour in a closed box at ordinary temperature with the vapour of a volatile acid, such as acetic acid.—B. V. S.

PATENTS.

Wedge colour-filter for distant photography. O. Will, Munich. Ger. Pat. 309,167, 28.8.17.

A COMPOSITE colour-filter contains two or more wedge filters, cemented between glass; the different wedges may be of different colours and their slopes may be in the same or in opposite directions.

—B. V. S.

Selenium cells. Ger. Pat. 301,261. See XI.

XXII.—EXPLOSIVES; MATCHES.

Specific heat of mixtures of sulphuric and nitric acids. Pascal and Garnier. See VII.

PATENTS.

Explosives; Process for manufacture of —. Zentralstelle f. Wissensch.-tech. Untersuch., G.m.b.H., Neubabelsberg. Ger. Pat. 299,028, 15.6.16.

AN explosive consists of nitro-hexamethylenetetramine, $C_6H_{12}N_4O_6$ (Ger. Pat. 101,280), which may be mixed with other ingredients. The explosive is stable, sensitive to shock, and gives a good expansion in the Trauzl lead block.—W. J. W.

Nitrocellulose powder; Process for increasing the density or diminishing the porosity of — in the form of cords or threads. I. M. Voith, Heidenheim. Ger. Pat. 300,737, 21.4.17.

THE amount of collodion cotton added to the explosive for gelatinising purposes is raised from 20—25% to 27—30% in order to increase the density. To prevent the newly pressed powder from becoming porous when treated with water, the collodion cotton may be increased to 45%.

—W. J. W.

Explosives; Process for "drying" [removing solvent from] freshly manufactured —. I. M. Voith, Heidenheim. Ger. Pat. 302,560, 30.6.16.

THE removal of solvent from tubular or cord-shaped explosives may be effected by treatment with water or aqueous solutions of alcohol, acetone, salts, etc. The process is free from danger, and is said to be more rapid than drying by hot air or in a vacuum.—W. J. W.

Cellulose products; Process for displacement of liquids from — by other liquids. Elektro-Osmose Akt. Ges. (Graf Schwerin Ges.), Berlin. Ger. Pat. 305,019, 25.10.17.

THE displacing liquid is forced under pressure through a thin layer of the material, swelling of the material being prevented. The process may be carried out at raised temperatures. The density of the material may be increased by a preliminary pressing. The method may be utilised for the displacement of water from nitrocellulose by means of alcohol.—W. J. W.

Perchlorate explosives; Increasing the sensitiveness of — by addition of potassium permanganate as catalyst. C. Bunge, Bradegrube. Ger. Pat. 303,289, 8.4.17.

POTASSIUM perchlorate and potassium permanganate are crystallised together and the mixed crystals of suitable size are incorporated with other ingredients. By this means the full catalytic effect of the permanganate is made available, and its decomposition by other ingredients, such as oxalates, is avoided.—W. J. W.

Nitro-urea explosive. Badische Anilin- u. Soda-Fabrik, Ludwigshafen. Ger. Pat. 303,929, 17.7.15.

NITRO-UREA or its compounds or derivatives are mixed with inorganic oxygen-evolving compounds, or with other explosives. A suitable composition contains nitro-urea, 83%; potassium nitrate, 17%. If 10% of nitro-urea is added to 90% of ammonium nitrate it increases the "brisanee" of the latter. As nitro-urea is not very sensitive, a strong detonator is required.—W. J. W.

Ammonium perchlorate explosive. O. B. Carlson, Mansbo, Assignor to Aktiebolaget Carlit, Stockholm, Sweden. U.S. Pat. 1,327,985, 13.1.20. Appl., 25.9.17.

SEE Eng. Pat. 112,417 of 1917; this J., 1918, 637 A.

XXIII.—ANALYSIS.

Melting point methods at high temperatures. II. L. I. Dana and P. D. Foote. Chem and Met. Eng., 1920, 22, 63—70. (See also this J., 1920, 175 A.)

THE melting point of silicates is determined preferably in a tall form of metal crucible, using an unprotected thermo-couple, and leakage of current from the couple to the molten salt and from the furnace heating current to the couple must be considered in precision work. Platinum resistance thermometers give greater accuracy than thermo-couples below 800° C., but above this temperature the calibration is subject to changes on account of volatilisation of platinum, and of strains introduced by the warping of the mica frame. Above 1400° C. the melting point of metals is observed through a hole in the cover of a crucible containing the metal, by means of an optical pyrometer. The crucible should be set in an outer tube of non-porous material which is inserted into the heating chamber. A vacuum furnace, such as the Arseni graphite resistance furnace, is necessary if the metal is subject to oxidation. A modification of the

wire method may be used for metals melting above the range of platinum. The material in the form of wire or ribbon is heated electrically until it fuses and the highest intensity is measured by an optical pyrometer. This method involves a knowledge of the emissivity of the particular material. Micropyrometric observations are subject to error because of the unequal heating of the platinum strip and the sample resting on it by the traversing current. In general the specimen should be protected from reducing action in the furnace by means of a suitable surrounding tube. Sillimanite porcelain may be used for this purpose up to 1800° C., but no protection tubes have been found satisfactory for higher temperatures.—C. A. K.

Qualitative analysis in the presence of phosphoric acid; Procedure for —. H. Remy. Z. anal. Chem., 1919, 58, 385—392.

IN the scheme of analysis described, phosphoric acid is used as a group reagent. The solution, containing any of the common metals, alkaline-earth metals, and alkali metals, and phosphoric acid, is treated with hydrogen sulphide and the sulphides are filtered off; the filtrate is boiled, filtered, and oxidised with nitric acid. Ammonium carbonate is added until the solution is nearly neutral, the mixture is poured into an equal volume of ammonia and an excess of ammonium phosphate is added. Aluminium, chromium, iron, calcium, strontium, and barium are precipitated as phosphates and manganese and magnesium as ammonium-phosphates; zinc, nickel, cobalt, and alkali metals remain in solution (sol. 1). The precipitate is separated, dissolved in a small quantity of hot dilute hydrochloric acid and potassium sulphate solution is added; barium, strontium, and the greater part of the calcium are precipitated and may be separated from each other and identified in the usual way. The filtrate from the alkaline-earth sulphate precipitate is heated to boiling with the addition of solid sodium acetate and ammonium chloride; iron, chromium, aluminium, and manganese are precipitated (ppt. A). The filtrate from this precipitate is treated with ammonium oxalate to precipitate the remaining quantity of calcium, and is subsequently rendered ammoniacal to precipitate magnesium. The precipitate (A) is dissolved in hydrochloric acid, the solution heated and sodium carbonate is added as long as the precipitate formed redissolves; the solution is then poured, while warm, into a mixture of 20% sodium hydroxide solution and hydrogen peroxide. Ferric hydroxide and hydrated manganese dioxide are precipitated whilst chromium and aluminium remain in solution as chromate and aluminate, respectively. The iron is identified by the ferrocyanide reaction and manganese by conversion into permanganate. Aluminium is precipitated as hydroxide by boiling the aluminate solution with the addition of ammonium chloride, and chromium is identified by the usual tests. The solution (I) containing the zinc etc. is heated and treated with ammonium sulphide; on adding hydrochloric acid to this precipitate, the zinc sulphide dissolves leaving the nickel and cobalt sulphides insoluble. The two latter metals may be identified in the usual way. The filtrate from the total sulphide precipitate contains the potassium and sodium together with phosphoric acid, but the latter does not interfere with the perchloric acid test for potassium or with the pyroantimonate test for sodium.—W. P. S.

Calcium; Modified McCrudden gravimetric method for [the determination of] —. J. O. Halverson and J. A. Schulz. J. Ind. Eng. Chem., 1920, 12, 77—78. (See also this J., 1911, 1282.)

IN the modification proposed the calcium oxalate precipitate is collected on a specially prepared asbestos filter and then titrated with perman-

ganate. High-grade ignited asbestos is heated at 60° – 70° C. for 1 hour with dilute sulphuric acid (1:5), and then washed with water containing a trace of permanganate until free from acid. By shaking the washed asbestos with water it may be separated into three grades of fineness—fine, medium, and coarse. A layer of the coarse is placed in a Gooch crucible, and on this are placed layers of the medium and fine grades respectively. After the precipitate has been washed the filter and precipitate are transferred to a flask containing hot water, sulphuric acid (1:5) is added, and the oxalate titrated at 65° C. with permanganate.—W. P. S.

Arsenic; Process for the estimation of — with notes on the chemistry of the Marsh-Berzelius process. B. S. Evans. Analyst, 1920, 45, 8–17.

THE arsenic is evolved as hydrogen arsenide, which is passed over ignited copper and the arsenic retained by the copper is weighed. The apparatus used is essentially the same as in the Marsh-Berzelius method, but the tube attached to the drying tube has a drawn-out portion only about 2 in. long, the last inch of which is turned up. If this tube is made of silica it can be used repeatedly. A roll of thin sheet copper about 4 in. by 1 in., previously heated to redness and cooled, is introduced into the silica tube, which has a small fragment of ignited asbestos wool at the constriction, and the tube is supported horizontally over a Bunsen flame, whilst the portion containing the copper is covered by a small sheet iron muffle about $1\frac{1}{2}$ in. long, and a small asbestos sheet is used to protect the rubber connexion. After hydrogen has been passed through the tube for 2 or 3 mins. the burner is removed, the tube allowed to cool, the hydrogen replaced by air by means of a filter pump, and the tube weighed. It is then again attached to the hydrogen flask, again heated, and the hydrogen jet relighted. When the tube is red hot the solution containing the arsenic under examination is introduced into the flask, and the evolution of gas continued for 45 mins., the height of the hydrogen flame being maintained at about $\frac{1}{2}$ in. Finally the tube is cooled, and after removal of the hydrogen is weighed as before. The increase in weight divided by 0.986 gives the amount of arsenic. This correction factor was based upon results obtained with different amounts of pure arsenious oxide. Experiments indicated that the loss of arsenic was not due to its leaving the apparatus with the hydrogen. When pure zinc was used a scum of elementary arsenic formed on the surface of the acid and remained practically unchanged at the end of the test. This represented a considerable loss of arsenic, but by coating the zinc with cadmium, as suggested by Chapman, the floating arsenic is removed. To prevent separation of elementary arsenic it is advisable to keep the amount of arsenic added well below 0.5 gm. The addition of copper sulphate to the liquid in the flask prevents the formation of arsine by the formation of copper arsenide and by causing a large amount of elementary arsenic to separate. In the case of iron the amount of arsenic retained is approximately proportional to the amount of iron present. The arsenide residues invariably contained lead, derived from the cadmium, and apparently brought into combination with the arsenic through the influence of the iron. Sodium sulphate, disodium hydrogen phosphate, and zinc sulphate have no retaining effect. This method was used to test the amount of arsenic left in solution in the filtrate and washings in the magnesium arsenate method. It was found that the second filtrate containing no magnesium mixture dissolved about four times as much arsenic as the first, although its volume was not much greater. The amount of arsenic remaining in solution is by no means negligible, and it is

necessary to see that the volumes of both filtrates and washings are kept constant when solution factors are used to correct the results. (See also J. Chem. Soc., 1920, ii., 125.)—C. A. M.

Arsenic; Estimation of small quantities of —. W. van Rijn. Pharm. Weekblad, 1919, 56, 1072–1083.

SMALL quantities of arsenic, as little as 1 mgrm. As per litre, may be accurately estimated by the following methods:—Treatment with potassium chlorate and hydrochloric acid (Fresenius and Babo); absorption by ferric hydroxide (Paucke. Beitr. z. Nachw. v. Arsen, Inaug. Diss., Leipzig, 1908); acidification with sulphuric acid, addition of solution of bromine in potassium bromide, then ammonia and magnesia mixture; or treatment with ammonia and magnesia mixture and addition of sodium phosphate (Berntrop). The arsenic mirror is obtained by the use of Bloemendaal's apparatus and the final estimation by titration (Berntrop, Chem. Weekblad, 1906, 315). Comparison with a standard mirror is not sufficiently accurate. Wallpapers, paint and blind materials may be tested by the same methods.—W. J. W.

Fat extraction apparatus. J. M. Pickel. J. Ind. Eng. Chem., 1919, 11, 1053–1055.

THE extraction vessel consists of a small glass cylinder, A, in place of the usual flask; a crucible, B, containing the substance to be extracted is supported in the cylinder, indentations being provided in the side of the cylinder for this purpose. A cup, C, inside which at one side is a funnel (the bent stem of this funnel passes through the bottom of the cup), fits over the top of the crucible, and a condenser, A, is attached to the top of the cylinder. When the ether in the latter boils the vapours are condensed and fall from the condenser through the funnel into the crucible containing the substance. At the end of the extraction the condenser is rotated partially, so that the condensed ether falls into the cup and does not return to the cylinder.—W. P. S.

Uranium; Determination of — and its separation from other rare elements. C. A. Pierlé. J. Ind. Eng. Chem., 1920, 12, 60–63.

THE more common methods of determining uranium have been critically examined. Good results were obtained by adding ammonia solution to uranium nitrate solution, boiling the solution containing the precipitate for 15 mins., separating the precipitate, washing it with 2% ammonium nitrate solution, and drying and igniting it in a porcelain crucible. Precipitation of the uranium as uranyl ammonium phosphate by means of ammonium dihydrogen phosphate (Kern, this J., 1901, 1144) was found to be difficult, owing to the tendency of the precipitate to pass through the filter paper and to the readiness with which uranyl pyrophosphate absorbs moisture. Precipitation as uranium sulphide, and ignition of the precipitate after washing with hot 2% ammonium nitrate solution, invariably gave too high results owing to part of the sulphur being oxidised to sulphate during the ignition. The volumetric determination of uranium by means of potassium

permanganate, using Kern's modification (*loc. cit.*), also gave high results, owing to the reduction being carried below the quadrivalent condition of the uranium. A method for separating uranium from molybdenum, vanadium, and tungsten has been based on the fact observed by Peligot (Ann. Chim. Phys., 1842 [3], 5, 1) that uranyl nitrate is readily soluble in ether. Another method for separating uranium from vanadium depends on the fact that acetic acid of 95% or over when mixed with nitric acid (sp. gr. 1.42) in the proportion of 20 vols. to 1 vol. HNO_3 does not dissolve vanadium pentoxide, but readily dissolve vanadium nitrate.—C. A. M.

PATENTS.

Analysing gases [determining carbon dioxide in flue gases]; Absorption apparatus for —. P. R. Beulton, Birmingham. Eng. Pat. 136,992, 10.4.19. (Appl. 9136/19.)

A PORTABLE apparatus for analysing gases consists of a reciprocatory pump, desiccating, absorption and gauge chambers, an indicating gauge, and a controlling valve, so arranged that a sample of dry gas drawn in by the pump is discharged from one side of the piston, through the absorbent to the opposite side, which communicates with the gauge chamber. The displacement of the piston required to restore the initial pressure in the gauge chamber, or the pressure produced in the latter, is employed as a measure of the constituent to be determined.

I.—GENERAL; PLANT; MACHINERY.

Recuperative furnace; A new type of —. W. Rosenhain and E. A. Coad-Pryor. Trans. Ceram. Soc., 1918-19, 18, 407-419.

AN experimental cylindrical recuperative gas-fired crucible or glass-pot furnace for temperatures above 1500° C., with natural draught, shown in horizontal

section in the fig., is 24 in. in diameter, 18 in. high internally, and contains 20 carborundum tubes each 4 ft. long and 1½ in. diameter. The air used for combustion passes through the carborundum tubes into a collecting chamber, C, thence, past baffles, D, into a mixing chamber, E, where it meets coal gas entering through three burners, F. The flame developed in E passes around the crucible, through the flue, G, into the recuperator and thence to the chimney. A highly-successful furnace on the same principle for testing refractory materials consists of a chamber 20 in. high with a floor, 2 ft. 9 in. wide and 1 ft. 6 in. deep, across which the flame passes horizontally and then downwards and through the recuperator which is at a lower level, the exit gases being compelled by three baffles to take a long zig-zag course around the carborundum tubes. The tubes are arranged in nine courses, each consisting of 13 tubes, each tube consisting of 4 shorter tubes 8 in. in length. The tubes and baffle walls are not tied in any way, so as to allow for expansion and contraction. A temperature of 1650° C. is readily attained in this furnace. The furnace consumes 600 cu. ft. per hour of town's gas of 500 B.Th.U. The air enters the furnace at 200°-300° C. below the furnace temperature. Magnesite bricks are quite unsuitable for lining the furnace; zirconia bricks are better but spall badly. Good firebricks washed over with a mixture of carborundum and china clay are satisfactory and easily renewed after 5 or 6 heats. The draught is created by a chimney stack less than 35 ft. high.—A. B. S.

Heating autoclaves by means of an oil burner. F. Muller. Chem. Weekblad, 1920, 17, 34-35.

THE heating arrangement consists of a laterally placed furnace of sheet iron lined with firebricks and having a small interior bridge of the same material, and a burner with two orifices of 2 mm. diam. which is supplied with oil and compressed air reduced to a pressure of 1½ atm. The autoclave is enclosed in an oil bath around which the burner gases circulate in two spiral paths. Cleaning doors are provided in the brick setting. A thin tar oil is used as fuel. The burner flame must be regulated so as to impinge on the furnace bridge, and must not extend beyond the furnace. To mitigate the effect of a possible explosion of oil vapour and air in the flues, produced by choking in the burner, the cleaning doors should not be clamped too tightly. The autoclave may be rapidly cooled by circulating the oil through a cooler.—W. J. W.

Cooling liquids in spray systems and cooling towers. E. M. Baker. Chem. and Met. Eng., 1920, 22, 173-176.

THE principle on which the various forms of spray systems and cooling towers are based is to bring the hot liquid into contact with cool air, cooling being effected by exchange of sensible heat and by evaporation of some of the water, thus removing some heat in the latent form. In general, most of the cooling is due to the latter effect, and in practice the amount of cooling is determined almost entirely by the extent of evaporation. The design of a cooling apparatus should aim to give complete saturation of the exit air and to discharge the air at as high a temperature as possible, as the partial pressure due to water vapour increases rapidly with increase in temperature. The cooling effect will always be increased by increasing the quantity of air, but the extent of the increase diminishes as the temperature of the exit air is reduced. The results of a series of tests on the "Ceco" spray system under varying conditions are described and illustrated by means of graphs. (See also this J., 1920, 179 A.)—C. A. K.

Refrigerating-machines. M. Ponchon. Chim. et Ind., 1920, 3, 24-27.

A REFRIGERATING machine consists essentially of a compressor, condenser-cooler, and evaporator-refrigerator, and is a device for transferring units of cold ("frigories") from the cooling water to the liquid to be cooled. Various tables and curves are given showing the effect of the temperature of the cooling water on the refrigerating efficiency and the power absorbed. By the addition of a pre-cooler through which the cooling water passes on its way to the condenser the temperature of the liquid to be cooled is brought nearer to that of the cooling water, and it is shown that an economy of power and greater efficiency may thus be attained. This, however, is only advantageous when the supply of cooling water is limited, but when this is the case the economy is considerable.—W. H. C.

PATENTS.

Drying apparatus. E. L. A. Savy, Paris. Eng. Pat. 123,984, 26.2.19. (Appl. 4856/19.) Int. Conv., 30.11.16.

THE apparatus is intended especially for substances such fruits, vegetables, and gelatinous or fine-grained pasty substances that are best dried in a current of warm, moist air in order to prevent the formation of a hard, dry shell which prevents escape of moisture from the interior. The material is placed on trays in a chamber through which air is passed after being heated (preferably by a steam coil). Most of the air is continuously circulated by means of a fan placed between the dryer and the heater, but a portion is allowed to exhaust to the atmosphere, and fresh air, which has been deprived of its moisture by cooling, is admitted to take its place. The regulation of these two quantities of air is effected by two dampers, one between the dryer and the suction of the fan which is regulated to produce a slight pressure in the dryer, and another in the inlet pipe for additional air.

—B. M. V.

Drying granular and other substances. J. J. Krüger, Copenhagen. Eng. Pat. 137,631, 5.2.19. (Appl. 2858/19.)

TRAYS which can be tilted are arranged one above the other within a tower, and heat is applied from heating elements arranged in the spaces above and below the trays. The material is fed in through a trap door at the top, and air is passed upwards through the tower. When the material in the

bottom tray is sufficiently dry the trays are tilted in succession from the bottom upwards, so that the contents of the lowest tray are discharged, and the contents of the other trays fall one step in succession, a fresh charge being admitted to the top tray. By operating the trays by mechanical means the process is made continuous.—B. M. V.

Drying machine [for clay]. De W. D. Irwin, Assignor to E. M. Knowles, East Liverpool, Ohio. U.S. Pat. 1,329,082, 27.1.20. Appl., 21.7.19.

THE material is carried by means of an endless conveyor through a horizontal drying chamber which is provided along the top and along at least one vertical side with openings which can be closed. A current of air is supplied through a chamber open at the bottom, which may be moved longitudinally along the top of the drying chamber so as to communicate with it through any desired openings. The material at any desired point may thus be subjected to the air current for any required length of time.—W. F. F.

Packing materials [resistant to chlorine] and processes for making the same. C. F. Wallace, New York, and M. F. Tiernan, Jamaica, N.Y., U.S.A. Eng. Pat. 131,871, 7.4.19. (Appl. 8797/19.) Int. Conv., 28.8.18.

A PACKING material, suitable for use in apparatus in which chlorine is employed, is made by dissolving beeswax in carbon tetrachloride and saturating asbestos string or rope with the solution. Graphite flake or powder is then incorporated with the asbestos and the solvent evaporated. The material may be wound around valve stems.—W. F. F.

Volatile solvents; Process for the collection and recovery of — evaporated into the atmosphere. L. A. Levy, London. Eng. Pat. 137,615, 27.1.19. (Appl. 1940/19.)

THE vapour-laden air is passed through one of two vessels containing active charcoal which absorbs the vapour; when the charcoal in one vessel has absorbed sufficient the air is passed through the other vessel, and the first one heated to recover the volatile solvent.—B. M. V.

Vapours [of volatile solvents]; Process for recovering — from air mixtures by sulphuric acid. A. Lehner, Berlin-Tempelhof. Ger. Pat. 303,396, 10.9.16.

THE process is applicable to the recovery of alcohol and ether from the air of explosives and artificial silk works. The air is passed through towers in series. The enriched acid from the lowest tower is withdrawn at intervals, e.g., by a siphon or pump, and the chamber filled with acid from a higher tower.—H. J. H.

Gas-fired [crucible] furnaces. J. W. Gaunt, and W. and J. Lawley, Ltd., West Bromwich. Eng. Pat. 137,628, 5.2.19. (Appl. 2778/19.)

A GAS-FIRED crucible furnace is built up in horizontal sections by two or more fire-brick annuli placed one on top of the other, so that the resulting chamber conforms to the shape of the crucible used. The bottom brick in addition has lateral ports for the entering gas flames, and the uppermost one an opening, preferably lateral, for the outlet of products of combustion. At points of local intense heat, blocks of a more refractory material, e.g., carborundum, may be inserted in the firebrick.

—B. M. V.

Combustion of gases in boiler furnace flues or tubes: Means for completing or promoting the —. W. Hassall, Woodville. Eng. Pat. 137,770, 18.8.19. (Appl. 20,307/19.) Addition to 128,325 (this J., 1919, 611 A).

IN order to ensure the more effective withdrawal

of the burnt dust from the flue, the block placed in the flue is tapered longitudinally, so that the annular passage is gradually restricted.—W. P.

Furnaces; Reversible gas-heated —. F. T. Renison, Sheffield. Eng. Pat. 137,977, 25.4.19. (Appl. 10,307/19.)

WITH the reversing valves in the position shown in the figure, air enters behind the reversing air valve, r, passes up the pipe, b, down the chimney,

a, to the longitudinal flue, c, in which it travels the full length of the furnace, then across to flue, c¹, again along the furnace, across to side flue, e, down which it passes to four (or other number of) transverse flues, h, to vertical passages, j¹, opening at the side of the hearth proper. The walls, e¹, e², of the side flues, e and i, are tied with bricks which are staggered so as to break up the incoming air or outgoing gases; some of these bricks, f, f¹, are formed with gas conduits in them supplied from a gas main behind the valve, m, and with the valves in the position shown the gas conduit-bricks, f, are shut off, while the conduits in f¹ are supplying gas which meets the heated air in j¹. Combustion takes place under the arch and the gases pass by vertical passages, j, down to transverse flues (not shown), which alternate with flues, h, then up through the side flue, i, twice along the furnace in c² and c³, and out to the atmosphere through the chimney, a¹, the valve-cap, a², of which is open.—B. M. V.

Grinding mills. O. Soder, Niederlenz, Switzerland. Eng. Pat. 137,640, 13.2.19. (Appl. 3582/19.)

IN a mill for fine grinding consisting of a grinding roller working against a grinding block, the latter is divided into segments in the direction of its width, the several segments being pivoted upon a pin which lies below the blocks (the roller running downwards as usual) and outside the angle subtended by the blocks to the centre of the roller; the object of this is that the grinding slot may taper, becoming narrower in the direction of rota-

tion. The pivot rod should be placed in such a position that the resultant of the frictional forces between the grinding blocks and roller passes through or near it; the upper edges of the grinding blocks are situated at about the point on the roller where the material would leave the latter due to centrifugal force. The grinding roller may be built up of an inner cast drum and outer grinding segments with a layer of heat insulating material between.—B. M. V.

Furnace setting. F. H. Nickle, St. Louis, Mo. U.S. Pat. 1,329,470, 3.2.20. Appl., 1.7.18.

A CONTAINER to be heated is supported in a furnace setting composed of firebrick and having concentric chambers as shown. A combustible mixture

is supplied to the intermediate annular chamber where it is burnt, and the combustion products pass through the openings, 6, to the annular chamber, 7, and thence through the space, 10, to heat the container. The gas then passes downwards through the annular space, 11, to the passage, 16, leading to the stack, 17.—W. F. F.

Refrigerating apparatus. B. E. D. Kilburn, London. From Sulzer Frères, Winterthur, Switzerland. Eng. Pat. 137,975, 23.4.19. (Appl. 10,157/19.)

The apparatus is of the type in which the vapour of the refrigerating agent is removed from the refrigerator and compressed in an ejector by means of another working fluid circulating through the ejector, a cooler, and a pump. The refrigerating vapour is not cooled sufficiently to condense in the first cooler, but is there allowed to separate as vapour by gravity from the working fluid, and then condensed in a second cooler or condenser, whence it passes through an expansion valve back to the refrigerating coil. The same cooling water may be passed through the condenser and the cooler for the working liquid in succession. The whole apparatus (except the driving motor) may be contained in a double tank, and if a refrigerating agent is used which is lighter (when liquid) than the working fluid, a small passage may be provided from the bottom of the condenser portion of the tank to the working-fluid cooler, so that any spray of working fluid carried over into the condenser can flow back to its proper compartment. A special form of ejector is described in which the suction chamber is made large enough to collect the small quantity of working fluid contained in the nozzles, so that when the apparatus is stopped the working fluid does not flow into the refrigerator and become frozen there.—B. M. V.

Separator; Centrifugal — [for crude oil]. W. S. Estep, Cleveland, Okla. Assignor to R. V. Henry, Augusta, Kans. U.S. Pat. 1,307,000, 17.6.19. Appl., 20.4.18.

The apparatus is intended more particularly for separating foreign substances, such as particles of water, from crude mineral oil. The separating vessel is a closed cylinder rotating on its vertical axis, and the oil is supplied through a pipe which is fixed vertically in the axis of the vessel, and is provided with a number of radial discharge pipes terminating near the outer wall of the cylinder. The

bottom of the vessel is dished inwards in the form of a large cone projecting upwards to about two-thirds of the height of the vessel, and the resulting annular space is provided with large radial ridges projecting from the surface of the cone and each formed of two sloping plates forming an inverted V-shape in vertical cross-section. The outlets of the radial supply pipes are arranged above the radial troughs thus formed. As the result of centrifugal action the heavier impurity collects at the bottom of the vessel at its outer periphery, and the lighter clarified oil collects at the top and overflows into a central vertical discharge pipe surrounding the vertical shaft. The radial baffles prevent the impurities from collecting in a single mass, and thus destroying the balance of the vessel.—W. F. F.

Separator; Centrifugal — P. T. Sharples, St. Davids, Pa. U.S. Pat. 1,320,119, 4.11.19. Appl., 29.10.18.

The liquids to be separated are contained in the rotating bowl, 3, which is provided at the top with a concentric ring, 8, having internal and external knife edges over which the lighter and heavier constituents respectively are discharged. The lighter constituent passes through the passage, 10, into the receptacle, 11, and the heavier constituent passes through the passage, 12, and over the weir, 9, into the receptacle, 14. Wings, 18, are provided to rotate the liquid with the bowl. This construction is adapted to maintain a constant ratio between the constituents in the separator, notwithstanding variations in the viscosity of the constituents and in the quantities discharged. The weirs, 8 and 9, are detachable, and may be replaced by others of different proportions.—W. F. F.

Centrifugal machines. E. D. Mackintosh, Brooklyn, N.Y., Assignor to S. S. Hepworth Co. and E. M. Mackintosh, New York. U.S. Pats. (A) 1,321,766 and (B) 1,321,767, 11.11.19. Appl., 30.10.18.

(A) The bottom of the centrifugal basket, *b*, consists of an inner part, *a*, sliding on the inner sleeve, *f*, and an outer frustum of a cone, *c*, the outer edge

of which is normally in contact with the lower rim, *t*, of the side wall, *b*, to close the basket. The bottom is pressed upward by a pair of toggle levers, *o*, *p*, controlled by a spring, *r*, which tends to open them and force the basket upwards, the centrifugal force also tending to open the toggles. The material to be treated is dropped on to the disc, *t*, and the solid matter is thrown on to the perforated side wall, *b*, where it collects in a layer. On stopping

the basket the solid matter by its weight forces the bottom down and is thus discharged. The bottom closes again when the basket is rotated. (b) The vertical spindle of the machine is driven from the vertical rotating shaft of a motor through a universal coupling member. The vertical shaft carries a T-shaped head, to the ends of which a frame having a depending lug at each end is pivoted to swing about the horizontal axis of the T-piece. The ends of the depending lugs engage freely with lugs projecting from a headpiece carried by the spindle of the centrifugal machine, and the headpiece rotates on ball bearings carried by a cup-shaped member which is non-rotatable, but which is supported in a spherical socket in a fixed support. The spindle of the centrifugal machine is thus free to swing slightly in any direction.

—W. F. F.

Filter-press devices. G. F. Miller, New York. U.S. Pat. 1,313,318, 19.8.19. Appl., 31.3.19.

THE filter-press is of the type in which there are two heads connected by side bars, and a movable follower operated by a screw from one of the heads to press together the filter elements, which slide on the side bars. The object is to improve the connexion between the side bars and the heads. Each bar is of channel section and fits into a recess in the side of the head. A longitudinal reinforcing block fits into each end of the channel and is provided with a T-piece overhanging the end of the channel bar. The head carries a stud which projects through a slot in the bottom of the channel bar and also through the reinforcing block, and the parts are secured against detachment by a small transverse plate screwed to the head.—W. F. F.

Drum-filter wiring. E. S. Pettis, Mill Valley, Cal. U.S. Pat. 1,327,962, 13.1.20. Appl., 5.3.19.

A FILTERING drum is surrounded by filtering material, and this in turn by a series of circumferential wires. A pair of bars are arranged on the periphery of the drum, parallel to the axis and close together, and the two ends of all the circumferential wires are attached to the two bars respectively.—W. F. F.

Hydrocarbon filter. Multistage adjustable filtering apparatus. Unitary multistage filter apparatus. H. A. Hills, Grand Rapids, Mich. U.S. Pats. (A) 1,328,044, (b) 1,328,045, and (c) 1,328,046, 13.1.20. Appl., (A) 23.7.16, (b, c) 7.5.17.

(A) A HORIZONTAL cylindrical casing is provided with a number of internal filter elements each in the form of a coaxial frustum of a cone, the cones being nested one within the other. The compartments thus formed are provided with outlets at the bottom leading to receptacles below, having transparent walls. An inlet for the unfiltered material is provided at one end of the casing and an outlet for the final filtrate at the other end. The filtering elements are mounted on an axial rod so as to be readily detachable. (b) A number of receptacles containing filtering material are provided with pipe connexions whereby the liquid to be filtered may be passed in succession upwards through the filtering material in each receptacle. Any one of the receptacles may be cut out of the series when desired. (c) The filters described in (b) are arranged in adjacent compartments in a single casing, and a heating device is provided in the bottom of each compartment.—W. F. F.

Evaporator. W. E. Garrigue (J. C. Guenther, administrator, Chicago, Ill.), Assignor to W. Garrigue and Co., Inc., New York. U.S. Pat. 1,317,488, 30.9.19. Appl., 19.2.19.

THE apparatus is of the type in which solutions to be concentrated are heated in a vertical tubular heater by means of superheated steam around the

tubes. The liquid is caused to circulate upwards through the central tubes and downwards through the outer tubes into a space below the lower tube-plate. The bottom plate of this space is concave, and is provided with a central tube leading downward to another vessel. The liquid moving radially over this plate sweeps any crystals formed into the outlet pipe, from which they pass to the vessel below. The vapour rises upwards from the tubes into a chamber above and passes into a separator at a higher level, and thence to a condenser. The bottom of the condenser is connected by a vertical tube of barometric height to an open collecting vessel, forming a liquid seal at the bottom, so that the vacuum is maintained in the system. When desired, liquid from the collecting vessel may be drawn by suction into the lower part of the evaporator through a valved pipe dipping into the liquid.—W. F. F.

[Evaporating] materials; Apparatus for treating —. C. R. Mahee, Toledo, Ohio. U.S. Pat. 1,329,786, 3.2.20. Appl., 23.10.15.

THE material is maintained in continuous movement over the inner cylindrical surface of a fixed horizontal cylinder by means of rotating baffles close to the surface. The cylinder is heated by means of an external jacket and the vapour from the treated material is withdrawn through an adjustable valve at the end of the cylinder, the valve being normally closed.—W. F. F.

Liquids; Process of concentrating —. G. T. Walker, Assignor to Colonial Chemical Co., Minneapolis, Minn. U.S. Pat. 1,330,016, 3.2.20. Appl., 17.6.18. Renewed 19.5.19.

THE liquid to be concentrated is mixed with an anhydrous salt capable of forming crystals containing water of crystallisation, and heated to the temperature at which the solubility is greatest. The solution is stirred until saturated and then cooled, when crystals are deposited, containing some of the water in the solution, which is thereby concentrated.—W. F. F.

Cooling liquids; Means for —. J. Hutchinson, Brooklyn, N.Y. U.S. Pat. 1,327,560, 6.1.20. Appl., 16.9.18.

LIQUID and gas chambers, each provided with baffles, are arranged adjacent to one another in heat-exchanging relation. Successive charges of compressed gas are expanded in the gas chamber, thereby falling in temperature and cooling the liquid, and each expanded charge is expelled before the next compressed charge is admitted.—W. F. F.

Conveyor. B. A. Parkes, Assignor to The Philadelphia Drying Machinery Co., Philadelphia, Pa. U.S. Pat. 1,328,099, 13.1.20. Appl., 8.10.17.

A SERIES of horizontal endless band conveyors are arranged one above the other, and each is composed of sections which are adapted to receive material on one face only. Each section is inverted as it approaches the end of its upper horizontal travel, and the material is transferred from it to the returning lower part of the conveyor. The inverted sections are re-inverted as they enter their lower horizontal travel, to receive the material as it falls from the upper part of the conveyor.—W. F. F.

Mixer. L. M. Brayman, Westville, N.H. U.S. Pat. 1,328,119, 13.1.20. Appl., 27.2.19.

THE mixer consists of a barrel of polygonal cross-section mounted to rotate with its axis horizontal. The angles between each end wall and the adjacent side walls are cut off within the barrel by inclined plates secured to both walls and joined to one another at their ends. The material in the barrel is thus directed away from the ends during rotation.—W. F. F.

Mixing concrete ingredients or other substances; Machines for —. F. W. Kiddie, Leamington. Eng. Pat. 137,901, 17.1.19. (Appl. 1281/19.) Addition to 124,112.

Electrical treatment of gases; Method and apparatus for —. L. Bradley, East Orange, N.J., Assignor to Research Corporation, New York. U.S. Pat. 1,329,825, 3.2.20. Appl., 21.6.16.

Catalytic agents for reduction or hydrogenation purposes; Process for producing —. A. Radisson (Assignor to Soc. de Stearinerie et Savonnerie de Lyon) and P. Berthon, Lyon, France. U.S. Pat. 1,330,003, 3.2.20. Appl., 18.5.17.

SEE Eng. Pat. 107,004 of 1917; this J., 1918, 431 A.

Drying, conditioning, and regulating the moisture content of hygroscopic materials; Method of and apparatus for —. W. H. Carrier, Assignor to Buffalo Forge Co., Buffalo, N.Y. U.S. Pat. 1,330,238, 10.2.20. Appl., 3.6.18.

SEE Eng. Pat. 121,080 of 1918; this J., 1919, 61 A.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Washing of —. A. Moreau. Rev. Mét., 1919, 16, 416—435.

In French practice, coal passing a 50—60 mm. screen is sent to the washery. It can be divided into two fractions, i.e., fine coal passing through a 10 mm. sieve, and the residue left on the sieve. The washing of the coarser portion can be controlled by visual inspection, but in the case of the finer material it is necessary to wash to a pre-arranged ash content, based on the constitution of the coal and on the terms of the coal specification. The author discusses from the mathematical standpoint the washing of this finer material.—A. G.

Wood charcoal; Combustion of — with nitric acid. F. C. G. Müller. Z. angew. Chem., 1920, 33, 40.

Wood charcoal was heated in a closed tube in a current of nitric acid vapour, and the resulting gases were collected and analysed. In three experiments the following results were obtained:—CO₂, 52.2—57.2; CO, 13.3—14.7; H₂, 3.4—4.6; N₂, 24.9—26.7%. The high CO content and the presence of free hydrogen are noteworthy. The liquid condensed from the issuing gases contained a considerable quantity of ammonia, the presence of which is difficult to account for, as the reaction temperature was certainly not less than 1000° C.

—E. H. R.

Carbon monoxide; Direct formation of — by burning carbon in pure oxygen. F. C. G. Müller. Z. angew. Chem., 1920, 33, 36.

A QUARTZ or hard-glass tube, 25 cm. long and not more than 13 mm. in diameter, is fixed in a vertical position and filled with pieces of charcoal of the size of linseed; the upper end of the tube is connected to a gas-holder containing oxygen and the lower end to a reservoir containing water. After the upper part of the tube has been heated with a burner, the tap on the oxygen holder is opened so that water flows from the lower reservoir at the rate of 2 litres per minute. It is important that a reduced pressure be maintained in this way in the tube. The gas collecting in the lower reservoir will contain 85% of carbon monoxide.—W. P. S.

Carbon; Combustion of —. F. C. G. Müller. Z. phys.-chem. Unterr., 1919, 32, 40—45. Chem. Zentr., 1919, 90, IV., 1120.

By burning charcoal in a stream of oxygen a considerable quantity of carbon monoxide is formed in addition to carbon dioxide, the quantity being greater the higher the temperature (see preceding abstract). The laboratory preparation of water-gas in a glass tube can be carried out in a combustion furnace at 800° C.; in three minutes 900 c.c. of gas was obtained having the composition CO, 23.4; CO₂, 10.8; H₂, 5.3; CH₄, 2.1%; and N₂, 4.8%. —B. V. S.

Liquid fuels; Spontaneous ignition-temperatures of —. H. Moore. Inst. Petroleum Tech., Jan. 20, 1920. [Advance proof.]

EXPERIMENTS with industrial liquid fuels in the apparatus previously described (this J., 1917, 109) showed that the results are not substantially affected by alteration in the rate of fuel and air or oxygen supply, by dilution of the oxygen with carbon dioxide, or by using crucibles of different materials, e.g., silica, platinum, nickel, or porcelain. The ignition-temperature in air was generally from 80° to 200° C. higher than in oxygen, the notable exception being turpentine, which yielded the same result in both atmospheres, viz., 275° C. The ignition-temperature of pure hydrogen in air was 686° (porcelain crucible), 619° (nickel do.), and 678° (silica do.) respectively, and the ignition-temperature in oxygen is given as 678°, 680°, and 677° respectively in three determinations. A number of observations were recorded on the ignition-temperatures of binary mixtures from which it was concluded that in a mixture consisting mainly of a liquid of high ignition-temperature, the addition of a small amount of liquid of low ignition-point has very little effect on the ignition-point of the mixture and *vice-versa*. In internal-combustion engines, whether of the two-stroke or four-stroke cycle, and whether operating upon the constant-pressure or constant-volume cycle, the theoretical thermal efficiency is dependent on the compression ratio. The bearing of the above observations on the limiting compression pressure allowed for a specific fuel is discussed.—A. G.

Refractories for coke ovens. W. J. Rees. Gas World, 1920, 72, Coking Sect., 9—11.

BRICKS used in coke ovens seldom attain a higher temperature than 1350° C., even in the heating flues, and the load on them is not sufficient to lower their refractoriness seriously. The corrosion of the bricks appears to be largely due to soluble salts—especially sodium sulphate and chloride—in the coal (see also following abstract). Sodium chloride volatilises at 800° C., hydrolyses at 700° C., and at these or somewhat higher temperatures it attacks the bricks forming a glassy sodium aluminium silicate and making the bricks weak, spongy, and of low resistance to abrasion. The action of hydrochloric acid (from hydrolysed salt) on iron oxide appears to result in the production of layer upon layer of hematite in the bricks; this brings about a different coefficient of expansion in some parts of the bricks and leads to rupture on heating and cooling. Corrosion by salt is more severe in ovens built of fireclay than in those built of silica bricks, partly as a result of direct action and partly due to the fireclay bricks shrinking in use and so causing open joints which expose a greater area to attack. Silica bricks, on the contrary, tend to expand and so cause serious stresses in the structural work of the oven. Suitable natural or artificial mixtures of silica and fireclay produce bricks which neither shrink nor expand. Fireclay bricks burned so as to produce a large percentage of sillimanite may prove

to be highly resistant to the salts in some coals. The catalytic effect of fireclay on hydrocarbons produced during coking with the resultant deposition of carbon in the pores of the brick and the reduction of ferric oxide with the formation of easily fusible ferrous silicate may also assist the disintegration of the bricks. Le Chatelier's work on the use of impalpable silica (this J., 1917, 963) is quoted, and the use of silica rock which gives angular fragments with 25% of impalpable silica powder is recommended. The higher thermal conductivity of (American) silica bricks compared with that of bricks made of or containing much clay is in favour of the use of silica bricks for coke-oven construction.—A. B. S.

Coke oven walls; Corrosion of — W. J. Rees. Trans. Ceram. Soc., 1918-9, 18, 431-434.

THE water used for washing a coal which seriously corroded coke-oven walls was found to contain sodium sulphate as well as sodium chloride, and it is suggested that the former may react with the coal, forming sodium carbonate which is a vigorous corrosive agent.—A. B. S.

Carbon in furnace refuse; Loss due to — C. H. Berry. Power, 1919, 500. Chem. and Met. Eng., 1920, 22, 179.

THE loss of heat due to the presence of carbon in furnace ashes depends upon the percentage of ash in the original coal and the percentage of carbon in the ash. Lb. carbon lost per lb. coal fired =

$$\frac{\% \text{ ash in coal}}{100} \times \frac{\% \text{ C in ash}}{100 - \% \text{ C in ash}}$$

Under fair working conditions not more than 20% of carbon should be present in the furnace ashes, and under good conditions not more than 10%. The corresponding heat losses will then be less than 5% and may be as low as 1%. A series of tests conducted by the U.S. Geological Survey under working conditions showed an average heat loss of nearly 5%. Practical suggestions with a view to reducing the loss include the avoidance of unnecessary raking, an ample supply of air at the dump plate, and the use of clinker grinders.—C. A. K.

Semi-coke obtained by low temperature carbonisation of coal. F. Fischer and W. Glud. Ges. Abhandl. Kenntn. Kohle, 1919, 3, 215-226. Chem. Zentr., 1919, 90, IV.; 880-881.

SEMI-COKE from low-temperature carbonisation ignites readily and burns easily without smoke, but with some flame—mainly of hydrogen. Lohberg coal gave a semi-coke with 15-16% of volatile matter. The specimen tested was not hygroscopic. It contained 1.9% N (on the ash- and moisture-free residue), corresponding to two-thirds of the nitrogen content of the original coal; when heated above 575° C. it gave up one-third of its nitrogen as ammonia. Heated in a current of steam almost the whole of the nitrogen was liberated as ammonia. The sulphur contents of the ash- and moisture-free residues of coal and coke are the same. The oxygen content fell from 8.7 in the coal to 7.5% in the coke, this being in accord with the yield of phenolic substances. The only serious shortcoming of the semi-coke is its friability, but this varies with the class of coal carbonised—some yielding a satisfactory coke (cf. F. Fischer, this J., 1920, 93 A). For use as powdered fuel this should even be an advantage.

—H. J. H.

Vegetable tissues; Extraction of — with dry and moist benzene under pressure. F. Fischer and M. Kleinstück. Ges. Abhandl. Kenntn. Kohle, 1919, 3, 301-314. Chem. Zentr., 1919, 90, IV., 940-941.

EXTRACTION experiments were made with various

kinds of wood, lignite and a similar material from Japan (*Umoregi*), peat, fern, shave grass, straw, pine needles, foliage leaves, and beech bark. Extraction with benzene under pressure at 250° C. gives far higher yields of extract than the ordinary method with a Soxhlet apparatus, e.g., in the case of pine wood 16.2% instead of 0.24%. At lower temperatures the yields are not so great, but they can be increased by the use of another suitable solvent. The extracts obtained under pressure, from wood, are at the ordinary temperature brownish-black shining solids, which can usually be softened by the warmth of the hand. They are soluble in chloroform, acetone, pyridine, acetic acid, and acetic anhydride, less soluble in ethyl and methyl alcohols, ammonia, potassium hydroxide, ether, and carbon tetrachloride, and only slightly soluble in light petroleum spirit. All give a strong lignin reaction and contain manganese. In water they become dull and grey; the aqueous extracts reduce ammoniacal silver solution, usually in the cold, and Fehling's solution on warming. Extracts made under pressure, from the other materials, show a strong green fluorescence in benzene solution. Those from peat, pine needles, straw, and foliage and fern leaves have a waxy appearance and are almost completely soluble in ether and carbon tetrachloride. Extraction with benzene under pressure in presence of water was found in many cases to give higher results than with benzene alone, though the matter extracted was entirely soluble in benzene. In the aqueous portion formic and acetic acids, formaldehyde, and acetaldehyde were detected. By a single extraction with water alone, at 250° C., yields of extract amounting to 83% in the case of poplar wood, and 85% in the case of beech wood were obtained; besides acetone and acids, catechol, furfural, formaldehyde, and acetaldehyde were present in the extracts.—J. H. L.

Lignite; Influence of the moisture-content of — on the yields of extract obtained with benzene in Soxhlet apparatus and under pressure. F. Fischer and W. Schneider. Ges. Abhandl. Kenntn. Kohle, 1919, 3, 315-324. Chem. Zentr., 1919, 90, IV., 935.

IN extracting lignite with benzene in a Soxhlet apparatus higher results are obtained in operating on an air-dry sample containing 10-20% of moisture than with a sample previously dried at 105° C., e.g., 15% of extract in the former case and 11% in the latter. Still greater differences are found in extracting with benzene under pressure at 240° C. The higher yields obtained in presence of moisture are not due to higher contents of water, ash, or humic acids in the extracts.—J. H. L.

Gaseous explosions; Calculation of radiation emitted in — from the pressure-time curves. W. T. David. Phil. Mag., 1920, 39, 66-83.

FROM an examination of a large number of photographic films on which were traced curves of pressure and of radiation emitted in explosions of inflammable mixtures of coal gas and air (this J., 1919, 707 A, 807 A) some simple equations have been established which would seem to apply within fairly wide limits of composition, density, and volume of the mixture. In mixtures containing from 9.2 to 15% of coal gas and at pressures varying from 0.5 to a little over 1.5 atm., the rate at which the walls receive radiation is at a maximum some little time before the attainment of maximum pressure, and this maximum rate is proportional to the square root of the product of the maximum rate of change of the mean gas temperature and the quantity of coal gas present in the explosion vessel measured at atmospheric temperature and pressure. The effect of variation in the size of the explosion vessel and the density of the gas mixture upon the rate and total amount of radiation is examined, and the

rate of emission of radiation during cooling discussed. The conditions governing the emission of radiation in gaseous explosions are exceedingly complex and the formulae set up, though useful as a basis for gas-engine calculations, can only be relied upon to give results correct to within 10–20%.—W. P.

Gaseous explosions; Analysis of the radiation emitted in —. W. T. David. *Phil. Mag.*, 1920, 39, 84–95. (See preceding abstract.)

From an analysis of the radiation emitted during explosion of mixtures of coal-gas and air and hydrogen and air, conclusions are drawn as to the origin of the radiation, and a theory is formulated as to the distribution of energy.—W. P.

Thermal efficiencies of production, distribution, and use of gas and electricity. D. Clerk. *Gas J.*, 1920, 149, 294–296.

A REPLY to criticisms advanced against a previous paper (this J., 1919, 104 B). The figures given were obtained by calculations based on the assumption of the lowest efficiency figure that can be adopted for coal gas generation, the gaseous product of carbonisation being debited with the whole of the heat employed in the carbonisation process.—J. S. G. T.

Viscosity of gases. M. Hofsäss. *J. Gasbeleucht.*, 1919, 62, 776–777.

THE viscosity of complex gas mixtures, such as coal gas, cannot be accurately calculated from their composition. An apparatus is illustrated which may be used for the determination of the viscosities of mixtures of illuminating gas and other gases relative to the viscosity of air by measuring the rate of flow through a fine capillary. Curves are given showing the viscosities relative to air of mixtures of coal gas with from 0 to 100% of hydrogen, methane, carbon dioxide, nitrogen, carbon monoxide, and air. Curves are likewise given showing the viscosities of mixtures in various proportions of methane and air, hydrogen and carbon dioxide, hydrogen and nitrogen, hydrogen and oxygen, and helium and argon, the three latter mixtures at 0° C., the remainder at 15° C. The following table gives the relative density, relative viscosity, and relative viscosity modulus (relative viscosity: relative density) of various gases, in each case relative to air:—

	Illuminat- ing gas.	Carbon mon- oxide. Nitrogen	Carbon dioxide.	Ethy- lene.	Benzene.
Relative density ..	0.595	0.967	1.520	0.967	2.694
Relative viscosity ..	0.738	0.965	0.840	0.574	0.417
Relative viscosity modulus ..	1.240	1.00	0.553	0.593	0.155

The viscosity of a gas affords valuable information concerning the purity of the gas.—J. S. G. T.

Coal-gas; Influence of carburetting of — on the crystallisation of naphthalene in the mains. C. Ab-der-Halden. *Chim. et Ind.*, 1920, 3, 19–23.

To determine the influence of carburetting agents on the amount of naphthalene retained in the gas at various temperatures, coal gas, saturated with naphthalene at a definite temperature, was carburetted with known amounts of various carburetting agents derived from petroleum or coal-tar and then cooled until naphthalene was deposited. It was found that after the addition of the carburetting agent the gas could be cooled several degrees lower without depositing naphthalene than before such addition. The power of

holding naphthalene in "supersaturation" in the gas depended on the boiling point of the carburetting agent rather than on its constitution, and the degree of extra cooling to which the carburetted gas could be submitted without depositing naphthalene was dependent on the amount of carburetting agent added and on the degree of saturation of the gas with naphthalene.—W. H. C.

Purification; Oxide — [of coal gas; analysis of spent oxide]. G. Weyman. *Gas J.*, 1920, 149, 301.

FERRIC and ferrous sulphides are produced by the action of hydrogen sulphide upon ferric hydroxide, and the free sulphur produced by the interaction is usually taken as a criterion of the amount of ferrous sulphide formed. The sulphur content of the purifying mass may, however, be affected by many other factors than the amount of ferrous sulphide formed. The author, adopting a suggestion by L. T. Wright, determines the ratio of sulphur to iron in the mass by decomposing the sulphides with copper sulphate solution. The sulphide is freed from hydrogen sulphide by a current of hydrogen and digested for 10 minutes at 30°–40° C. with an excess of copper sulphate solution, then rapidly filtered and washed, the filter paper being kept full of liquid. The wet copper sulphide is oxidised in the original beaker with concentrated nitric acid. The solution is diluted and excess of ammonia added. The precipitate is purified by re-solution and precipitation, the washings being added to the main bulk, which is then acidified with nitric acid and a little sulphuric acid, made up to a known volume, and a portion taken for electrolysis. The filtrate from the copper sulphide is made strongly alkaline and filtered. The precipitate is purified by re-solution and re-precipitation, dissolved in sulphuric acid, diluted to a known volume, and portions taken for reduction and titration with permanganate, the reduction being best effected with a modified Jones reductor.

—J. S. G. T.

Matita asphalt; Products obtained by the dry distillation of —. C. Nicolescu-Otin. *Bull. Acad. Roumaine*, 1916–7, 5 [3], 129–138.

MATITA asphalt was distilled in stoneware or iron stills at 730° C. Compared with petroleum, the lower fractions are much less in quantity, indicating that the simple hydrocarbons of petroleum have undergone extensive polymerisation by atmospheric action aided by the exposure of a large surface due to the percolation of the petroleum in the sandy clay-beds. The tar-fractions also have saponification values much higher than those of petroleum fractions, and the presence of cyclic hydrocarbons in the tar in such striking quantities compared with the petroleum fractions indicates the change from petroleum to bitumen, the action of pressure, temperature, oxygen, and specially of time converting the saturated and unsaturated acyclic hydrocarbons into aromatic compounds. The tar products are characterised by large contents of sulphur and nitrogen. Matita asphalt gives, on distillation, a combustible gas which approaches to that from lignite in quantity and quality. About 10 kilos. of ammonium sulphate per ton of bitumen is obtained, the asphalt containing 29% of bitumen. The coke may possibly be utilised for refining petroleum in place of fuller's earth. The quantity of tar obtained is at least 120 kilos. per ton of rock asphalt, or 450 kilos. per ton of bitumen; it contains a high proportion of aromatic compounds as well as a large amount of paraffin (30% in the fraction 200°–275° C.). The asphalt could be used as a source of paraffin, vaseline, and mineral oils of superior quality.—A. G.

Paraffin wax; Technique of crystallisation in the manufacture of —. K. Fuchs. *Petroleum* (Berlin), 1919, 14, 1281—1285. *Chem. Zentr.*, 1919, 90, IV., 938—939.

PARAFFIN WAX may be made to crystallise from any (petroleum) oil or intermediate product, however viscous, if the wax-content is increased sufficiently. The lighter paraffins give the largest crystals, and require only a relatively low degree of supersaturation for crystallisation to take place. With increase of viscosity the size of the crystals diminishes (cp. Bergel, this J., 1919, 278 A). Very satisfactory crystallisation can be obtained from oil mixtures having a viscosity of 1.17°—1.8° Engler at 50° C., a setting point of 27°—30° C., sp. gr. 0.87—0.88, and a wax-content of 20—25%. The cake (*Gatsch*) of separated paraffin should be fairly free from oil, show a well-marked crystalline texture, and yield a pressed scale with a setting point of 45°—48° C. for a wax-content of 70—80%. For a satisfactory sweating process the wax-content of the scale should not be too high, and the crystals should be large in order to provide interstices for drainage. The drainings from the sweating chambers are preferably divided into three fractions: the first, of setting-point up to 32° C., is worked up again for paraffin; the second, of setting-point 32°—38°, is filtered warm together with paraffin cake (*Gatsch*), and the third, of setting-point 38° or above, is again sweated alone or together with pressed scale.—J. H. L.

Petroleum products; [Laboratory] distillation of —. F. Bordas. *Ann. Falsif.*, 1919, 12, 346—351.

A MODIFICATION of the Regnault-de Luynes apparatus is described; the condensing system is not changed, and for petroleum spirit (petrol) the original form of still is retained. For lighting oils, the de Luynes still is provided with an opening 2 cm. above the usual side tube to facilitate the introduction of thick oils and the cleaning of the apparatus; a number of perforated plates are fitted inside the still. The latter is surrounded by a jacket, the lower part of which contains a gas burner fitted with a regulating tap; the top of the burner is provided with a metallic gauze cap and a metal plate and wire gauze are placed between the burner and the bottom of the still.—W. P. S.

Montan wax; Determination of the saponification value of —. H. Salvaterra. *Chem.-Zeit.*, 1920, 44, 129.

FOUR grms. of the sample is heated under a reflux condenser for about 5 hours with 30 c.c. of *N*/2 alcoholic potassium hydroxide solution and 20 c.c. of xylene; 25 c.c. of 6.1% barium chloride solution and 250 c.c. of boiled water are then added, the mixture heated for a further one hour on a water-bath, cooled, diluted to 520 c.c., and a quantity of the aqueous layer is drawn off, filtered, and 100 c.c. of the filtrate titrated with *N*/2 hydrochloric acid, using phenolphthalein as indicator. The end-point is quite sharp, which is not the case when it is attempted to titrate the dark-coloured saponification mixture directly.—W. P. S.

Paraffin; Oxidation of —. *Oxidation of hydrocarbons by oxygen.* C. Kelber. *Ber.*, 1920, 53, [B], 66—71.

PARAFFIN, vaseline, mineral oil distillates, and the higher fatty acids may be oxidised, rapidly and almost completely, by means of a well-divided current of oxygen at 140°—150° C., especially in the presence of insoluble manganese compounds. A preliminary example is recorded. Paraffin wax of m.pt. 50°—51° C. gave 25% of a distillate containing fatty acids of the series C_1 to C_{10} , 40—50% of a residue of higher fatty acids, and 5—10% of hydroxy-fatty acids.—J. C. W.

Light petroleum and paraffin from coal. Fischer and Glud. *See* III.

PATENTS.

Pulverised fuel; Apparatus for feeding —. P. Meider, jun., Pittsburgh, Pa. U.S. Pat. 1,328,750, 20.1.20. Appl., 23.6.19.

THE pulverised fuel and the air supply pass from a main pipe into a short pipe connected therewith. Secondary air is introduced under pressure through a pipe surrounding the short pipe and extending to the furnace.—W. P.

Coal; Flotation of —. R. F. Bacon, Pittsburgh, Pa., Assignor to Metals Recovery Co., New York. U.S. Pat. 1,329,493, 3.2.20. Appl., 27.2.17.

BITUMINOUS coal is ground to give a finely divided product with particles having sharp angular edges and bright surfaces, and is then subjected to a froth flotation separation process.—W. P.

Solidified fuel. J. M. Kessler, West Orange, Assignor to The Arlington Co., Arlington, N.J. U.S. Pat. 1,329,610, 3.2.20. Appl., 28.10.16.

A SOLIDIFIED liquid fuel composition contains nitro-cellulose, a metallic powder containing copper (e.g., bronze powder), and alcohol.—W. P.

Chamber ovens; Regenerative —. A. Klönne, Dortmund. *Ger. Pat.* 314,803, 30.1.18.

THE lower portion of the oven is designed similar to the usual horizontal retort furnaces, while in the upper portion separate sources of heat, which can be controlled independently, are arranged for each chamber, and may lie in the longitudinal axis behind each other and side by side. Separate horizontal air, combustion, and gas collecting channels are provided between the upper and the lower portions in an intermediate part of the oven, which possesses inclined coke-discharging surfaces. Separate reserve heating gas chambers, which can also be controlled independently, are arranged between the chambers of the oven and the heating cells. Since each chamber is built in a special self-contained heating cell, it may be put into or out of work, according to requirements, without endangering the work of the whole oven. In consequence of the arrangement of the air, combustion, and gas collecting channels there is always a sufficient supply of heated air and a supply of heating gas for the heating of the chambers, so that a uniform temperature is maintained.—J. F. B.

Gas producers. J. West, Southport, and W. Wild, Blackpool. *Eng. Pat.* 137,647, 18.2.19. (Appl. 4010/19.)

THE fire-grate is vertical or inclined, and is formed wholly or partly of water tubes attached to a supply header at their lower end, and delivering into a header above the grate. The steam generated is delivered into the ash-pit, whence it is drawn into the furnace with the air supply. Cooling is thus effected without the necessity for a stream of water over the grate. Clunkering of the grate is required much less frequently, resulting in a more regular and constant production of gas and an economy of labour. The header above the grate, one side of which is heated by the furnace, contains water maintained at a constant level.—W. P.

Gas producers; Working of —. W. Beswick and N. E. Rambush, Stockton-on-Tees. *Eng. Pat.* 138,003, 24.5.19. (Appl. 13,123/19.)

WATER is circulated through parts of the producer which require to be cooled, and after being heated in this manner is brought into contact, in a separate chamber, with air which is to be supplied to the producer. The air is heated and more or less saturated with water vapour, and all the necessary

steam can be obtained from the water in circulation without the latter being heated to the boiling point. A circulating pump draws water from the bottom of a tower packed with coke or the like, and delivers it to the water jacket of the producer and to the water-cooled poker. The water is then returned to the top of the tower and is distributed over the packing, meeting the air which is to be supplied to the producer. A portion of the water may be withdrawn and replaced by fresh water. —W. P.

Gas for cutting and welding purposes. J. Harris, Lakewood, Ohio, Assignor to J. R. Rose, Pittsburgh, Pa. U.S. Pat. 1,329,400, 3.2.20. Appl., 3.8.18.

A mixture of hydrogen and carbon monoxide only is used, the carbon monoxide being not less than 5% or more than 20%, by volume, of the hydrogen. —W. P.

Gas; Manufacture of —. W. F. Rittman, Assignor to Synthetic Hydrocarbon Co., Pittsburgh, Pa. U.S. Pat. 1,329,853, 3.2.20. Appl., 23.2.16. Renewed 27.5.19.

Air and steam are forced through a body of incandescent carbonaceous material, the heated gases so produced being utilised to crack hydrocarbon fluids whilst out of direct contact with them. The heated gases are then mixed with the gases produced by the cracking process. —W. P.

Gas for balloons. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 303,966, 8.9.16.

Gas for filling balloons is treated with a small quantity, e.g. up to 3%, of ammonia or other volatile base such as zinc- or dimethylamine or piperidine, to prevent deterioration of the caoutchouc in the envelope. —J. H. L.

Blast-furnace and the like gases; Cleaning of —. J. E. Weyman, Newcastle-on-Tyne. Eng. Pat. 137,586, 10.1.19. (Appl. 781/19.)

A shaft running centrally through a drum carries arms threaded thereon loosely in pairs, each pair of arms being coupled by a framework filling more or less half the diameter of the drum. The filtering material or collecting surfaces are secured to this framework. The revolving arms carry the collecting surfaces at regular intervals up one side of the vessel and allow them to fall by gravity down the other side of the drum. The arms are lifted by means of slots in the drum casing, which revolves with the shaft. Spring arms or levers in the casing enable the arms to fall with a minimum of shock, though with sufficient to shake off the dust, which collects in a hopper at the bottom. The number and spacing of the arms are such that there is always one set between the inlet and outlet for the gas in the top half of the drum, and two or more between the gas inlet and outlet in the bottom half. —W. P.

By-products from coal; Process for recovery of —. Generator A.-G., Charlottenburg. Ger. Pat. 310,121, 10.12.16.

The coal is heated in a producer to which a distillation shaft is connected. The distillation gas, after condensation, is mixed with the producer gas, and the mixture washed with ammonia liquor and sulphurous acid obtained from recovered sulphur. The object is to obtain the gas tar and oils as direct products, and to recover ammonia and sulphur simultaneously in the form of ammonium sulphate and sulphur. By the action of the hydrogen sulphide in the gas on sulphur dioxide, in presence of ammonia, a solution of ammonium sulphate is obtained, which is used to absorb sulphur dioxide and so return it to the washer as an acid liquor.

The excess of acid liquor is evaporated to give ammonium sulphate, free sulphur, and sulphur dioxide. —H. J. H.

Paraffin; Process and apparatus for producing cakes of solid crude —. A. Szekely, Vienna. Eng. Pat. 131,293, 11.8.19. (Appl. 19,727/19.) Int. Conv., 30.5.18.

The crude solid paraffin residue ("gatsch") is melted and poured into a vessel with perforated walls partially immersed in water. The perforated walls above the water level are protected by a covering until the gatsch has solidified, after which the covering is removed and sweating is accomplished *in situ*. Sieve-like tubes, extending through the containing vessel and protected in a similar way during the setting of the gatsch, may also be provided. —A. E. D.

Hydrocarbons; Process of treating —. W. M. Cross, Kansas City, Mo., Assignor to Gasoline Products Co., Inc. U.S. Pat. 1,326,851, 30.12.19. Appl., 1.6.15.

GASOLINE is manufactured from heavier hydrocarbons such as residuum and the like by subjecting the vaporised hydrocarbons to a superheating treatment and preventing the deposition of carbon in the apparatus by injecting into the heated vapour a quantity of air less than is sufficient to cause complete combustion of the carbon in the apparatus. —J. F. B.

Oil-cracking stills; Furnace for —. F. E. Wellman, Assignor to Kansas Gasoline Co., Kansas City, Kans. U.S. Pat. 1,328,468, 20.1.20. Appl., 19.1.17.

A HEATING chamber is connected with the source of heat by a number of ducts, each provided with a damper. Each damper is adjustable, and all the dampers may be regulated by a common operation. —A. E. D.

Oil refining [cracking] apparatus. A. R. Jones, Independence, Kans. U.S. Pat. 1,328,522, 20.1.20. Appl., 9.10.16.

OIL is introduced through a feed pipe into a vertical pipe forming part of a tubular still, wherein cracking takes place. The vertical pipe is connected at its upper end with an approximately horizontal tube-system, and at the lower end with a catch-pot for carbon particles. —A. E. D.

Gasoline; Apparatus for recovery of — from casing-head gas. W. R. McGinnis, Assignor to Pilsbry-Becker Engineering and Supply Co., St. Louis, Mo. U.S. Pat. 1,328,680, 20.1.20. Appl., 14.5.17.

THE gas is compressed, cooled, and passed through a primary and a secondary separator, wherein free gas and gasoline are produced. —A. E. D.

Hydrocarbon; Apparatus for cracking —. T. E. Valey, Jamestown, N.Y. U.S. Pat. 1,329,450, 3.2.20. Appl., 19.4.17.

A CRACKING retort is provided with a nozzle which is connected by automatic non-return valves to the feed tank and to the primary condenser, wherein uncracked oil is collected. —A. E. D.

Carbon - removing means [in cracking hydrocarbons]. W. F. Rittman and C. B. Dutton, Pittsburgh, Pa. U.S. Pat. 1,329,852, 3.2.20. Appl., 5.2.17.

A rod extends into a tubular retort for cracking hydrocarbons practically the whole length. The rod is furnished with scrapers, and is given a reciprocating and oscillating motion. —W. P.

Hydrocarbons; Treatment [cracking] of —. W. F. Rittman, Pittsburgh, Pa. U.S. Pat. 1,330,008, 3.2.20. Appl., 5.2.17.

HIGH-BOILING oils in the vapour phase are exposed to cracking conditions, and the product is discharged into a receptacle, wherein, at low pressure, the desired low-boiling oil is vaporised and is subsequently condensed.—A. E. D.

Oil-bearing shale; Apparatus for distilling —. H. R. Straight, Adel, Iowa. U.S. Pat. 1,330,014, 3.2.20. Appl., 31.7.18.

AN internally-heated rotating retort is provided at the upper end with a hopper and at the lower end with a discharge valve. The retort is heated by a nozzle burner, which projects into the lower end of the chamber in the axis of rotation and which is fed with air and fuel.—A. E. D.

Petroleum spirit [benzine]; Process for breaking down high-boiling hydrocarbons into — and simultaneous conversion of unsaturated into saturated hydrocarbons. F. Bergius, Hanover, and A.-G. für Petroleum-Industrie, Nürnberg. Ger. Pat. 304,348, 6.5.13.

BENZINE is produced by heating high-boiling hydrocarbons in presence of hydrogen without catalysts, the hydrogen being under a pressure of at least 20 atm. The temperature necessary is about 450° C., but varies with the raw material. The products consist almost entirely of saturated compounds; they are colourless and have only a faint odour.

—J. H. L.

Lubricating oils; Process for purifying used —. W. v. Sperl, Hof. Ger. Pat. 314,175, 19.7.18.

FOUR parts of glycerin pitch and 1 part of water are boiled together to a syrupy consistence. One part of this mixture is boiled with 20 parts of the used lubricating oil and at least two parts of water. On standing clean oil separates.—H. J. H.

Coke-retorts; Apparatus for extracting coke from —. A. J. Nerrière, St. Brieux, France. Eng. Pat. 124,719, 24.2.19. (Appl. 4604/19.) Int. Conv., 28.3.18.

PATENTS.

Coal; Low temperature destructive distillation of —. J. Swinburne, London. Eng. Pat. 137,572, 4.1.19. (Appl. 261/19.)

COAL is distilled at 200°—350° C. by means of metallic electrical resistance heaters which sub-

divide a charge in a retort. The distillation is continued for upwards of 20 hours, and the oil produced is distilled substantially without cracking. The distillate resembles crude petroleum, and a rich gas is also produced.—W. F. F.

Acetone; Manufacture of — by the dry distillation of pyrolignite of lime and other acetates. L. Rappaport, Paris. Eng. Pat. 137,558, 19.11.18. (Appl. 18,984/18.)

PYROLIGNITE of lime containing about 75% of calcium acetate is distilled on a number of superposed trays of refractory material such as porcelain or sandstone, the lowest tray being supported on rollers of similar material. Each tray is provided with side openings for the escape of gas, and the furnace and supports are so constructed that the pyrolignite and the acetone formed do not come into contact with any metal. A higher yield of acetone is thus obtained.—W. F. F.

III.—TAR AND TAR PRODUCTS.

Liquites; Production of low temperature tar from — and its use as a source of viscous oils. W. Schneider. Ges. Abhandl. Kenntn. Kohle, 1919, 2, 80—127. Chem. Zentr., 1919, 90, IV., 935—937.

Low-temperature tars were prepared from two lignites, viz., a bituminous Central German lignite from the Riebeck Montan works, containing 20—30% of moisture and 15—16% of bitumen, and a non-bituminous Rhenish lignite (Union Briquettes) containing 15% of moisture and 3—4% of bitumen, by distilling the lignites, with superheated steam, at a maximum temperature of 450° C. in apparatus similar to that used by Fischer and Glund (see this J., 1919, 492 A). The tars differed physically from corresponding products from pit coal in their consistence (cp. Fischer and Glund, this J., 1919, 942 A) and setting point (37° and 33° C. for the two lignite tars). Their specific gravities at 50° C. were 0.883—0.890 and 0.955 respectively. They were subjected to fractional distillation in superheated steam, and their composition is shown in the accompanying table:—

Low-temperature tar from 100 kilos. of lignite (dry substance).	Bituminous lignite, 24 kilos. of tar (16% creosote)	Non-bituminous lignite, 7.6 kilos. of tar (36-38% creosote)
Viscous oils (freed from phenols) ..	17.2%	14.8%
Viscosity at 20° C., ° Engler ..	13.5	18.0
" " 50° C. ..	2.9	3.6
Comprising fractions:—		
(a) of high viscosity	1.73% (V ²⁰ = 67° E.)	2.8% (V ²⁰ = 7.4° E.)
(b) of medium	13.01% (V ²⁰ = 11.4° E.)	8.9% (V ²⁰ = 8.5° E.)
(c) of low	2.47% (V ²⁰ = 5.4° E.)	3.1% (V ²⁰ = 7.5° E.)
Hard and soft paraffins (montan wax, etc.)	29.4%	13.0%
Non-viscous oils	28.9%	26.2%
Acid fraction	10.5%	24.7%
Resin	2.2%	2.3%
Pitch	3.2%	8.5%

The viscous oils in low-temperature tar from lignite are not present in the original lignite, for extraction of the latter yields only solid bitumen. In pit coal, on the other hand, viscous oils are present before distillation and pass over undecomposed into the low temperature tar.—J. H. L.

Lignite; A technically produced low-temperature tar from —. W. Schneider and H. Tropsch. Ges. Abhandl. Kenntn. Kohle, 1919, 2, 128—132. Chem. Zentr., 1919, 90, IV., 937.

A TAR from a Central German lignite, obtained in

a producer with separate ducts for the distillation gases and tar vapours on the one hand and the producer gas on the other (*cp.* Fischer and Glud, this J., 1919, 492 A), contained only 3.7% of water, and less than 0.1% of matter insoluble in hot benzene. Subjected to fractional distillation with superheated steam it gave similar results to those obtained with low-temperature tars from lignite (see preceding abstract); the yield of viscous oils possessing lubricating characters was about 18%.

—J. H. L.

Lignites; Behaviour of low-temperature tar from bituminous and non-bituminous — when distilled under ordinary pressure. W. Schneider. Ges. Abhandl. Kenntn. der Kohle, 1919, 2, 133—144. Chem. Zentr., 1919, 90, IV., 937.

Low-temperature tar from a Central German bituminous lignite, having a setting point of 38° C., was distilled at the ordinary pressure under different conditions, *viz.*, from a retort in which the vapours escaped rapidly from the heated space; rapidly from an iron still in which the escaping vapours would be more exposed to heat than in the preceding case; and very slowly from the same still. The setting points of the distillates in the three cases were 24°—25°, 15°, and 0° C. respectively. Substantially similar results were obtained with a low-temperature tar from Rhenish lignite. The breakdown of high-boiling constituents into lower-boiling products could probably be carried even further, but there is a possibility that with very slow distillation condensation of unsaturated compounds to high-molecular substances might also occur.—J. H. L.

Lignite tar oils; Production of viscous oils from non-viscous — by heating in an autoclave. W. Schneider. Ges. Abhandl. Kenntn. der Kohle, 1919, 2, 145—150. Chem. Zentr., 1919, 90, IV., 940.

The high-boiling fractions (above 250° C.) obtained by a single distillation of low-temperature lignite tar can be rendered more viscous by heating for several hours at 300° C. in an autoclave, and their bromine absorption value is diminished at the same time. The thickened oil still contains unsaturated compounds even after heating for 34 hours. The change is due not to oxidation processes, but probably to polymerisation.—J. H. L.

Coal-tar and its constituents; Thickening of low-temperature —. F. Fischer, W. Glud, and P. K. Breuer. Ges. Abhandl. Kenntn. Kohle, 1919, 2, 222—235. Chem. Zentr., 1919, 90, IV., 934—935. (See also this J., 1919, 492 A, 942 A.)

Low-temperature tar and various fractions thereof, *e.g.*, the fractions boiling below and above 300° C., the phenolic constituents, and the tar deprived of phenolic substances, were heated under pressure in contact with "steel wool" in an autoclave at 320° C. for two successive periods of 3 days each. After this treatment the tar itself, and the hydrocarbons contained in it, showed a higher viscosity and density and a higher setting point than before. The phenolic constituents thickened more rapidly and to a greater extent than the hydrocarbons, giving products resembling pitch or asphalt. It is possible to transform the hydrocarbons of low-temperature tar into viscous products having the characters of true lubricating oils. Where phenols are also present the asphalt-like substances formed remain dissolved in the oils, but in the event of this condensation of the phenolic constituents being incomplete there would remain a possibility of further thickening taking place if the products were employed as lubricants at high temperatures. To produce heat-stable lubricants it would therefore appear advisable to remove the phenols in spite of the highly viscous products to which they give rise.—J. H. L.

Light petroleum and paraffin from coal; Production of —. Low-temperature tar. F. Fischer and W. Glud. Ges. Abhandl. Kenntn. Kohle, 1919, 2, 295—342. Chem. Zentr., 1919, 90, IV., 881—882. (See this J., 1919, 561 A.)

The light fraction of the tar oil from Minden coal can be obtained almost without attendant evolution of gas by distilling the coal at 240°—260° C. It is a clear green fluorescent oil of sp. gr. 0.763 at 20° C., and bromine-absorption value 4.4, and the yield is 0.35% on the coal. The loss on acid and alkali washing is extremely small. 65 c.c. of the product gave 20 c.c. of colourless spirit at 40°—100° C., sp. gr. 0.700, bromine value 2.5, and 36 c.c. of a fraction 100°—190° C., sp. gr. 0.783, and bromine value 6.8. It consists of paraffins mixed with naphthenes and compounds poorer in hydrogen. The small bromine values show that the products differ from those of low-temperature carbonisation carried to completion. As the Minden coal belongs to one of the newer formations, the existence of these liquid hydrocarbons is characteristic of the earlier stages of coal formation. The oil here described resembles closely another which had exuded from a coal seam. The essential difference between the low-temperature tars from coal and from lignite is that the former are liquid and the latter semi-solid. Coal contains liquid paraffins ready formed, while by extraction only solid products are obtained from lignite, and these appear also in its low-temperature tar. The low-temperature tars from gas coal and Saxon lignite on redistillation show a progressive fall in viscosity and setting point. In the practical recovery of such tars from gas producers it must therefore be possible to prepare tar of any desired viscosity and setting point. By working at temperatures below 600° C. and condensing all constituents liquid at the ordinary temperature, the tars which are least decomposed are those with the highest setting point. In these tars no great proportion of pre-formed lubricating oils is present, but transformation products, the result of heating in presence or absence of catalysts, have the character of lubricating oils. Jones (this J., 1917, 3) states that naphthalene appears in tars only above 750° C., so that its presence in tar is proof that the latter is not a true low-temperature product.—H. J. H.

Lamp oil fraction of low-temperature coal tar; Liquid paraffins of —. F. Fischer and W. Glud. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 39—45. Chem. Zentr., 1919, 90, IV., 882—883.

The fraction 200°—300° C. of a low-temperature tar from a gas coal (Lohberg) was treated with acetone to remove acid and basic components and cooled to -50° to -70° C., whereby a mixture of paraffins was separated which, at ordinary temperature, was a liquid, light pink in colour, with a blue fluorescence. The product was still impure and showed greater optical activity than the original oil. Further purification with concentrated and fuming sulphuric acid gave a colourless oil boiling from 150° to 336° C., which was apparently composed of paraffins in the range $C_{10}H_{22}$ to $C_{15}H_{32}$. The yield was at least 7.7% of the fraction 200°—300° C., and 1 to 1.5% of the original tar. The fraction 200°—300° C. of a low-temperature tar produced on the large scale, purified by concentrated and fuming sulphuric acid, gave 9.4% of liquid paraffins (1—1.5% on the original tar).—H. J. H.

Fuel oil and lamp oil (solar oil) from coal; Production of —. W. Glud. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 46—65. Chem. Zentr., 1919, 90, IV., 883.

The fuel and lamp oils obtainable from coal were investigated by distilling up to 300° C. the low-

temperature tar prepared from a gas coal (Lohberg), lignite tar from Riebeck'sche Montanwerke, and an ordinary gas tar. The phenols were removed, and after a double washing the residue was distilled and collected in fractions. Lamp oils of the range 150° – 310° C. were obtained in yields as follows:—Low-temperature tar, 18.8%; lignite tar, 30.2%; gas tar, 16.2%. The yields of crude products up to 300° C. were 33.9%, 47%, and 25% respectively. Corresponding fractions of the low-temperature tar and the lignite tar seemed to be identical, especially the solar oil fractions, which agreed in colour, specific gravity, ultimate analysis, calorific value, viscosity, etc. The solar oil fraction of the coal tar, with sulphur content 0.17%, seems to be the purest fraction and probably a mixture of paraffins, naphthenes, olefines, and higher aromatic hydrocarbons. The oils from gas tar were very different in composition, calorific value, and specific gravity. The solar oil fraction of low-temperature tar is distinguished by a small content of unsaturated compounds.—H. J. H.

Low temperature tar from lignite; Characteristic difference between — and other tars. F. Fischer and W. Schneider. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 200–212. Chem. Zentr., 1919, 90, IV., 883–884.

Low temperature lignite tar does not differ greatly in composition from the product obtained in the normal process, whereas low-temperature coal tar differs materially from gas tar. The differences with the lignite tars are quantitative rather than qualitative. It is not yet possible to lay down general characteristics of the tars from different lignites. Contrary to the experience with coal tars (this J., 1919, 941 A) the specific gravity of the tar after removal of phenols is not characteristic; the same is true of the residue on distillation to 300° C. A rapid test may be made as follows:—50 grms. of tar is dissolved in 100 c.c. of hot benzene, filtered hot, and washed with hot benzene. The benzene is distilled off and 20 grms. of the residue is stirred with 20 c.c. of light petroleum spirit (b. pt. 35° – 65° C.), filtered through a tared filter, washed with 20 c.c. of the same solvent, dried at 100° C., and weighed. Low-temperature tars from various lignites gave more than 30% of product insoluble in petroleum spirit. Other lignite tars gave less than 10%. The presence of naphthalene in a lignite tar shows that it is not a low-temperature product. Lignite tars are distinguished from coal tars by their consistency (Fischer and Gluud, preceding) and methoxyl content (Fischer and Tropsch, this J., 1919, 523 A).—H. J. H.

Nitro-compounds; Reduction of aromatic — by stannous chloride and by titanous chloride, and their volumetric estimation. D. Florentin and H. Vandenberghé. Bull. Soc. Chim., 1920, 27, 158–166.

WHILST the method described by Druce (this J., 1919, 247 A), using stannous chloride as the reducing agent, gives satisfactory results with most aromatic nitro-compounds, the authors find that with the three mononitrotoluenes, in particular *o*-nitrotoluene, the results obtained are too low. They recommend the use of titanous chloride in place of stannous chloride, the excess titanous chloride being titrated into a known volume of a standard ferric salt solution, using ammonium thiocyanate as an indicator. The results are accurate with all the nitro-compounds examined, except *o*-nitrotoluene, which gives results 3% too low.

IV.—COLOURING MATTERS AND DYES.

2-Nitro-4-cyanobenzaldehyde and 6,6'-dicyanoindigo. S. Reich and E. Lenz. Helv. Chim. Acta, 1920, 3, 144–157.

2-NITRO-*p*-TOLUNITRILE, colourless shining needles, m.pt. 107° C., is prepared from 2-nitro-*p*-toluidine by a modification of the method of Niementowski and Noyes, and is converted by *p*-nitrosomethyl-aniline in alcoholic solution in the presence of sodium carbonate into *p*-dimethylaminophenyl-2-nitro-4-cyanophenylazomethine,

$N(CH_3)_2 \cdot C_6H_4 \cdot N : CH \cdot C_6H_3(CN)(NO_2)$, almost black needles, m. pt. 182.5° – 183° C. (decomp.), which is hydrolysed by hydrochloric acid, yielding 2-nitro-4-cyanobenzaldehyde, red needles, m.pt. 110° C. When the aldehyde is dissolved in acetone and treated with dilute sodium hydroxide solution, 6,6'-dicyanoindigo is deposited as a bluish-violet powder with metallic lustre; when heated it does not sublime but decomposes with evolution of reddish-violet vapours. After reduction with sodium hydrosulphite it dyes wool and cotton from an alkaline bath in reddish-purple shades which become blue with a tinge of violet on exposure to air, oxidation proceeding more slowly than with indigo. The shades are fast to light and milling. (See further J. Chem. Soc., 1920, i., 255.)—H. W.

Aniline; Oxidation of —. Amine oxidation. I. S. Goldschmidt. Ber., 1920, 53, [B], 28–44.

THE author holds the view that there are two initial products of the oxidation of aniline, according to the conditions. Agents which readily yield atomic oxygen, such as Caro's acid or hydrogen peroxide, produce aniline oxide, which changes into phenylhydroxylamine and then gives nitrosobenzene, nitrobenzene, azobenzene, and azoxybenzene. Aniline oxide or phenylhydroxylamine cannot account, however, for the production of benzoquinonephenyldi-imine, $C_6H_5 \cdot N : C_6H_4 : NH$, and subsequently of Emeraldine, Aniline Black, etc. Under conditions which lead to these products the initial stage is represented by the hypothetical radicle, $C_6H_5 \cdot N :$. This may, for example, polymerise to azobenzene or benzoquinonephenyldi-imine, the first demonstrable products of the oxidation of aniline by alkaline permanganate or bleaching powder, or polymerise to Emeraldine. The assumption is based on the fact that azo-compounds and quinonearyldi-imines can be isolated when aniline, and especially xylidine, eunidine, or aminodurene are oxidised by lead peroxide, and is considerably strengthened by the fact that mixed azo-compounds and mixed quinonearyldi-imines are produced when two amines are oxidised together. (See further, J. Chem. Soc., 1920, i., 226.)

—J. C. W.

Quinone-imide dyes. XII. Absorption spectra of some cyano-acridine and cyanopyrroline dyes. F. Kehrman and M. Sandoz. Ber., 1920, 53, [B], 63–66. (Compare this J., 1918, 364 A.)

ABSORPTION curves for three sets of comparable dyes are reproduced, showing that the replacement of the trivalent nitrogen atom in safranines and azoxines by the group $C \equiv N$, has practically no effect on the colour. (See further, J. Chem. Soc., 1920, ii., 142.)—J. C. W.

Coloured substances; Determination of the constitution of — from their absorption spectra. II. F. Kehrman and M. Sandoz. Helv. Chim. Acta, 1920, 3, 104–114.

ALCOHOLIC solutions of phenazine and aminophenazine are almost colourless and orange respectively, whilst similar solutions of sym. and 2,3-diaminophenazine are pale yellow and very

light yellow; this is in accordance with the author's theory that the introduction of an amino group in the *para*-position to the nitrogen of quinonimines or in the same position with respect to the methane carbon atom of triphenylmethane has a hypsochromic or bathochromic influence which depends on the basicity of the group into which it enters. The introduction of the first amino group into phenazine considerably increases its basicity, but this is not the case with the second group. Phenylated derivatives of phenazine are slightly more reddish than the corresponding non-phenylated compounds, but are chiefly noticeable for the increased intensity of colour effected by introduction of the phenyl-group. In general, the absorption curves of the bases do not present any striking anomalies, and the authors therefore attribute to them the ortho-quinonoid structure of phenazine itself. Mono- and di-aminophenazines when dissolved in fuming sulphuric acid have very similar absorption spectra, and appear to have the orthoquinonoid structure. When, however, the solutions are gradually diluted with concentrated sulphuric acid, the blood-red colour suddenly changes to green, probably owing to hydrolysis. The authors ascribe the para-quinonoid constitution to the di-acid and mono-acid salts as well as to the green tri-acid compounds. The ultra-violet spectra of the bases and of the mono-acid salts have been examined. With the former, an absorption band is invariably observed which becomes progressively displaced towards the visible violet as the chromogen becomes more highly substituted. The location of the anilino-groups, which has such a marked influence on the position of the bands in the visible spectrum, appears to have no effect on the position of the band in the ultra-violet. Isomeric substances with equal molecular weights appear to give superposable spectra in the ultra-violet.

—H. W.

Ortho-quinones; Action of o-aminothiophenol on —. I. Naphtho-6-phenothiazine. K. Stahr-foss. *Helv. Chim. Acta*, 1920, 3, 134–138.

o-AMINOTHIOPHENOL hydrochloride reacts with 4-amino-1,2-naphthoquinone in boiling 80% acetic acid solution with the formation of naphtho-6-phenothiazine hydrochloride, a chocolate-brown powder which is stable in air and readily soluble in water. The free base is an unstable yellow substance, the constitution of which follows from the conversion of the hydrochloride by concentrated sulphuric acid into a naphthophenazthione identical with that formed from *o*-aminothiophenol and 4-hydroxynaphthoquinone.—H. W.

Rhodanines. C. Grünacher. *Helv. Chim. Acta*, 1920, 3, 152–163.

IN the oxidation of rhodanine to Nencki's Rhodanine Red with ferric chloride the imino-hydrogen atom of rhodanine is not affected, since *N*-substituted rhodanines, such as *N*-phenylrhodanine, also yield red dyes under suitable conditions. On the other hand, benzylidenerhodanine is not changed by ferric chloride, so that the presence of a free methylene-group appears essential to the production of a dye. Alkylidenerhodanines react with aniline and phenylhydrazine to yield the corresponding anilides and phenylhydrazones, the sulphur of the thio-keto group being removed as hydrogen sulphide. Since aniline is comparatively readily removed from these anilides, they can be employed for condensing the rhodanine molecule with compounds containing a reactive methylene group; in this manner, benzylidenerhodanine-anilide can be condensed with a second molecule of rhodanine to yield *α*-benzylidene-*α*-rhodanal-rhodanine. Reaction with aniline or phenylhydrazine proceeds in a totally different manner with

rhodanines, such as *N*-phenylrhodanine, which contain the free methylene group; in this case, the sulphur of the thio-keto group remains unaffected and complete fission of the rhodanine ring occurs with the formation of thioureas or thiosemicarbazides, reaction occurring so readily that the process is conveniently used for the preparation of the latter class of substances. (See further *J. Chem. Soc.*, 1920, i., 252.)—H. W.

Phlorouacetophenone. K. B. Sen and P. C. Ghosh. *Chem. Soc. Trans.*, 1920, 117, 61–63.

ON heating phloroglucinol with glacial acetic acid and zinc chloride, a yellow crystalline compound is obtained, which is a pyran derivative produced by the combination of two molecules of the initially formed phlorouacetophenone. On boiling this 5,7-dihydroxy-2-*o*-*p*-trihydroxyphenyl-4-methylene-1,4-benzopyran with 10% sodium hydroxide the heterocyclic ring is broken and phlorouacetophenone regenerated. It forms white crystals, m. pt. 284°–285° C., and gives a phenylhydrazone which decomposes at 237°–240° C.—G. F. M.

Dyes and yeast cells. Von Euler and Florell. *See* XVIII.

Colour lakes. Bremner. *See* XXIII.

PATENTS.

Pyrazole-anthrone Yellow; Derivatives of —. F. Singer and A. Holl, Offenbach, Germany, Assignors to Chemical Foundation, Inc. U. S. Pat. 1,329,435, 3.2.20. Appl., 23.9.15.

See Eng. Pat. 14,103 of 1915; this J., 1916, 1101.

Sulphur dye; Blue — and process of manufacturing same. L. A. F. Haas, Assignor to Soc. Anon. l'Air Liquide, Paris. U.S. Pat. 1,329,898, 3.2.20. Appl., 5.8.18.

See Eng. Pat. 118,103 of 1918; this J., 1919, 676A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose; Heating — with benzene under pressure. F. Fischer and W. Schneider. *Ges. Abhandl. Kenntn. Kohle*, 1919, 3, 287–300. *Chem. Zentr.*, 1919, 90, IV., 879. (See also Fischer and Niggemann, this J., 1919, 491A; Fischer and Kleinstück, p. 218A.)

CELLULOSE heated with benzene under pressure at 250°–260° C. is gradually decomposed, with the formation of water and products dissolved in the benzene, but scarcely any gas products. The decomposition products are about 6% greater in amount than the normal yield of tar on destructive distillation. They are dark-brown viscous liquids, and about 90% is soluble in alkalis. On acidification the solution deposits brown flakes (47.5%). The bulk of the extract is insoluble in light petroleum spirit, soluble in cold chloroform, and almost completely soluble in cold alcohol. The presence of water accelerates the process of extraction and improves the yield. Thus a double extraction of dry cellulose by dry benzene gave 2% of products, of air-dry cellulose (5.4% H₂O) 6.4%, and in presence of water 12%. By protracted heating of air-dry cellulose with benzene under pressure a yield of 12% is also attainable.—H. J. H.

Paper testing; Report on —. F. C. Clark. *Paper*, 1919, 25, 693–699, 739–743, 777–780, 829–831, 877–879.

THIS is the report of the Committee on Paper Testing presented to the Technical Association of the

Palp and Paper Industry (U.S.A.). The tests are considered under the heads of microscopical, physical, and chemical, and selected methods and apparatus are described. Microscopical examination relates principally to the fibres, their nature, proportions, and condition of beating; it comprises also the identification of the starches and specks in the paper. Physical tests comprise the following: Area, weight, bursting strength per unit area, thickness, bulk or thickness of a number of sheets, folding endurance, tensile strength, elongation at rupture, absorption, opacity, gloss or glaze, translucency, degree of sizing, retention of loading, breaking length. Chemical tests include percentage of ash, identification of loading, percentage of paraffin, sizing material, coating material, presence of acids, free chlorine, etc. A chart is given illustrating the relationships of the various tests to each other in the determination of the quality of the paper.—J. F. B.

Sulphite spirit manufacture; Influence of the design of the digester fittings on the quantity of waste liquor for —. A. D. J. Kuhn. *Woch. f. Papierfab.*, 1919, 50, 2317—2319, 2388—2391. *Chem. Zentr.*, 1919, 90, IV., 1016.

IN sulphite pulp mills which work up their waste liquors for the manufacture of spirit it is very important to have the correct proportion of fresh liquor to the quantity of wood and to employ a liquor which is rich in free sulphur dioxide. The ratio of liquor to wood depends upon the method of digestion, the species and the moisture-content of the wood, so that the quantity of waste liquor may show variations between 5 and 10 cub. m. per ton of cellulose. The digestion itself proceeds most favourably when the proportion of free sulphur dioxide is at least 70—80% of the total. A liquor rich in free acid increases the yield of sugar and alcohol. The digestion must be stopped when the concentration of sugar in the liquor has reached its maximum, because the sugar which has been formed then undergoes a gradual decomposition. Moreover, the use of a liquor of high concentration effects an economy of sulphur and steam and a higher efficiency in the digester with uniform results in the product. In order to obtain the maximum quantity of waste liquor, the digester must be drained under pressure. By blowing off under a pressure of 4—5 atm. the cellulose retains only 4 cub. m. of liquor per ton, whereas when blown off under 2—3 atm. the pulp retains 5.25 cub. m. per ton. It is also advantageous to introduce hot water on to the pulp under pressure, because in this way the water displaces the spent liquor, whereas the introduction of water without pressure merely results in the dilution of the spent liquor. The spent liquor coming from the digester under high pressure should be conducted to a pressure relief vat, where a powerful evolution of sulphur dioxide takes place, and this gas may be recovered for use in the preparation of fresh liquor.—J. F. B.

Extraction of vegetable tissues with benzene. Fischer and Kleinstück. *See* II A.

Sulphite-cellulose in tanning extracts. Knowles. *See* XV.

PATENTS.

Impregnating yarns and fabrics of paper; Process for —. O. Ruff and P. Praetorius, Breslau. Ger. Pat. 303,926, 21.3.17.

AQUEOUS solutions of phenols with formaldehyde and alkali are heated together, but not long enough to permit of the separation of insoluble products, and are then used for the impregnation of paper materials. By heating the latter further insoluble condensation products are formed. To add to the strength of the fabrics a further treatment with formaldehyde may be used.—H. J. H.

Fibres suitable for spinning from rushes ("Binsen"); Production of —. Deutsche Typha-Verwertungs-Ges.m.b.H., Charlottenburg. Ger. Pat. 308,565, 20.2.18.

THE bundle of fibres composing the rushes is disintegrated by a preliminary treatment with hot water, steam, either under pressure or not, or extremely dilute alkali, and then by the action of a strongly corrosive reagent, such as dilute caustic soda, which removes the tissues binding together the threads. The useful fibres are found in the outer parts of the plant.—H. J. H.

Textile fibres; Production of —. V. Wilke and L. Schorsch, Bielitz. Ger. Pat. 314,176, 6.1.18. Int. Conv., 25.1.17.

FOR the preparation of textile fibres from all kinds of vegetable matter—leaves, stalks, tendrils, etc., from the silk cocoon, and from spinners' waste—the raw material is treated with soap-makers' spent lye, with or without the admixture of alkali and/or other substances. The soap liquor dissolves or converts into soluble form the pectins (incrusting substances) without attacking the fibres. The dissolved matter must be removed by washing in a current of water or by boiling in water, followed sometimes by washing in dilute acid to soften the material.—H. J. H.

Paper; Process for producing sewing or basting thread from —. Vohwinkler Papier- u. Salicyl-Pergamentpapier-Industrie, Vohwinkel. Ger. Pat. 314,490, 16.4.18.

PAPER threads of suitable strength are impregnated with a mixture consisting of paraffin or stearine, linseed oil, mineral oil, and varnish, and afterwards drawn between corks to remove the excess.—J. H. L.

Yarn, ribbons, fibres, webbing, etc.; Machine for treating articles such as — with liquids. A. Schmidt, Charlottenburg. Ger. Pat. 314,721, 2.3.18.

THE material is drawn horizontally in series through the liquid contained in a tier of shallow boxes one above the other. The liquid is fed evenly into the top box and gravitates downwards from box to box after traversing each from end to end. The material may pass in the same direction as, or in the opposite direction to, the current of liquid. The arrangement has the advantage over deep baths through which the material is conducted vertically that only a small quantity of liquid is required, and that the heat losses are low when a hot liquid is used.—H. J. H.

Sulphite fibre; Process of manufacturing — and recovering sulphur dioxide. J. P. V. Fagan and H. G. Spear (Assignors to Brown Co.) and R. B. Wolf, Berlin, N.H. U.S. Pat. 1,327,666, 13.1.20. Appl., 30.4.18.

DURING the last portion of the cooking operation the gases and vapours which are usually blown with the digester contents into the blow pit are blown into a condenser from the top of the digester and the sulphur dioxide recovered.—L. L. L.

Straw, hay, wood, etc.; Treatment of — by boiling or steaming with reagents. E. Hauss, Osnabrück. Ger. Pat. 298,863, 1.1.16.

THE material is treated in a boiler with a suitable reagent in presence of air, oxygen, or a substance yielding oxygen, e.g. hydrogen peroxide. Economy of time and reagent are thereby attained.—H. J. H.

Cellulose from slightly lignified plants; Manufacture of —. M. Lüders, Magdeburg. Ger. Pat. 301,716, 30.8.16.

MATERIALS such as jute, manila, bullrush, typha,

flax straw and flax waste, hemp straw and hemp waste, nettle straw, etc., are digested in a closed vessel under pressure with a weakly acid magnesium sulphite solution, which, according to the degree of lignification of the material, may contain up to 90% of its sulphur dioxide in the combined state.—J. F. B.

Cellulose; Process for the production of — from moss or peat by heating with dilute acids. C. F. Hildebrandt, Hamburg. Ger. Pat. 311,712, 22.12.17.

Moss or peat is digested with dilute acids at a temperature below 100° C. and under atmospheric pressure, without subsequent treatment with alkaline liquors, and the process is arrested before saccharification commences. After washing, or partial or complete neutralisation, the cellulose obtained may be employed as fodder or for the production of paper, nitrocellulose, etc.—J. H. L.

Coating material [from viscose]. J. H. Young, Assignor to Aspromet Co., Pittsburgh, Pa. U.S. Pat. 1,327,933, 13.1.20. Appl., 11.9.18.

Viscosz is mixed with a soluble soapy material, the mixture having a lower surface tension than the viscose alone and being capable of spreading evenly over and firmly adhering to a sticky surface.

—B. V. S.

Viscose solutions; Preparation of improved, more stable —. R. Linkmeyer, Barby, and H. Hoyermann, Hanover. Ger. Pat. 312,392, 17.11.17.

Viscose solutions are treated with substances which contain amide or imide groups or are capable of forming such groups. Suitable substances are: Urea, derivatives of urea, cyanamide, dicyanodiamide, guanidine and its derivatives, acid amides, urethane, cyanates, thiourea, mustard oils, and condensation products of the above substances with aldoses. The viscose solutions are thereby rendered more stable and remain suitable for spinning for several weeks; the threads are characterised by good strength, but are sensitive to the action of water when they have been precipitated in a coagulating bath containing formaldehyde.—J. F. B.

Films and celluloid plates; Production of —. Deutsche Celluloid-Fabrik, Eilenburg. Ger. Pat. 314,119, 31.1.17.

NITROCELLULOSE, either dry or dehydrated by alcohol, is dissolved with a gelatinising agent in alcohol and rolled out to plates of small thickness, which are dried and treated with anhydrous solvents. Exclusion of every trace of water adds to mechanical strength.—H. J. H.

Paper, papier-mâché, and the like; Preparation of pulp or fibrous material for the manufacture of —. L. H. Skinner, London. Eng. Pat. 137,105, 30.12.18. (Appl. 21,790/18.)

FRONES of a silky nature are obtained from the tree mallow plant or from the tree mallow grafted or budded on to the stalk of a Jerusalem artichoke or sunflower. The stems are collected in the late autumn, preferably after frost; they are chopped, boiled with water for about eight hours, and reduced to pulp in a beating engine.—J. F. B.

Paper-making [from waste paper]. C. T. Crocker, Fitchburg, Mass. U.S. Pat. 1,326,849, 30.12.19. Appl., 21.10.18.

A CONTINUOUS stream of pieces of waste paper is subjected to the action of a hot alkaline solution by causing each oncoming piece of paper, as nearly separate as possible, to be submerged in and moved through the solution, to facilitate the exposure of its surfaces to the action of the solution for the purpose of removing or neutralising the ink or

other material fixed to the surface. The pieces of paper are then removed from the solution and freed from the major portion of the adherent liquid, exposed to the air to cool, and treated in a washing machine.—J. F. B.

Paper; Sizing of —. O. Ruff, Breslau. Ger. Pat. 307,691, 19.1.18.

THE paper pulp is first made neutral or alkaline, then treated with an alkaline solution of condensation products of phenols and formaldehyde, and finally acidified. The finished paper is heated for about an hour at 120° C. in a drying chamber, or passed slowly over the rollers of a drying machine heated to 120°—140° C.—J. H. L.

Paper or board; Process and machine for the manufacture of easily folded —. J. M. Voith, Heidenheim. Ger. Pat. 314,611, 25.7.18.

WEBS of paper pulp made on a flat or cylindrical machine with an uninterrupted wire surface are combined at the wet press with webs made on a machine, the wire of which is partly covered.

—J. F. B.

Cleaning material; Production of — from the waste of the paper industry. Reis and Co., Friedrichsfeld. Ger. Pat. 306,461, 18.9.17. Addition to 303,302 (this J., 1920, 15 a).

THE alkali in the liquor is partly replaced by salt, and the treatment is effected in the cold; e.g., the waste is treated with a liquor containing 10 parts of caustic soda to 60 parts of salt for three to four hours.—H. J. H.

Wood pulp; Process and apparatus for reclaiming waste products in the manufacture of —. H. K. Moore and J. T. Quinn, Berlin, N.H., Assignors to Brown Co., Portland, Me. U.S. Pat. 1,326,414, 30.12.19. Appl., 13.2.18.

WASTE liquor is "exploded" (atomised) in a furnace and the disintegrated particles are subjected to heat to cause the evaporation of the liquid content and the combustion of the combustible matter.

—J. F. B.

Cellulose and like substances; Apparatus for bleaching —. A. D. Berglind, Klosterpossen, Norway. U.S. Pat. 1,329,824, 3.2.20. Appl., 3.5.18. SEE Eng. Pat. 114,456 of 1917; this J., 1918, 296 a.

Volatile solvents. Ger. Pat. 303,396. See I.

Resinous substances. Ger. Pat. 314,118. See XIII.

Material treated with cellulose derivatives. U.S. Pat. 1,327,197. See XV.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Dyeing mixtures of wool and staple fibre. G. Rudolph. Färber-Zeit., 1919, 30, 285—286.

THE staple fibre is dyed, at as low a temperature as possible (50°—60° C.), with direct cotton colours, which can be diazotised and developed. By this method shades fast to bleeding, washing, and milling are produced. The wool is then dyed by neutral wool dyestuffs. For general fastness the use of vat colours is recommended. With many vat colours a level tone is obtained directly; with others the wool is dyed a paler shade, and in such cases the shade is deepened by means of fast acid colours. For the production of shades fast to light the wool is dyed by means of neutral wool colours and the staple fibre by direct cotton dyes which can be after-coppered.—L. L. L.

Printing; Discharge — on staple fibre union material. O. Gaumnitz. *Färber-Zeit.*, 1919, 30, 286—287.

STAPLE fibre is reduced in strength considerably in a damp condition. To overcome this defect union yarns consisting of 25—75% of staple fibre and 75—25% of wool are produced. The raw material woven from such yarn is singed or cropped and then crabbed. It is then dyed with dischargeable colours and printed with basic dyes along with a discharge for the production of fancy goods. The colour from the staple fibre is more readily discharged than that from the wool, leaving web-like effects.—L. L. L.

Colour lakes. Brenner. See XXIII.

PATENTS.

Bleaching and similarly treating textile fabrics and yarns in rope form; Machines for —. W. Morley, Bolton, and Bleachers' Assoc., Ltd., Manchester. Eng. Pat. 136,713, 20.2.19. (Appl. 4229/19.)

THE material in rope form is fed mechanically into kiers or cisterns, along with a stream of liquor, through a hollow trunk of metal or other suitable material. The trunk is hinged or pivoted to a metal box casting or the like and receives a reciprocating motion lengthwise of the kier or cistern, and also a transverse oscillating movement. For round vessels, when desirable, a variable speed and variable throw of stroke to the trunk may be imparted in order to fit the material to the vessel. The feeding of the material into the kier or cistern along with the liquor insures thorough impregnation before entering the vessel.—L. L. L.

Bleaching composition. R. B. Kadish and T. W. Buscher, Assignors to The Kadish Manufacturing Co., Chicago, Ill. U.S. Pat. 1,327,394, 6.1.20. Appl., 11.12.17.

THE composition is obtained by mixing a fluoride, a hydroxide, and an acid sulphate of an alkali metal while in a nearly dry state.—L. L. L.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,327,200, 6.1.20. Appl., 13.11.17.

THE machine comprises a receptacle provided with a series of fibre chambers, within each of which is a non-perforated core. The fibre to be treated is wound upon non-perforated hollow members which slide over the cores. Means are provided at each end of the fibre chambers for compressing the fibre and also means for forcing a liquid through the compressed fibre.—L. L. L.

Dyeing machine; Skein —. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,327,657, 13.1.20. Appl., 22.8.17.

A DYEING chamber is provided with a removable frame adapted to carry fibre skeins, with a series of foraminous pipes below the frame, and a removable top carrying a series of foraminous pipes. Means are also provided for removing liquid from the dyeing chamber below the frame and for forcing liquid through either series of pipes and through the dyeing chamber.—L. L. L.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats (A) 1,327,658, (B) 1,327,660, and (C) 1,327,662, 13.1.20. Appl., (A) 13.11.17, (B) 24.12.17, (C) 26.1.18.

(A) WITHIN the dye vessel is a series of cores, each carrying an extended arm supporting a series of annular members. The fibre to be dyed is wound upon hollow foraminous spindles, which slide upon the annular members. Means are provided for forcing liquid transversely through the spindles and

through the fibre and also for compressing the fibre upon the spindles. (B) The machine consists of a vessel containing a series of fibre chambers, each provided with a foraminous end and a foraminous plate, which slides within the chamber and compresses the fibre between the end and the plate. The fibre chambers are connected by a series of inwardly diverging tubes with liquid chambers, and means are provided for continuously passing liquid in opposite directions through the tubes, the foraminous members, and the fibre within the fibre chambers. (C) The machine comprises a series of fibre chambers, each provided with a foraminous spindle, upon which fibre is wound. Means are provided for forcing liquid in either direction through the series of spindles and fibre wound thereon.—L. L. L.

Fabric-treating device. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,327,659, 13.1.20. Appl., 20.12.17.

THE device consists of a series of fabric chambers into each of which is inserted a foraminous core upon which the fabric is wound. The wound fabric is encased by a foraminous cover. Means are provided for closing all the openings of the core except those adjacent to the fabric and for forcing the liquid through the fabric in either direction.—L. L. L.

Dyeing device. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,327,661, 13.1.20. Appl., 7.1.18.

THE device comprises a series of fabric chambers with non-perforated side walls, within each of which is a series of hollow foraminous fabric reels; the upper end of each fabric chamber and hollow reel may be closed. Liquid chambers are connected to the lower ends of the hollow reels and to the lower ends of the fabric chambers, and means are provided for passing liquid in opposite directions through the device and the fabric wound upon the reels.—L. L. L.

Fibre-treating machine. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,327,663, 13.1.20. Appl., 13.3.18.

THE machine consists of a receptacle provided with a series of removable hollow foraminous spindles upon which the fibre is wound. Means are provided for closing one end of the spindles, for compressing the fibre in the direction of the axes of the spindles and also at right angles to the axes, and for passing liquid in either direction from the receptacle to the interior of the spindles and through the fibre.—L. L. L.

Hosiery-dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,327,756, 13.1.20. Appl., 22.6.18.

THE two end plates of a dyeing receptacle are connected by a series of spaced bars revoluble within the receptacle, and a series of foraminous plates extends outwards from the bars and abuts upon the end plates, their outer extremities being connected by removable foraminous covers, which, together with the end plates, form a series of fabric chambers. Means are provided for revolving the fabric chambers and for forcing liquid through them, the chambers being maintained beneath the liquid during its passage therethrough.—L. L. L.

Woollen fabrics dyed fast to milling; Process for improving the wearing quality of —. L. Cassella und Co., Frankfurt. Ger. Pat. 303,223, 17.1.17.

THE dyed fabrics are treated with tannins or formaldehyde or both, or with tannins in combination with metallic salts. In comparing the effectiveness of these different methods of treatment the

treated fabrics may be exposed to light and weather for several months and then subjected to the biuret test. Those which have deteriorated most will give the strongest violet coloration.—J. H. L.

Dyeing yarns and fabrics of paper treated with phenol-formaldehyde condensation products; Process of —. O. Ruff, Breslau. Ger. Pat. 306,447, 1.9.17.

THE dyestuff is added to the liquid used for impregnating the material and fixed by subsequent heating. Dyestuffs suitable for this purpose are those which are fast and not precipitated in slightly alkaline baths—e.g., sulphur, basic, and substantive colours. As example is given the use of a condensation product of crude cresol, 8% caustic soda, and formaldehyde, and a solution of a sulphur colour in caustic soda and sodium sulphide.

—H. J. H.

Aniline Black; Process of producing —. A. Ehrenzweig, Hermsdorf, and M. van Delden und Co., Gronau. Ger. Pat. 314,660, 2.10.15.

ANILINE, a diamine, and chlorate are employed together with cyanogen or thiocyanogen compounds containing no iron, copper, or other heavy metals. It is thus possible to effect oxidation of the whole of the aniline or diamine and obtain great depth of colour without risk of weakening the fibre.

—J. H. L.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur dioxide; Solubility of — in sulphuric acid. F. D. Miles and J. Fenton. Chem. Soc. Trans., 1920, 117, 59—61.

THE solubility of sulphur dioxide in sulphuric acid diminishes fairly regularly with increasing concentration of the acid to a minimum value with 86% acid, after which a sudden and rapid increase in solubility accompanies further increase in the percentage strength of the acid. The solubility of the gas at 20° C. and normal pressure was determined over a series of concentrations from 55% acid upwards, and following are some of the results:—

Sulphuric acid, per cent.	Grms. SO ₂ dissolved in 100 grms. of acid.	Sulphuric acid, per cent.	Grms. SO ₂ dissolved in 100 grms. of acid.
55.1	5.13	88.1	2.90
68.9	4.16	92.8	3.21
80.2	3.12	95.5	3.60
85.8	2.80	98.5	4.03

—G. F. M.

Sulphurous acid; Oxidation of — by ferric salts. J. Meyer. Ber., 1920, 53, [n], 77—78.

A CRITICISM of Houben's recent method for estimating acids and ferrous and ferric salts in the same solution (this J., 1920, 85 A). (See further, J. Chem. Soc., 1920, ii., 173.)—J. C. W.

Iodides; Oxidation potentiometric titration of — in the presence of chlorides and bromides. I. M. Kolthoff. Rec. Trav. Chim., 1920, 39, 208—214.

USING the potentiometric method previously described (this J., 1919, 444 A) iodides may be estimated by titration with potassium bichromate or, preferably, potassium bromate or iodate, in the presence of hydrochloric acid. Chlorides do not interfere with the titration, and the presence of relatively large amounts of bromides does not vitiate the results.—W. G.

Ammonium silicate. III. R. Schwarz and R. Sonard. Ber., 1920, 53, [n], 1—17. (Compare this J., 1919, 498 A.)

AMMONIACAL solutions of dioxadisiloxane or monosilane, or of preparations of silicic acid from various sources, provided they have not been ignited, have higher conductivities than ammonia solutions, which indicates the formation of ammonium silicate. The increment, however, is dependent on the initial proportion of water in the material employed, and the results indicate that the dissolved silicic acid exists in three forms, of molecular weights in the ratio 1:2:3. (See further J. Chem. Soc., 1920, ii., 175.)—J. C. W.

Barium sulphide; Action of water on —. E. Terres and K. Brückner. Z. Elektrochem., 1920, 26, 1—24.

A DOUBLE compound Ba(SiH₃OH)₂·5H₂O is formed when barium sulphide is extracted with water at all temperatures up to 100° C. This compound is comparatively stable, and under no circumstances can barium hydroxide be separated from the solution by crystallisation. These results explain the failure of many processes put forward for the manufacture of barium hydroxide from barium sulphide. (See also J. Chem. Soc., Apr., 1920.)

—J. F. S.

Strontium sulphide; Action of water on —. E. Terres and K. Brückner. Z. Elektrochem., 1920, 26, 25—32.

STRONTIUM sulphide is converted into strontium hydroxide and strontium hydrosulphide by the action of water, and there is no formation of an intermediate hydroxy-hydrosulphide as in the case of barium (see preceding abstract). The solution obtained by treating strontium sulphide with boiling water, on cooling deposits pure strontium hydroxide. (See also J. Chem. Soc., Apr., 1920.)

—J. F. S.

Chromium chromate. M. Z. Jovitchitch. Helv. Chim. Acta, 1920, 3, 40—46.

WHEN a solution of chromium oxide in nitric acid is evaporated until excess of acid is removed, and the residue is dissolved in water and treated with ammonia, a dark-brown, almost black, product is obtained, having the composition CrO₃·Cr₂O₃·71H₂O. The substance loses 11H₂O when placed over sulphuric acid, 21H₂O at 105° C. and 61H₂O at 205° C. It loses chromium trioxide even on protracted washing with warm water. It may be used for the preparation of pure chromium hydroxide free from alkali by treating its solution in boiling concentrated hydrochloric acid with alcohol till reduction is complete and then precipitating with an excess of ammonia. Anhydrous chromium chromate is obtained as a porous, black mass by dissolving chromium oxide in nitric acid, evaporating the solution to dryness and cautiously heating the residue to 290° C. It is readily converted by ammonia, alkali carbonate or hydroxide, or by boiling water into chromate and chromium hydroxide.

—H. W.

Chromium hydroxide; Formula of —. M. Z. Jovitchitch. Helv. Chim. Acta, 1920, 3, 46—49.

THE formula Cr₃(OH)₈O₂·10H₂O or Cr₃(OH)₁₀O·9H₂O is assigned to chromium hydroxide on account of its solubility in ammonia and the preparation from such solutions of complex salts which invariably contain 10H₂O, and also because it absorbs carbon dioxide from the air with the formation of the carbonate CO₃Cr₂(OH)₂·8H₂O. (See also J. Chem. Soc., 1920, ii., 179.)—H. W.

Calcium hydride; Some reactions of —. S. Reich and H. O. Serpek. *Helv. Chim. Acta*, 1920, 3, 138–141.

CARBON monoxide is reduced by calcium hydride at a dull red heat with formation of hydrogen, methane, and formaldehyde. When a mixture of the hydride with sodium carbonate or bicarbonate is gently heated, formic acid is produced. Ammonia is formed in small amount when nitrogen is passed over calcium hydride at about 500° C., but the main reaction appears to consist in the formation of calcium nitride. Acetone reacts energetically with finely divided calcium hydride giving mesityl oxide and a cyclic substance, b. pt. 226°–236° C. Calcium hydride appears to act as a reducing agent only at very high temperatures, and its use in the hydrogenation of organic substances must be very limited, particularly as its action, when occurring, appears to lead preferably to condensation products. (See also *J. Chem. Soc.*, 1920, i., 249.)

—H. W.

Lead borates. H. V. Thompson. *Trans. Ceram. Soc.*, 1918–9, 18, 510–511.

ABEGG (*Handb. der anorg. Chem.*, 1909, 3, pt. ii.) records four lead borates, but the author finds that there are only two of definite chemical composition, viz., the triborate, $\text{PbO} \cdot 3\text{B}_2\text{O}_3$, formed by fusing a mixture of lead carbonate and boric acid and washing out the excess of boric acid with water, and the metaborate, $\text{Pb}(\text{BO}_2)_2 \cdot \text{H}_2\text{O}$, formed by precipitating a solution of a lead salt with an excess of a concentrated solution of borax. The precipitate produced by mixing cold solutions of lead nitrate and borax is of indefinite composition. The polyborate, $2\text{PbO} \cdot 3\text{B}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$, mentioned by Abegg is not formed under the conditions mentioned, the metaborate being produced. (See also *J. Chem. Soc.*, 1920, ii., 176.)—A. B. S.

Antimony trisulphide; Formation of the black modification of —. F. de Bacho. *Annali Chim. Appl.*, 1919, 12, 143–152.

WHEN red antimony trisulphide was dried for an hour at different temperatures between 150° and 300° C. no material differences were observed in the loss of weight at the different temperatures (1·12 to 0·87%); the change to the black modification occurred at 212° C. In a current of hydrogen sulphide the change to the black modification occurred at 207° C. By adding antimony trichloride to the red sulphide the temperature at which the change took place in carbon dioxide was lowered to 115° C. Metallic silver also has a favourable influence on the conversion. Ammonium chloride and antimony chloride promote the change to the black form when the red sulphide is boiled with water. (See also *J. Chem. Soc.*, 1920, ii., 183.)—C. A. M.

Metastannic acid; Soluble —. H. Kreis. *Schweiz. Chem.-Zeit.*, 1919, 389–390.

DURING the analysis of samples of tinned iron it was observed that no deposition of metastannic acid occurred when the turnings were dissolved in dilute nitric acid (sp. gr. 1·23). This was proved to be due to the protective action of colloidal ferric hydroxide formed by hydrolysis of the nitrate, and it was found that the presence of three parts of iron prevented the precipitation of ten parts of tin. (Compare Antony and Mondolfo, this *J.*, 1898, 1186.) (See also *J. Chem. Soc.*, 1920, ii., 182.)

—A. R. P.

Bismuth; Peroxides of —. R. R. Le G. Worley and P. W. Robertson. *Chem. Soc. Trans.*, 1920, 117, 63–67.

VARIOUS peroxides of bismuth were obtained by the action of chlorine, ammonium persulphate, or

potassium ferricyanide on bismuth trioxide in presence of boiling alkali hydroxide of different concentrations. In dilute solutions bismuth tetroxide was the only product, and was isolated from admixed trioxide and occluded alkali by repeated grinding with glacial acetic acid. Four modifications were recognised, viz., Bi_2O_4 (brown), Bi_2O_4 (purplish black), $\text{Bi}_2\text{O}_4 \cdot \text{H}_2\text{O}$ (brown), and $\text{Bi}_2\text{O}_4 \cdot \text{H}_2\text{O}$ (purplish black). All decompose at 160° C. and are soluble in nitric acid (sp. gr. 1·2) with liberation of oxygen. Another variety of tetroxide, $\text{Bi}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ (yellow), is formed together with a pentoxide, $\text{Bi}_2\text{O}_5 \cdot \text{H}_2\text{O}$, by the action of chlorine on Bi_2O_3 in boiling concentrated alkali. Finally a hexoxide, Bi_2O_6 , was obtained in small quantities along with Bi_2O_4 by the action of ammonium persulphate or potassium ferricyanide on the trioxide suspended in boiling concentrated alkali. It was isolated by continued extraction with warm nitric acid (sp. gr. 1·2), in which it is insoluble. The hexoxide slowly loses oxygen at ordinary temperatures and darkens in colour.

—G. F. M.

Cerium carbide; Behaviour of — towards nitrogen. F. Fichter and C. Schölly. *Helv. Chim. Acta*, 1920, 3, 164–172.

FINELY-divided cerium carbide may be prepared by heating a mixture of cerium dioxide (1 mol.) and carbon (6 atoms) in a graphite tube in an electric vacuum-oven at 1600° C. In spite of its apparent similarity to calcium carbide, it does not yield at 1250° C. with nitrogen any compound which contains both carbon and nitrogen, but the carbon is replaced by nitrogen with the formation of cerium nitride. The possibility of the formation of cyanides and cyanamides from carbides appears to exist solely in the groups of the alkali and alkaline-earth metals and not in that of the earth metals; it does not depend on the type of carbide, but on the nature of the metal. Cerium carbide also reacts with ammonia at 1250° C. yielding the nitride, but the action is slower and less complete than when nitrogen is used.—H. W.

Uranium; Violet compounds of —. J. Aloy and E. Rodier. *Bull. Soc. Chim.*, 1920, 27, 101–105.

THE production of violet compounds of uranium described by Aloy (this *J.*, 1901, 480) is shown to be a general reaction, and does not necessarily involve the action of light. Such compounds are obtained whenever a uranous and a uranic salt are present together at the requisite temperature in a neutral or feebly acid medium. (See further *J. Chem. Soc.*, 1920, ii., 182.)—W. G.

Zirconium monoxide; Question of the existence of —. R. Schwarz and H. Deisler. *Ber.*, 1920, 53, [B], 1. (Compare this *J.*, 1920, 62 A.)

A RECOGNITION of similar work by Wedekind (this *J.*, 1913, 197).—J. C. W.

Carbon monoxide. Müller. See IIa.

Phosphoric acid. Stutzer. See XXIII.

PATENTS.

Sulphuric acid; Apparatus for making —. H. V. Welch. Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,328,552, 20.1.20. Appl., 1.10.18.

SULPHURIC acid mist present in chamber gases is removed by circulating the gases through an electrical precipitator connected to the chamber by inlet and outlet tubes, and provided with means for maintaining a film of dilute sulphuric acid in contact with the circulating gases.—L. A. C.

Hydrofluoric acid; Process for the removal of — from phosphoric acid. W. H. Ross, Washington, D.C. U.S. Pat. 1,329,273, 27.1.20. Appl., 26.7.19.
 Calcium chloride, equivalent in amount to the fluorine present, is added to the concentrated phosphoric acid solution thereby precipitating the fluorine.—S. S. A.

Ammonia; Production of — from atmospheric nitrogen. General Chemical Co., Assignees of F. W. de Jahn, New York, Eng. Pat. 120,516, 28.2.18. (Appl. 3607/18.) Int. Conv., 3.11.17.

REGULATED quantities of steam and air are introduced into an incandescent material to obtain a gaseous mixture of approximately 1 vol. of nitrogen to 3 vols. of gas consisting of hydrogen and carbon monoxide, and the mixture, after removal of dirt, sulphur, and the like, is passed together with regulated quantities of steam over a catalyst at the required temperature and at the ordinary pressure to oxidise carbon monoxide to carbon dioxide and to form hydrogen. The resulting mixture is subjected to a pressure not exceeding 1100 lb., and whilst under pressure carbon dioxide and sulphur impurities are removed by water scrubbing, carbon monoxide and other sulphur impurities are eliminated by treatment with caustic soda, and oxygen and carbon monoxide by means of cuprous material such as cuprous ammonium carbonate free from chlorides or sulphates. Traces of moisture are then removed, and the residual mixture containing nitrogen and hydrogen is passed over a catalyst consisting of iron or other suitable metal together with sodium, at a temperature of 450° C. under a pressure of not more than 1400 lb. The accumulated inert rare gases are removed from the ammonia produced. The pressure of the gases is used in raising the hot alkali solution required for the removal of the carbon monoxide.—S. S. A.

[*Synthesis of ammonia.*] *Process of making a mixture of nitrogen and hydrogen.* C. Ellis, Montclair, N.J., Assignor to C. S. Lutkins, Rye, N.Y. U.S. Pat. 1,327,029, 6.1.20. Appl., 18.5.16.

A MIXTURE of water-gas and producer-gas is prepared in a single operation, and as much as possible of the contained carbon monoxide is removed by liquefaction. The residual gas is passed over lime and an iron compound to remove sulphur, and sufficient hydrogen is then added to produce a mixture containing hydrogen and nitrogen in the proportion of 3 to 1 by volume. The added hydrogen is previously treated to remove substances injurious to catalysts employed in the synthesis of ammonia.

—W. E. F. P.

Ammonia; Production of synthetic — from air or nitrogen. R. F. Gardiner, Clarendon, Va. U.S. Pat. 1,323,082, 13.1.20. Appl., 13.1.19.

Air is brought into contact with an alkaline solution containing a metal from which nascent hydrogen is being evolved.—S. S. A.

Ammonia; Synthetic production of —. H. C. Greenwood, London. U.S. Pat. 1,329,397, 3.2.20. Appl., 15.2.18.

Is the synthetic production of ammonia, the incoming gases are heated by the issuing gases in a heat interchanger through which at least one of the gas streams flows at a velocity greater than the critical velocity.—S. S. A.

Ammonium salts; Production of —. W. S. Curphey, London. Eng. Pat. 137,315, 21.8.18. (Appl. 13,596/18.)

For the production of ammonium salts, e.g., ammonium sulphate or a mixed product ("Burkheiser salt") containing sulphate and sulphite, ammoniacal liquor is heated in an apparatus comprising two distillation vessels combined to form a

two-stage still. The gas evolved in the first stage contains a portion of the ammonia together with hydrogen sulphide, carbon dioxide, and at least part of the volatile organic impurities, and is absorbed in an acid liquor, e.g., sulphuric acid. The products of the reaction are withdrawn from the absorber and filtered, and the still acid liquor is passed into a second absorber and to it a solution of sulphurous acid or bisulphites may be added. The ammoniacal liquor which has been heated in the first stage is passed through a device, in which it is mixed with lime, into the second distillation vessel, and the relatively pure ammonia obtained at this stage is absorbed in the liquor contained in the second absorber. The precipitated salts obtained are removed from the absorber and drained, and the liquor is collected and returned to the first absorber.—S. S. A.

Ammonia; Manufacture of salts of —. Amsterdamsche Superfosfaatfabriek, Amsterdam, Holland. Eng. Pat. 138,002, 21.5.19. (Appl. 13,108/19.) Int. Conv., 10.2.19.

AMMONIA is absorbed in a concentrated solution of the required ammonium salt contained in a cooled iron absorber which is connected to a column and scrubber through which a portion of the ammonium salt solution, cooled to atmospheric temperature, is circulated for the recovery of any ammonia which escapes solution in the absorber. The resulting ammoniacal solution of the salt is passed into a wooden vat, neutralised with acid, and pumped thence to an evaporating plant.—S. S. A.

Ammonium sulphate; Production [purification] of —. W. A. Sloss, Toledo, Ohio. U.S. Pat. 1,328,312, 20.1.20. Appl., 22.5.19.

COMMERCIAL ammonium sulphate is purified by treatment with ammonia at a temperature above that at which pyridine becomes volatile.

—W. E. F. P.

Caustic potash; Manufacture of —. C. L. Higgins, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 137,632, 6.2.19. (Appl. 2912/19.)

To prevent the deleterious action of caustic potash solution on metallic evaporating apparatus, the surface of the apparatus which comes into contact with the caustic potash is made of or covered with gold.—S. S. A.

Iron compounds; Process of manufacturing —. R. S. Penniman, jun., and N. M. Zoph, Berkeley, Cal., Assignors to West Coast Kalsomine Co., Cal. U.S. Pat. 1,327,061, 6.1.20. Appl., 20.6.17.

METALLIC iron is immersed in a solution of a ferrous salt, the solution is heated, and an oxidising agent is introduced.—S. S. A.

Potassium; Process of obtaining combined — from greensand. T. C. Meadows, New York, M. Hauber, jun., West Haverstraw, and H. W. Charlton, New York. U.S. Pat. 1,327,161, 6.1.20. Appl., 6.12.18.

A MIXTURE of greensand and lime is digested with an aqueous solution containing sufficient calcium chloride to react with substantially all the potassium present in the greensand, at a pressure not exceeding 200 lb. per sq. in. and at a corresponding temperature, until a solution containing more than 2% of potassium chloride is obtained together with a valuable sludge material.—S. S. A.

Potassium; Process of producing combined — from greensand. H. W. Charlton, New York, Assignor to American Potash Corporation. U.S. Pat. 1,329,369, 3.2.20. Appl., 12.11.18.

POTASSIUM compounds are extracted from green-

sand by agitating a mixture of the material with more than 50% of its weight of lime and more than three times its weight of water under a pressure exceeding 150 lb. per sq. in.—L. A. C.

Potassium salts; Process of obtaining — from liquids containing the same. Process of obtaining potassium salts from saline waters. Process of recovering potassium sodium sulphate and other potassium salts from saline waters. G. B. Burnham, Berkeley, Cal. U.S. Pats. (A) 1,328,416, (B) 1,328,417, and (C) 1,328,418, 20.1.20. Appl., (A) 18.9.16, (B and C) 1.7.18.

(A) A solution containing sodium, potassium, sulphate, and chloride ions is evaporated to approximate saturation with potassium sodium sulphate, and then cooled to below 44° C. to saturation with potassium chloride; the salts deposited are removed and the solution is evaporated at about 44° C. again to saturation with potassium sodium sulphate and cooled to approximate saturation with potassium chloride. After separation of the deposited salts, the solution is cooled further, and potassium chloride is deposited in crystalline form. (B) A solution containing sodium, potassium, chloride, sulphate, and carbonate ions is evaporated to crystallise out hanksite, potassium sodium sulphate, and potassium sodium sulphate together with a carbonate, in successive stages; the crystals deposited are separated after each evaporation and the final liquor is cooled, whereby potassium chloride is deposited. (C) A solution containing potassium, sodium, chloride, and sulphate ions is cooled to crystallise out Glauber salt; the liquor, after separation of the crystals, is evaporated in two stages, the first to crystallise out sodium chloride, and the second to crystallise out sodium chloride and potassium sodium sulphate.—L. A. C.

Wood ashes; Apparatus for extracting lye from —. W. P. D. Moross and J. C. Costello, Chattanooga, Tenn. U.S. Pat. 1,328,096, 13.1.20. Appl., 2.8.17.

THE apparatus comprises a tray or receptacle on which the ashes are placed, provided with a movable lid which serves as a deflector during agitation. The ashes are mixed with water and agitated by steam introduced into the receptacle through a series of jets. The liquor drains into a steam-heated gutter and is collected.—S. S. A.

Calcium carbonate; Process of grinding — and product thereof. J. H. Ryan, Assignor to D. R. Seaman, Chicago, Ill. U.S. Pat. 1,328,299, 20.1.20. Appl., 24.3.19.

CALCIUM carbonate in a relatively fine condition is ground in the presence of sufficient water to form an emulsion or plastic mass with the very fine particles present and hold the coarser particles in suspension, whereby the whole of the material is reduced to an impalpable powder.—L. A. C.

Borax; Process of recovering — from saline waters. G. B. Burnham, Borosolway, Cal. U.S. Pat. 1,328,614, 20.1.20. Appl., 30.6.19.

A solution containing sodium sulphate, carbonate, and borate is cooled to crystallise the sodium sulphate and carbonate; the crystals are separated, and the liquor maintained cold, whereby crystals of borax are deposited.—L. A. C.

Calcium fluoride precipitate; Process of obtaining —. W. S. Chase, Lakewood, Ohio, Assignor to National Carbon Co. U.S. Pat. 1,329,072, 27.1.20. Appl., 1.3.17.

AN insoluble metallic fluoride, e.g., calcium fluoride, is precipitated by adding a concentrated solution of some other compound of the metal to a concentrated solution of hydrofluoric acid.—S. S. A.

Cyanide-producing apparatus; Process of producing cyanide. W. D. Mount, Saltville, Va., Assignor to Nitrogen Products Co., Providence, R.I. U.S. Pats. (A) 1,329,721 and (B) 1,329,722, 3.2.20. Appl., 26.4.18 and 4.10.18.

(A) THE apparatus comprises a cyanising retort provided with means for gradually moving the treated material out of the retort at a temperature below that at which it congeals, and a mechanically operated toothed device for breaking off the material in fragments as ejected from the retort. (B) A material, part of which is in the solid phase, is so disposed as to provide interstices throughout its mass. It is heated, and treated by passing a substance in the gaseous phase through the interstices, whereby a partial reaction is promoted between the two substances, with formation of a compound which tends to liquefy at the temperature employed; by causing a circulatory movement of the resulting mass this compound is cooled and congealed. The mass is then broken into fragments which are cooled in a stream of nitrogen to a temperature at which the reaction product is unoxidisable.—S. S. A.

Thorium; Art of recovering —. O. N. Berndt, Assignor to Lindsay Light Co., Chicago, Ill. U.S. Pat. 1,329,747, 3.2.20. Appl., 26.6.19.

A PHOSPHATIC thorium compound is treated with fuming sulphuric acid, thereby converting the thorium into an insoluble compound.—S. S. A.

Permanganate; Process for the production of —. R. E. Wilson, Cambridge, Mass. U.S. Pat. 1,330,032, 3.2.20. Appl., 27.9.18.

A CATALYST is employed to accelerate the reaction in which more highly oxidised manganese compounds are prepared from less oxidised compounds by treatment with a halogen.—S. S. A.

Hydrogen; Manufacture of —. H. E. F. Gool-Adams and H. C. Greenwood, London, Eng. Pat. 137,340, 24.1.18. (Appl. 1383/18.)

HYDROGEN practically free from carbon monoxide is obtained by passing a mixture of water-gas (or similar gas) and steam through a series of catalyst chambers separated by intermediate lime containers, the alternate catalysis (oxidation of carbon monoxide) and absorption (of carbon dioxide) being effected without fall of temperature by passing the gas mixture through a heat-interchanger before and after the series of operations.—W. E. F. P.

Hydrogen gas; Means for charging retorts or apparatus with spathic ore for the manufacture of —. W. J. and W. R. Bates, Silverdale, Staffs. Eng. Pat. 137,674, 13.3.19. Appl. 6252/19.)

PERFORATED metal cages, of appropriate mesh, are employed as containers for graded spathic ore. The charged cages are placed one above the other in the retort, so that the fineness of the ore decreases from the top downwards. (Reference is directed to Eng. Pat. 12,117 of 1912; this J., 1912, 1079.)

—W. E. F. P.

Minerals [sulphur] from ores; Apparatus for extracting —. G. M. Shires, Houston, Tex. U.S. Pat. 1,328,210, 13.1.20. Appl., 29.11.18.

AN apparatus for extracting sulphur from ore consists of a number of connected heater drums, arranged one above the other, and a cylindrical container disposed beneath and communicating with the bottom drum. A heating fluid is introduced into each of the drums, and means are provided for charging the ore into the top vessel and for separating the sulphur from the gangue in the container.—W. E. F. P.

Graphite [from kish]; Process for producing flake — S. W. Osgood, Assignor to N. C. Kenner, Chicago, Ill. U.S. Pat. 1,328,845, 27.1.20. Appl., 1.3.16.

Improve flake graphite, separated from kish, is treated to remove iron particles and gritty material and then graded by air flotation.—W. E. F. P.

Iodine; Apparatus for purifying — R. M. Carter, Baltimore, Md., Assignor to U.S. Industrial Alcohol Co. U.S. Pat. 1,329,457, 3.2.20. Appl., 21.12.18.

A vapourising vessel is provided with means for introducing a heated gaseous medium and with an internal condenser through which cold water is circulated.—W. E. F. P.

Cyanogen compounds; Process of producing — J. C. Clancy, Freeport, N.Y., Assignor to The Nitrogen Corporation, Providence, R.I. U.S. Pat. 1,329,652, 3.2.20. Appl., 12.6.17.

VIII.—GLASS; CERAMICS.

Refractories for glassworks' use; Specifications for — W. J. Rees. Trans. Ceram. Soc., 1918-9, 18, 420—431.

THE Refractories Research and Specifications Committee of the Society of Glass Technology have drawn up provisional specifications for clays for use in glass manufacture (this J., 1919, 137 A). In the discussion W. R. Ormandy pointed out that the specification for glass pots is too severe, that it places too much emphasis on the total porosity and too little on the size of the pores. J. W. Mellor confirmed this, and considered that the proposed specification sets up impracticable ideals, and that it would immobilise manufacturing processes.

—A. B. S.

Blue glass. J. W. Mellor. Trans. Ceram. Soc., 1918-9, 18, 478—480.

WHEN glass is stained blue by the addition of cobalt oxide to the batch, an incandescent filament viewed through it appears red. The addition of a small percentage of chromium oxide neutralises the red rays so that only blue rays are transmitted. Photographs of the absorption spectra are given.

—A. B. S.

Silica bricks; Constitution and micro-structure of — and changes involved through repeated burnings at high temperatures. H. Insley and A. A. Klein. U.S. Bureau of Standards, Tech. Paper No. 124, July 11, 1919. 31 pages.

COMMERCIAL silica bricks which have been reheated repeatedly by use in kilns contain quartz, cristobalite, and tridymite, with small amounts of pseudowollastonite (CaSiO_3) and glass. The greater the proportion of flux present the more rapid is the inversion of the silica, but 6% or more lime makes the bricks too fusible. The lime added during manufacture acts more as a flux than as a bond, the strength of the bricks being chiefly due to the interlocking crystals of quartz, cristobalite, and tridymite. The extent to which a silica brick will expand when in use may be judged from the extent to which the quartz has been converted into cristobalite or tridymite. Bricks low in quartz should show very little expansion in use. The complete

inversion of quartz to cristobalite gives an increase in volume of 13.6% ; the inversion into tridymite gives an increase of 16.8% . The permanent expansion of most silica bricks is only 10 or 11% by volume. The proportion of unaltered quartz may be estimated by grinding the bricks until the powder will pass through a 200-mesh sieve, immersing the powder in a liquid of refractive index 1.51, viewing it through a microscope magnifying 400 diameters and fitted with a camera having a plain glass plate carrying a sheet of tracing paper instead of the usual ground glass screen. The outlines of the grains are traced on the paper and then cut out; those having an index of refraction higher than the liquid are weighed separately; they represent the proportion of quartz present. The grains are next immersed in a liquid having an index of refraction equal to the mean index of either tridymite or cristobalite, whichever is in excess in the specimen of brick being examined, in which case the corresponding grains will be rendered invisible. Thus, if the first test showed 30% of quartz and 70% of cristobalite plus tridymite, and it was judged that there was more cristobalite than tridymite, the grains would be immersed in a liquid with a refractive index of 1.485 in which the cristobalite is invisible. If the grains of quartz plus tridymite left were in the proportions of 60:40, the actual amount of tridymite would be $40 \div 60 \times 30 = 20\%$, and the brick would be composed of quartz 30%, tridymite 20%, and cristobalite 50%. Five determinations should be made on each sample. The error may reach 5% or even higher, as glass and calcium metasilicate have higher indices than quartz, and are therefore included as quartz. When using a commercial mixture of silica rock and lime, the constitution of the bricks produced is dependent on the duration and temperature of the burning; the longer the heating at high temperatures (below 1470° C.) the greater the amount of tridymite present. An all-tridymite brick would be technically ideal, but too costly. Detailed descriptions of 14 bricks made by different American manufacturers and one German manufacturer are given. All these bricks have a porphyritic structure made up of phenocrysts or coarse fragments and ground mass, this structure being entirely due to the method of grinding the material.

—A. B. S.

Silica bricks; Factors influencing the properties of — (I.) A. Scott. Trans. Ceram. Soc., 1918-9, 18, 481—496.

A STUDY of the effects of the impurities in silica bricks on the inversion of quartz to cristobalite and tridymite, and on the properties of silica bricks generally. Vein-quartz was used as the standard on account of its purity, though it is unsuitable for the manufacture of silica bricks; this quartz was mixed with about 2.5% of other material and compressed into bricks which were then fired in a silica brick kiln at cones 11, 16, and 19 respectively, and afterwards examined. The inversion of the quartz is affected by the nature and amount of impurities, the grain-size of the quartz, and the temperature and duration of firing, and is increased if the firing temperature is increased or the period of firing is prolonged, especially at cone 20 (1530° C.). Iron oxide and lime appear to have the greatest influence of all single oxides, whilst alumina has a very small effect. The effect of a second oxide is to facilitate the inversion, especially with iron oxide and either lime or alumina. The best results are obtained when the bonding material forms a relatively fusible mixture with finely divided silica. Carbon appears to have no influence on the inversion. Both the apparent and true sp. gr. vary directly as the firing temperature. The porosity varies irregularly when only one metallic oxide is present, but re-

gularly when two or more are present. After-expansion or permanent increase in volume must be determined by reheating to at least cone 20. Heating to cone 26 for 2 hours appears to complete the inversion of quartz in small test-pieces. Mixtures of silica with lime and iron oxide give the smallest expansions; the next lowest are those with silica and either iron oxide or lime separately. Alumina and titanite oxide both give high values, but if another oxide is present the values are much lowered. The expansion with a fireclay bond is low. The presence of carbon does not greatly alter the after-expansion; in three out of four cases tried the bond containing carbon gave slightly lower values. The liability to spalling may be judged from the ratio of expansion determined by direct measurement to the expansion calculated from the sp. gr. determinations. In general, bonds containing magnesia have less spalling tendency than those containing lime. The presence of carbon, alumina, and fireclay seems to increase the spalling tendency. The greatest reduction in refractoriness occurs on the addition of lime or magnesia or a mixture of lime, iron oxide, and either carbon or titanium oxide. When the only metallic oxide present is lime or magnesia the reduced refractoriness is due to the fusion of the silicate. When alumina or iron oxide is present, or both, the matrix of fine silica and the rock fragments fuse simultaneously, and at the same temperature as pure silica. Fireclay acts similarly. Carbon in the presence of ferric oxide slightly reduces the refractoriness.—A. B. S.

Silica products; Manufacture of —. A. Bigot. Trans. Ceram. Soc., 1918-9, 18, 354-361. (See this J., 1918, 335 A, 695 A.)

Rock crystal, fused quartz, chalk flint, and chalcedony fall to powder on prolonged heating at 1450°-1650° C., and are unsuitable for silica bricks. Quartzites, ferruginous sandstones (3-8% Fe₂O₃), and aluminous rocks, on the contrary, remain compact, even when heated for several days at 1500° C. The behaviour of the quartzites is attributed to the small proportion of clay present, which unites the particles of silica and prevents them from falling apart. The following tests etc. are recommended: complete analysis (there should be 2-5% of alumina); porosity test, i.e., increase in weight after immersion for 24 hours in water; expansion on heating: materials which expand 10% are superior to those which expand 15%; crushing test curve by Bodin's method (this J., 1918, 695 A); compactness of the material after heating to 1710° C.; if it remains compact the expansion, porosity, and loss on heating are determined. The selected rock should be ground in a jaw crusher followed by two pairs of crushing rolls, so as to produce angular grains—the largest of which should pass through a No. 3 or No. 4 sieve—together with a suitable proportion of fine powder. Water and 2% of lime are added to the paste and the mixture pugged for 15-20 mins. The paste is moulded by hand or in hydraulic presses, dried rapidly, raised to 1500° C. in 5 or 6 hours, held at this temperature for 4 hours and then burned at as high a temperature as possible. The glassy mass produced by combination of the lime with the clay and fine silica should not be too fusible or the bricks will not be sufficiently refractory, and will be too sensitive to changes in temperature. Hydraulically pressed bricks are less porous and more durable than those moulded by hand in a small lever press.—A. B. S.

Silica materials; New experiments on —. A. Bigot. Trans. Ceram. Soc., 1918-9, 18, 362.

Pure silica, including fused hyaline quartz, other types of quartz, and chalk flints fall to powder when heated for four hours at 1450° C., and are, therefore, unsuitable for the manufacture of silica

bricks. Silica materials (including some quartzites and quartzose rocks and some dense flints) containing 2-5% of clay, iron oxide, and a small proportion of magnesia and lime do not fall to pieces on prolonged heating, and are suitable for making silica bricks if their expansion at 1710° C. is not too great (about 10%, see preceding abstract). Silica rocks which contain more than 3% Al₂O₃ become too fusible after the addition of 2% of lime, and so are not suitable for the manufacture of silica bricks.—A. B. S.

Silica brick from the roof of an open-hearth furnace. J. E. Stead. Trans. Ceram. Soc., 1918-9, 18, 389-398.

A SILICA brick taken from the roof of an open-hearth furnace at Middlesbrough had been reduced during use from 12×6×3 in. to 12×2½×2½ in. The results of the chemical and microscopical examination of the brick confirmed those obtained by E. Rengade (this J., 1918, 372 A).—A. B. S.

Silica brick from roof of a basic open hearth furnace after 135 charges; Seasoned —. C. S. Graham. Trans. Ceram. Soc., 1918-9, 18, 399-406.

EXAMINATION of a silica brick taken from the transverse centre of the roof of a 45-ton basic open-hearth steel furnace after 135 charges gave results confirming those of Stead and Rengade (see preceding abstract).—A. B. S.

Refractory materials; Standardisation of tests for —. (Part III.) *Penetrative action of slags.* Report of Committee. Trans. Ceram. Soc., 1918-1919, 18, 516-517.

THE method of Nesbit and Bell (Proc. Amer. Soc. Testing Materials, 1918, 18, 345) is recommended. A ring of stoneware is cemented to the firebrick under test by means of a thin film of grog and sodium silicate. The receptacle so formed is filled with slag, and the whole is fired at the desired temperature for the desired time (say, 4 hrs.). The block and its contents are afterwards sawn in half and examined.—A. B. S.

Clay; Osmotic purification of —. W. R. Ormandy. Trans. Ceram. Soc., 1918-9, 18, 327-339.

WHEN a clay slip is subjected to the action of an electric current it collects at one pole in a purer form, and is dried to a considerable extent even when collected under water. The rate of collection is increased by adding a little alkali (or sometimes organic matter) to the slip. Under suitable conditions such treatment produces cakes of ball clay containing only 18% of water. The remarkable dryness of the clay is due to the particles forming a series of capillaries through which the water, travelling in a contrary direction to the clay, is expelled at a considerable velocity. On adding a suitable amount of soda or other suitable electrolyte the positive particles are neutralised and precipitated whilst the negative ones remain in suspension, and so may be run off and separated. The purified slip is then passed into an osmosis machine in which the nearly dry clay is deposited as described. The product is more plastic, and has a greater shrinkage than crude clay, and it sinters at a temperature as much as 300° C. lower.

—A. B. S.

[Earthenware] bodies; Preparation of —. R. L. Johnson. Trans. Ceram. Soc., 1918-9, 18, 321-326.

IT is possible to produce equally good bodies or ware from materials ground in cylinder mills as from those ground in pan-mills, but there are marked differences in cost. For flint of good quality and washed to a fine degree, the cost of grinding

in a pan-mill is no more than for grinding in a cylinder mill producing a material of the same quality. For a coarser, lawned product cylinder grinding is cheaper. Crazing may result if coarser flint replaces a finer one in an earthenware body and glaze. The setting of flint in the ark or blunger may be prevented by finer washing. The construction of the filter-presses used may have a serious effect on the plasticity of the clay. Wooden presses are preferable; they should produce a thin, uniform cake. The cakes should be stored for 24 hours before use. To make a really good white earthenware body it is necessary to develop the plasticity of the material as fully as possible, and this is difficult when a large proportion of non-plastic or milled material is present. Both ball and china clays should be blunged to a thick slip, avoiding unduly prolonged blunging. The flint and stone should be washed very fine and stored as long as possible in a slip state (32 oz. or more per pint). Any scrap material added should be in the form of a thicker or heavier slip than the newly mixed body, as few white scraps as possible being used.

—A. B. S.

Bone china body; Recent research on the —. J. W. Mellor. Trans. Ceram. Soc., 1918-9, 18, 497-509.

BONE china is composed of bone ash (tricalcium phosphate), china clay, and Cornish stone. On grinding the Cornish stone and bone ash with water and on evaporating the water used in preparing the body slip, hydrolysis occurs, and the product becomes plastic. Bone china body cannot be matured by prolonged storage. When bone china body is fired in a kiln the shrinkage is roughly proportional to the temperature, up to the finishing point, after which the body expands on further heating. This expansion is due to the dissociation of the bone ash or its decomposition by carbon, under reducing conditions, with evolution of phosphorus. There is less than 1½% of iron in a bone china body, but in firing the ware it combines with phosphorus from the bone ash forming greenish-blue, blue, or brown iron phosphate. Blue china can readily be made by enclosing charcoal or other organic matter in the sagger in which the ware is fired or by using a bone ash containing sufficient carbonaceous matter. It can also be obtained with bone ash free from carbon and with ware fired wholly in an oxidising atmosphere. In some samples of bone ash the carbonaceous matter burns out readily and at a temperature much below the decomposition point of bone ash; other samples give trouble because vitrification of the ware sets in before all the carbonaceous matter has burnt away; this difference in behaviour appears to be due to the manner in which the bones are calcined. It is shown that the range of white bone china bodies is extremely limited, and that outside this range an extraordinary variety of tints is developed. The smaller the proportion of stone and the greater the proportion of clay in a bone-china body the greater is the tendency to form blue ware. The presence of a high proportion of alkalis thus hinders the conversion of calcium phosphate into iron phosphate. If, however, the proportion of Cornish stone is excessive the body blisters or "bloats." Even the use of a more moist sample of stone may spoil the ware by disturbing the balance essential to white ware, and blue china must have been very frequently produced by assuming that the Cornish stone used contained only 10% of water when, in reality, it contained 20% or more. A greater variation is permissible in the bone ash used than with either stone or clay. When the stone is deficient in feldspar, the blue china is in so critical a condition after passing through the glost oven that oxidation may occur in the enamel kiln with pro-

duction of brown stains of ferric phosphate. Sometimes white iron phosphate in chinaware is so sensitive that it oxidises to the brown form on mere exposure to air. This brown ware is very liable to spit in the enamel kiln (this J., 1917, 550). The variation in the composition of mixtures forming a satisfactory glazed bone china is very limited, due to the fact that glazed ware rich in clay, i.e., glazed blued ware, tends to craze badly, and also to the tendency to blister of ware which is rich in stone and bone ash. Alumina and iron and alkalis appear to facilitate the decomposition of the bone, but they fix the phosphate before it has time to blister. Alkalis also aid in vitrifying the body, but the free quartz in the stone acts as an acid decomposing the bone ash and any aluminium phosphate.

—A. B. S.

Bone ash; Note on apatite substituted for — [in bone china bodies]. N. B. Davis. Trans. Ceram. Soc., 1918-9, 18, 378-381.

CANADIAN mica-apatite containing CaO 55.60%, P₂O₅ 39.24%, SiO₂, Fe₂O₃, Al₂O₃ each 0.72%, MgO 0.35%, Na₂O, K₂O each 0.25%, Cl 0.5% and F 3.10% was substituted for bone ash in four typical china bodies. The mixture showed excellent casting properties and plasticity, but all the pieces were deformed when fired at cone 12 (1350° C.). The greatest translucency was developed at cone 9 (1280° C.).

Refractory material. E. D. Frohman, Pittsburgh, Pa. U.S. Pat. 1,327,758. 13.1.20. Appl., 26.4.19. The material consists of a mixture of finely-divided

dry fireclay, silicious material, and "sulphite pitch."—L. L. L.

Refractory material and process of making same. T. Sheard, Lakewood, and H. E. Wetherbee, Cleveland Heights, Ohio, Assignors to The Dolomite Products Co., Cleveland, Ohio. U.S. Pat. 1,329,431, 3.2.20. Appl., 19.9.18.

DOLOMITE is calcined, and a portion of the lime present is converted into a solution of calcium chloride, which is separated. The residual solid is suitable for use as a refractory material.—A. B. S.

Plastic [insulating] composition. F. Richard and F. M. Brady, Cleveland, Ohio. U.S. Pat. 1,329,094, 27.1.20. Appl., 2.5.17.

A PLASTIC, insulating composition is prepared by mixing silica and carbon with lesser quantities of alumina and ferrous oxide, together with water and a binding agent, drying the mixture at 100° F. (38° C.), then heating to 800°–900° F. (430°–480° C.) to burn off the carbon, and finally heating to incipient fusion of the ferric oxide, leaving the greater part of the silica unfused.—A. B. S.

Porcelain, stoneware and the like; Process of firing —. E. Enke, Breslau. Ger. Pat. 314,585, 2.11.15.

HIGHLY-HEATED secondary air is introduced under high pressure into the fire-gases as they leave the combustion chamber. The exhaust gases are drawn away exclusively by this hot secondary air so that the furnace works without a chimney draught. The air introduced under high pressure causes a better mixing of the smoke particles, and consequently a better combustion, the latter being also improved by the fact that the secondary air introduces additional heat.—J. F. B.

Drying machine for clay. U.S. Pat. 1,329,082. See 1.

IX.—BUILDING MATERIALS.

Salt mixtures as preservatives for wood against fungus and decay. F. Moll. Z. angew. Chem., 1920, 33, 39–40.

THE author gives a short history of the development of the use of inorganic salts for impregnating wood for preserving it against decay, the attacks of insects and fire. Wolman introduced the use of salts of organic acids and reduced the temperature of treatment. Subsequently he patented the use of salts of heavy metals with sodium fluoride (Eng. Pat. 17,534 of 1906; this J., 1907, 968). He also combined with the use of sodium fluoride that of water-soluble organic compounds known to have antiseptic properties (Eng. Pat. 19,241 of 1906; this J., 1907, 529). Wolman's mixtures can be varied in many ways for different purposes. To fix such substances as phenol, naphthol, and cresol in the wood, a chroming treatment is now employed. The type of mixture frequently used at present contains 70% of sodium fluoride and 30% of phenol-chromium salt compound. A chronological bibliography is given.—E. H. R.

PATENTS.

Cement; Mixing of — and apparatus therefor. N. C. Johnson, New York. Eng. Pat. 127,560, 9.4.19. (Appl. 9030/19.) Int. Conv., 23.5.18.

BATCHES of cement, with or without other ingredients, are mixed with water in an upright bowl which is rotated at such a speed—1500 revs. per min.—as to cause the mixture to be driven centrifugally upwards, outwards, and along the walls of the bowl at a high velocity until it is deflected

by concave baffles and projected in a smoothly-flowing stream to the centre of the bowl. The paths taken by the contents may be varied by altering the shape of the bowl, and the number, shape, and position of the deflectors. The crushing strengths of mortars and concretes prepared as described are stated to be considerably superior to those of similar products mixed by hand.—A. B. S.

Road or like covering material; Composition for use as a dust-proof and waterproof — and the method of making the same. R. Illemann, Glasgow. Eng. Pat. 138,017, 20.6.19. (Appl. 15,534/19.)

A BITUMINOUS composition for surfacing roads is made by adding bituminous oil or tar or a mixture of non-oxidising oil, such as creosote, and pitch to dried stone-dust, heating to remove light volatile oils, and then agitating so as to obtain a uniform mixture. (Reference is directed to Eng. Pats. 1737 of 1871, 17,483 of 1887, 17,153 of 1890, 21,043 of 1905, 3749 and 24,829 of 1906, 9929 of 1909, 25,465 of 1910, and 1455 of 1913 (this J., 1909, 1315; 1911, 1388; 1914, 201.)—A. B. S.

(A) Wood is immersed in superheated water under pressure until its soluble contents are dissolved and the wood completely sterilised; it is afterwards dried under conditions which prevent hardening and enable the resins to permeate the individual fibres, whilst "tanning colloidal substances" extracted from the wood are deposited on the fibres. (B) A tanned wood, having its gummy sap-matters removed and its natural preservatives (tannins) uniformly distributed. (C) Wood is immersed in superheated water and then heated so as to dry it without hardening the resins. The wood may be subjected to a vacuum prior to immersion. (D) Timber is subjected simultaneously to live steam under pressure and to a dry heat, and then to a dry heat whilst periodically removing the accumulated moisture. (E) A wood from which the gummy sap-matters have been removed and the individual fibres permanently enlarged by impregnation with the natural preservatives in the wood and with a foreign preservative. (F) Wood which has been sweated and softened by heat is subjected consecutively to a vacuum, steam, a further vacuum, and hot water to remove all soluble constituents. The water is then removed and the wood dried. (G) Wood is heated by radiation, sweated, subjected consecutively to steam under pressure, vacuum, superheated water, a further vacuum, to dry heat at a high temperature, and finally to a moderately-heated moist atmosphere. (H) Wood is subjected to a moderately-heated moist atmosphere without pressure, then to saturated steam until the sappy matters are dissolved; the pressure is then gradually reduced to below atmospheric pressure, and the wood is finally dried at atmospheric pressure without heat. (I) Wood is subjected to live steam under pressure, then to a partial vacuum, and is finally dried in a moderately-heated moist atmosphere at atmospheric pressure. (J) Wood is mixed with a heat-absorbent, then sweated, surrounded by steam, subjected to dry heat, and finally cooled in a moderately-heated moist atmosphere. (K) Wood is placed in a sweating chamber and subjected to a moderately-hot, moist atmosphere; it is then

subjected successively to steam under pressure in an autoclave, to dry heat in an "equalising chamber," and to a moist moderately-heated atmosphere in a cooling chamber.—A. B. S.

Mica schist for lining cupolas and steel converters. P. G. H. Boswell. Trans. Ceram. Soc., 1918-19, 18, 382-388.

IN America mica schist is used instead of ganister for lining cupolas and steel converters. The material is of Cambrian age, fairly hard, foliated, but fine grained and compact. Microscopical examination shows that the material is a quartz-schist rather than a mica schist; it contains 69% of quartz, a considerable amount of muscovite mica, and some potash feldspar. The rock contains SiO_2 81.55%, Al_2O_3 10.01%, Fe_2O_3 2.21%, $\text{Na}_2\text{O} + \text{K}_2\text{O}$ 3.46%, $\text{CaO} + \text{MgO}$ 0.41%. It is built into the walls of converters and cupolas inside the firebrick casing, the blocks being set with the cleavage edges forming the inner wall. Fireclay is generally used as mortar, but occasionally the crushed rock is employed. The face becomes glazed in use, and it is claimed that slag and clinker do not adhere to it. As somewhat similar quartz mica schists occur in the Moine Series in Scotland, and possibly in Anglesea, the author suggests that they may be used for the same purpose.—A. B. S.

Electric versus open-hearth [steel] furnace practice. E. H. Ballard. Blast Furnace and Steel Plant, 1920, 8, 62.

A COMPARISON of the cost of electric and open-hearth steel made from actual running costs of a 6-ton Héroult electric furnace and a 20-ton oil-fired open-hearth furnace. As the furnaces were only run for comparison over short periods, in working out the costs certain deductions and allowances were made on the actual costs, in order that the figures presented should permit the best comparison, assuming both furnaces were operating under normal and reasonably full-time conditions. A summary of the costs is as follows:—

	Electric furnace.	Open-hearth furnace.
	Net ton.	Net ton.
	\$	\$
Total metal cost	9.52	14.28
Special metals	1.79	3.52
Expense items	21.58	6.60
Molten metal cost in ladle	36.57	32.55

The steel made was an alloy steel, and the metal made in the electric furnace was superior in chemical and physical requirements to the open-hearth steel.—J. W. D.

Electric furnace smelting; Problems in —. F. Holmgren. Trans. Swedish Iron Inst., 1919. Chem. and Met. Eng., 1920, 22, 165-172.

INVESTIGATIONS have been made on existing furnaces in Sweden in order to determine the best

arrangement of electrodes and leads, and the relation between the electrical and metallurgical behaviour of the furnace. A considerable reduction of the losses in the conductors was effected by connecting the transformer leads to adjacent electrodes, thus reducing the resulting electro-magnetic fields. The heat supply at the different electrodes is often irregular, due to an uneven energy supply or to an unsuitable mixture (excess of coal or ore) surrounding the electrode. The electrodes should be controlled individually to attain regular working of the furnace as a whole. Electric furnaces may be operated with any of the standard frequencies now in use, and the output of a furnace may be increased by increasing the current intake by means of larger or a greater number of electrodes. Too high a voltage is not permissible on account of the reducing action on the silica walls of the furnace. 30-40% of the losses from the transformer to the electrode may be traced to faulty contacts. The shorter the leads, the better will be the operation from the electrical point of view.—C. A. K.

Zinc retorts; Microstructure of —. A. Scott. Trans. Ceram. Soc., 1918-9, 18, 512-515.

AN examination of thin sections of various parts of a used zinc retort showed that the outer yellowish-gray portion consists of sporadic quartz grains in an opaque matrix of calcined clay, which in part is replaced by a clear glass containing innumerable microlites of hexagonal zinc orthosilicate with some sillimanite. As the blue portion of the retort is approached these microlites increase in number, the amount of quartz which has been converted into tridymite also becomes greater, and small isotropic octahedra of zinc spinel appear. In the blue material the alumina and zinc form zinc spinel, whilst the silica appears partly as tridymite and partly as zinc and iron silicates. The grog particles have been attacked externally, but retain an unaltered core. The quartz has been wholly inverted to tridymite, and a concentration of willemite needles often surrounds the latter. Two types of zinc silicate are present: the orthosilicate (willemite) and small quantities of the metasilicate. Some sections show brown crystals of fayalite in which part of the iron has been replaced by zinc. When a mixture of zinc oxide and iron pyrites was allowed to impinge on to a silica brick at 1400° C., a thin section of the brick so treated showed that the effect was confined to the matrix, the coarser fragments being unaltered. The quartz in the matrix was completely inverted to tridymite; the iron pyrites had been oxidised to magnetite, and the zinc oxide had formed prismatic crystals of zinc silicate agreeing with Gaubert's mineral (willemite with 10% of iron oxide). The spinel crystals which form one of the chief constituents of used zinc retorts vary in colour from deep blue to light green, and are identical with gahnite, ZnAl_2O_4 .—A. B. S.

Zinc furnace refractories. J. A. Audley. Trans. Ceram. Soc., 1918-9, 18, 468-477. (See this J., 1918, 702 A.)

FURTHER information based on the work of Brandhorst (this J., 1901, 91), Mühlhauser (this J., 1918, 471 A, 658 A; 1919, 42 A), and others is given. It is suggested that in coating retorts with zirconia a series of coatings, each containing more zirconia than its predecessor, should be employed so as to overcome the lack of adhesion of pure zirconia to the retorts.—A. B. S.

Aluminium dross; Analysis of —. H. Hiller. Z. angew. Chem., 1920, 33, 35-36.

ONE gm. of the finely-divided sample is boiled in a flask with 20 c.c. of water to decompose any carbide which may be present, and the flask is then connected with an apparatus in which the hydrogen liberated when the sample is treated with dilute sul-

phuric acid is passed over heated copper oxide; the water formed is collected in the usual form of calcium chloride tube and weighed. Before the determination is commenced the air is displaced from the whole apparatus by means of a current of carbon dioxide passed previously through sodium carbonate solution. The hydrogen is dried by passing it through sulphuric acid and calcium chloride tubes before it enters the combustion tube: 541 grms. of water is equivalent to 542 grms. of aluminium.—W. P. S.

Potassium anhydrotellurate; Application of the reduction of — by zinc to the treatment of tetradymite and to the estimation of tellurium in this mineral. P. Hulot. *Bull. Soc. Chim.*, 1920, 27, 100—101. (See this J., 1920, 189 A.)

The tetradymite is first treated with dilute hydrochloric acid to remove the calcareous gangue, and the residual material is dissolved in hot, concentrated nitric acid, the solution being subsequently evaporated to dryness. The residue is fused with twice its weight of potassium nitrate. The resulting mass contains potassium sulphate, potassium selenate, bismuth oxide, and potassium anhydrotellurate. The two first-named salts are extracted with boiling water and the bismuth oxide with dilute hydrochloric acid. The residue after washing with dilute hydrochloric acid is suspended in the same acid and zinc is added. The whole of the tellurium is deposited in a pure state and may be filtered off, dried, and weighed after the whole of the zinc has dissolved.—W. G.

Steel; Process of casting —. D. T. Main, Winnipeg, Canada. U.S. Pat. 1,327,398, 6.1.20. Appl., 17.6.18.

BROKEN pieces of high-speed steel are melted in a crucible. 1% of manganese and 0.5% of silicon are added to the molten mass, and the metal is cast in previously prepared moulds.—L. L. L.

Steel ingots; Process for casting —. R. G. Coates, Pasadena, Cal., Assignor to Valley Mould and Iron Corp., New York. U.S. Pat. 1,327,987, 13.1.20. Appl., 20.8.17.

THE steel is poured into shallow moulds and the temperature is then controlled by radiant heat so that the isothermal zone of fusion measured at a mid-transverse cross-section gradually advances inwards and upwards from coincidence with the surfaces of the mould to coincidence with the top surface of the steel mass.—J. W. D.

Iron or steel surfaces; Process of oxidising —. T. Rondelli, Turin, Italy. Eng. Pat. 137,436, 26.3.19. (Appl. 7617/19.)

AN oxide of a metal such as lead, electro-negative to iron, is added to an alkaline bath so as to produce oxidation of the iron or steel surface, with separation of the metal of the oxide, without using an electric current.—J. W. D.

Rust preventing and arresting solution. W. H. Allen, Detroit, Mich. U.S. Pat. 1,329,573, 3.2.20. Appl., 25.9.19.

IRON and steel surfaces are treated with a solution consisting of 25 parts of pure phosphoric acid, 20 parts of glucose, and 45 parts of water.—J. W. D.

Metallurgical reduction process. Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. Eng. Pat. 126,951, 23.4.19. (Appl. 10,131/19.) Int. Conv., 15.5.18.

CARBON dioxide is passed upwards through a shaft furnace containing metal sulphides heated above 600° C. Carbon monoxide and sulphur dioxide are formed, and the ore is converted to oxide. The mixed gases are passed through scrubbers to remove the sulphur dioxide, and the carbon monoxide is then utilised in a second furnace for the reduction of oxide ore. The exhaust gases from the second furnace may be led through a fresh charge of sulphide ore for the re-production of carbon monoxide.—T. St.

Blast furnaces; Heating of air to be supplied to —. Comp. des Forges et Acieries de la Marine et d'Homecourt, Paris. Eng. Pat. 128,582, 19.6.19. (Appl. 15,471/19.) Int. Conv., 20.6.18.

BLAST-FURNACE gas to be burned in a Cowper stove is mixed as it leaves the top of the furnace with a hydrocarburetted gas or mixture of hydrocarburetted gases, or liquid fuels such as tar or oil, with the object of raising the temperature of combustion and accelerating the exchange of heat in the stove.—J. W. D.

Cupolas. W. H. and D. H. Wood, Birmingham. Eng. Pat. 137,399, 2.8.19. (Appl. 2705/19.)

THE tuyères are arranged in two or more horizontal planes with a separate air belt of pressed steel for each set of tuyères in the same plane. The tuyère-boxes have hinged covers operated from outside the cupola, and from the bottom of each box an overflow pipe closed by a fusible plug passes to the outside of the air belt.—J. W. D.

Annealing furnace. L. Wolffgram, Erie, Pa. U.S. Pat. 1,329,873, 3.2.20. Appl., 24.5.18.

THE main heating chamber is surrounded by an outer chamber which extends over the top, back, and bottom of the main chamber. A heating agent is introduced into the upper part of the outer chamber at the front and also into the main chamber at the front. The two streams of hot gas unite in the outer chamber behind the main chamber, and the gas then passes under the main chamber through a controlling device to the stack.—W. F. F.

Ore briquettes; Manufacture of —. H. G. Hills, Bramhall, and E. Wheeler, Cheadle Hulme. Eng. Pat. 137,626, 1.2.19. (Appl. 2566/19.)

FINELY divided iron sand or other ore is mixed with bituminous matter and the mixture subjected to distillation in open shallow trays, during which the bituminous matter is coked and forms a binding material for the ore; the distillation products are recovered. Lime, salt, or manganese may be mixed with the ore so as to modify the by-products or to produce special qualities in the ultimate metal.—J. W. D.

Coating metal upon metal or other conductive flat surfaces for electrotyping for printing work and other like purposes, specially applicable to sound reproducing records and the like. T. R. Harris, Harlington. Eng. Pat. 137,695, 31.3.19. (Appl. 8023/19.)

THE surface to be coated is cleaned and immersed for about five minutes in a solution containing 1 lb. of arsenious acid, 1 lb. of potassium cyanide, $\frac{1}{2}$ lb. of sodium hydroxide, and 1 lb. of acetic acid per gallon of solution. By passing a current of 4 amps. at 4 volts a thin deposit of arsenic is formed, and this is then coated with nickel to a thickness of about 0.002 in. A strengthening layer of copper is applied by electrolytic means and the plate is stripped off. The nickel facing imparts a greater degree of resistance to wear than is obtained with copper shells.—C. A. K.

Liriviating and washing granular or pulverulent ore; Apparatus for —. G. Gröndal, Djursholm, Sweden. Eng. Pat. 137,930, 12.2.19. (Appl. 3464/19.)

VATS with curved bottoms are placed side by side at different levels. A shaft over each vat carries oscillating arms, to which are connected angular feeding and stirring devices. The ore is transported from one vat to the next higher vat, and the solvents or washing agents, which are admitted by several inlets, pass from vat to vat by conduits in an opposite direction to the ore.—J. W. D.

[Aluminium] *solder; Method of making —.* J. Salm, Assignor to C. L. A. Whitney, Albany, N.Y. U.S. Pat. 1,326,971, 6.1.20. Appl., 3.8.18.

A RELATIVELY small quantity of salt is added to melted aluminium, then a relatively large quantity of tin is added, the heat is allowed to decrease, the product covered to prevent oxidation, and zinc in excess of the aluminium and in considerably less quantity than the tin added.—A. de W.

Solder for aluminium. J. Segura, New York. U.S. Pat. 1,328,694, 20.1.20. Appl., 21.10.19.

A SOLDER for aluminium consists of 75–95 parts of lead, 185–205 parts of tin, 185–205 parts of zinc, 5–25 parts of antimony, and 5–25 parts of "white metal" (Sn 80–90, Sb 5–15, and Cu 3–10%).

—C. A. K.

Smelting system; Hermetic unit —. W. McA. Johnson, Hartford, Conn. U.S. Pat. 1,327,282, 6.1.20. Appl., 18.2.15.

AN intermediate readily oxidisable product is prepared by heating the charge and is transferred out of contact with air from the furnace in which it was formed to the actual smelting furnace.—T. St.

Copper alloy; Surface-coloured article of —. Process of surface-colouring articles of copper alloy. T. C. Merriman, Assignor to Winchester Repeating Arms Co., New Haven, Conn. U.S. Pats. 1,327,400 and 1,327,401, 6.1.20. Appl., 5.8.19.

THE articles to be coloured are dipped in an acid oxidising bath and afterwards in an acid solution containing sulphide and an arsenious compound giving a surface finish of black colour.—J. W. D.

Ores; Process for chemical separation of —. A. T. Elliott, Assignor to L. M. Freeman, Los Angeles, Cal. U.S. Pat. 1,327,536, 6.1.20. Appl., 20.2.18.

THE ore is leached with hydrochloric acid and the separated solution treated to obtain a chloride.

This is then decomposed by heat and the chlorine so obtained is utilised in re-producing the leaching solution.—T. St.

[Copper ores;] *Metallurgical process [for the treatment of —]* L. W. E. Greenawalt, Denver, Colo. U.S. Pat. 1,328,666, 20.1.20. Appl., 5.8.18.

COPPER ores are treated with sulphurous acid in the presence of a solution of copper sulphate. Copper is deposited from the mixed solution of copper sulphate and sulphite by electrolysis, and the regenerated sulphuric acid solution is employed to complete the extraction of copper from the treated ore.—C. A. K.

Brass and similar scrap; Method of melting —. Electric furnaces. Method of and means for melting brass and similar scrap. W. R. Clark, Assignor to Bridgeport Brass Co., Bridgeport, Conn. U.S. Pats. (A) 1,328,712, (B) 1,328,713, and (C) 1,328,714, 20.1.20. Appl., (A) 6.5.18, (B) 31.5.18, and (C) 13.6.18.

(A) THE metal is melted in an electric induction furnace having a secondary channel, and the upper surface is heated by independent means to prevent solidification thereof. (B) An electric resistance element is provided in the furnace chamber above the charge to prevent the chilling of the surface of the charge. (C) A preheated side chamber is attached to the melting furnace, which is fed by a slow, continuous advancement of the metal scrap through the preheating chamber.—C. A. K.

Concentrating ores; Method and apparatus for —. J. M. Callow, Salt Lake City, Utah, Assignor to Pneumatic Process Flotation Co., New York. U.S. Pat. 1,329,335, 27.1.20. Appl., 1.1.14.

AN ore mass consisting of metalliferous and non-metalliferous ingredients is formed into a pulp with water. The pulp then flows through a receptacle and forms therein a pulp body of gradually increasing depth. Air under different pressures is delivered to the pulp at different levels, and the rising bubbles of air adhere to and convey the metalliferous particles to the top of the pulp from which they are caused to flow laterally and are collected.

—J. W. D.

Molybdenum; Recovery of — from its ores. H. A. Doerner, Meriden, Conn. U.S. Pat. 1,329,380, 3.2.20. Appl., 14.4.19.

A CURRENT of chlorine gas is passed through molybdenum-containing materials, such as ores and concentrates, maintained at about 500° C., and the resulting gases are treated for the recovery of molybdenum compounds.—J. W. D.

Arc-welding electrode. R. E. Kinkad, Assignor to The Lincoln Electric Co., Cleveland, Ohio. U.S. Pat. 1,329,530, 3.2.20. Appl., 1.11.19.

FINELY divided metallic iron is supplied along the length of the negative iron electrode for the purpose of supplying iron vapour for the maintenance of the arc during the welding operation.—C. A. K.

Furnaces. Eng. Pat. 137,628. See I.

Blast-furnace gas. Eng. Pat. 137,586. See IIa.

Gas for welding. U.S. Pat. 1,329,400. See IIa.

Flake graphite from kish. U.S. Pat. 1,328,845. See VII.

XI.—ELECTRO-CHEMISTRY.

Electrochemical oxidation of benzaldehyde and benzoic acid. Fichter and Uhl. See XX.

PATENTS.

High-frequency coil [for use in melting refractory material]; Artificially cooled —. E. F. Northrup, Princeton, N.J., Assignor to The Ajax Metal Co., Philadelphia, Pa. U.S. Pat. 1,328,336, 20.1.20. Appl., 18.1.19.

In a process for melting refractory material by electric inductive heating the material is enclosed within a coiled conductor, through which a high-frequency current is passed. The conductor is cooled artificially to reduce its resistance, improve its insulation, and permit closer coupling.
—W. E. F. P.

Distillation of coal. Eng. Pat. 137,572. See IIb.

Sulphuric acid. U.S. Pat. 1,328,552. See VII.

Insulating composition. U.S. Pat. 1,329,084. See VIII.

Electric furnace. U.S. Pat. 1,328,713. See X.

Arc-welding electrode. U.S. Pat. 1,329,530. See X.

Extracting oils. U.S. Pat. 1,326,968. See XII.

XII.—FATS; OILS; WAXES.

Olive oil; Adulteration of — [with tea-seed oil]. J. Cofman-Nicoresti. Pharm. J., 1920, 104, 139—140.

Much of the olive oil now on the market is largely adulterated with tea-seed oil. The commercial varieties of this oil sold at the present time include the Chinese product, expressed from the seeds of *Thea sasanqua* (this J., 1908, 451), Assam oil, and Japanese oil (this J., 1908, 948). A similar oil (tsubaki oil) is expressed from the seeds of *Thea japonica* (this J., 1908, 454). All these oils agree closely in physical and chemical characters, the iodine value ranging from 80.1 to 92.7. Four samples of commercial tea-seed oil showed: Sp. gr. 0.9173—0.9198; saponif. value, 179.5—189.4; and iodine value, 81.7—88.92. Tea-seed oil does not give any coloration in Halphen's or the Baudouin test, but on shaking 10 c.c. with 10 c.c. of a mixture of equal parts by weight of strong sulphuric acid, concentrated nitric acid, and water and keeping the tube for 20 mins. in boiling water the oil layer becomes pink. In the case of mixtures of olive oil with less than 20% of tea-seed oil the pink colour is very faint, but by adding 10% of tea-seed oil a coloration may be obtained. A control test with pure olive oil containing 10% of tea-seed oil should give no pink coloration under the same conditions.
—C. A. M.

Gleditschia (black locust) seeds; Oil from and enzymic properties of —. F. Kryz. Oesterr. Chem.-Zeit., 1919, 22, 167—169.

The seeds of the black locust (*Gleditschia triacanthus*, L.) yielded on extraction with ether a viscous yellow neutral oil, which had a faint odour but no taste. The seeds contained a catalase, a peroxidase, and a lipase. On mixing 2 grms. of the finely powdered and sifted seeds with 20 grms. of neutral olive oil and 10 c.c. of neutralised xylene water, and leaving the mixture at 20° C. for four days, the

amount of fatty acids liberated corresponded to 11.0 c.c. of N/2 sodium hydroxide solution. No better results were obtained by adding acid, manganous sulphate, or powdered nickel to the powdered seed, which additions have been found to stimulate the lipolytic activity of castor seed. The lipase of *Gleditschia* seeds is much less active than the castor seed enzyme.—C. A. M.

Oleates and stearates of certain metals. M. d'A. Albuquerque. Revista Chim. pura e appl., 1916, 1. [Reprint.] 8 pages.

The oleates and stearates of certain heavy metals were obtained by precipitating solutions of their salts with alkali oleate and stearate. The absorption spectra and the oxidation by hydrogen peroxide of the ethereal solutions of the metallic soaps were investigated. (See also J. Chem. Soc., 1920, i., 216.)—W. R. S.

Oxidation of paraffin. Kelber. See IIa.

Lipase of germinated barley. Maestrini. See XVIII.

PATENTS.

Oils; Process of extracting — from fatty substances. G. D. Rogers, Gloucester, Mass. U.S. Pat. 1,326,968, 6.1.20. Appl., 7.3.19.

The material is comminuted, mixed with a saline electrolyte, and the mixture passed through and electrolysed in a conduit provided with electrodes of opposite polarity extending longitudinally there-through, the mixture then being passed through a device for effecting separation of the liberated oil.
—A. de W.

Fatty and oily matters; Process for the extraction of — from wet sludges. L. D. Jones, Philadelphia, Pa., Assignor to The Sharples Specialty Co., West Chester, Pa. U.S. Pat. 1,328,047, 13.1.20. Appl., 11.12.18.

The sludge is treated with a solvent to extract the fatty and oily matter, and the resulting mixture, with the aqueous solution, is treated in a centrifugal apparatus to separate the oily solution from the aqueous solution and from the insoluble materials. The insoluble material is floated off.
—W. F. F.

Oils; Process for producing fatty — of low solubility in petroleum spirit. Chem. Fabr. Flörsheim Dr. H. Noerdlinger, Flörsheim. Ger. Pat. 302,113, 6.3.17.

FATTY oils, such as rape, olive, sesamé, and linseed oils are treated first with air, by known methods, and then with steam, preferably superheated, and under pressure if necessary. The treatment with air is carried out at temperatures between 100° C. and that at which spontaneous heating commences. The products are only slightly soluble in petroleum spirit, and, owing to their high viscosity, are suitable for lubricating purposes.—J. H. L.

Glycerin solutions; Process for obtaining concentrated — from dilute, highly impure solutions. K. Löfl, Berlin. Ger. Pat. 314,446, 6.10.18.

The solutions are treated with alcohol or other solvent for glycerol, and frozen. If, for example, a solution containing 3% of glycerol and up to 10% of mineral salts, besides proteins, carbohydrates, etc., is gradually frozen, ice crystals collect at the surface and the impurities are deposited as a precipitate. Methyl or amyl alcohol, acetone, furfural, or epichlorhydrin may be used instead of ethyl alcohol.—J. H. L.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Resinates; Molten metallic —. P. Nicolardot and C. Collignier. Bull. Soc. Chim., 1920, 27, 166—172.

A NUMBER of metallic resinates have been prepared from a sample of colophony by heating it with varying amounts of the corresponding metallic oxides. The apparent acidity, by titration with alcoholic potassium hydroxide, the yield, the amount of the product insoluble in turpentine, and the loss of resin in the process were determined. In all cases 100 grms. of resin was used.

Metallic oxide.		Yield.	Resin lost.	Appa- rent acid value of product.	Amount of product insoluble in turpentine.
Nature.	Weight used.				
	grms.	grms.	%		%
Litharge	20	100	20	65.5	1.80
Litharge	29	119.5	9.5	37.0	2.40
Litharge	31	119.5	11.5	34.2	5.50
Litharge	34	121.5	12.5	28.9	6.70
Quicklime	6	80.5	25.5	47.4	8.80
Slaked lime	7.93	92.5	13.5	60.8	4.30
Slaked lime	12.32	96.0	11.5	29.3	6.40
Manganese dioxide	6.0	90.5	15.5	143.0	4.90
Manganese dioxide	7.5	91.5	16.9	123.4	6.30
Manganese dioxide	8.5	77.0	31.5	101.0	7.10
Cobalt oxide	4.5	87.0	17.5	110.3	22.90
Cobalt oxide	5.5	87.0	18.5	119.6	19.80
Cobalt oxide	6.5	94.5	12.0	118.5	31.50
Cobalt oxide	5.0				
Slaked lime	1.5	84.0	26.0	89.7	9.83
Litharge	10.0				
Manganese dioxide	4.0	103.0	11.0	92.5	4.79
Litharge	9.0				
Manganese dioxide	2.5				
Slaked lime	2.5	97.0	17.9	89.7	1.40

Solubility determinations show that turpentine is the best solvent of these resinates, chloroform and benzene being the next best solvents. The introduction of a small amount of lime materially assists the combination of the other oxides and yields more soluble driers. The loss of resin increases with the temperature to which the mixture of oxide and resin is heated.—W. G.

Antimony trisulphide. De Bacho. See VII.

Colour lakes. Brenner. See XXIII.

PATENTS.

Paints, especially for use as undercoats. W. E. Wright, Bay Village, Ohio, U.S.A. Eng. Pat. 137,475, 5.6.19. (Appl. 14,346/19.)

A READY-MIXED paint consists of lead and/or zinc pigments 100 parts, tung oil 4—14 parts, an oil adapted to retard drying of the tung oil (preferably soya bean oil) 7—35 parts, a drying oil other than tung oil (preferably linseed oil) 5—15 parts, and a volatile thinner 18—24 parts. The use of soya bean oil to retard drying of tung oil is specifically claimed. The pigment is ground in the drying oil other than tung oil, one-half of the thinner is added, and then the mixed tung oil and retarder (soya bean oil) before adding the remainder of the thinner.—A. de W.

Paint oils suitable for cement and concrete; Manufacture of —. F. Boehm, Ltd., and C. A. Reihl, London. Eng. Pat. 137,578, 10.12.18. (Appl. 20,513/18.)

VEGETABLE or animal oil is polymerised to produce a solid, elastic mass which is dissolved in epichlorohydrin, dichlorohydrin, tetrachloroethane, or penta-

chloroethane. A metal linoleate is added to the solution, which is then thinned with turpentine or turpentine substitute. Examples are given in which cotton seed oil and a mixture of soya bean and linseed oils are employed.—W. E. F. P.

Painted or varnished articles; Apparatus for and art of treating [drying] —. C. M. Cumliffe, Assignor to American Blower Co., Detroit, Mich. U.S. Pats. (a) 1,327,313 and (b) 1,327,314, 6.1.20. Appl., 27.12.16.

(A) A DRYING chamber has an air inlet near the top, and means for deflecting the air horizontally so that it will settle down "in mass formation" upon the article within the container. The top wall of the container is spaced vertically from the article to be treated, and the space below the deflector is unobstructed, so that the air meets the article after losing substantially all its velocity. (b) Varnished articles are dried in the lower portion of a chamber as described under (A).—A. de W.

Shellac surrogate and process of producing same. J. R. Köhler, Stockholm. U.S. Pat. 1,327,332, 6.1.20. Appl., 22.4.18.

AMORPHOUS resin acids separated from the natural resin of conifers are combined with glycerin to form a shellac substitute. (See also Eng. Pat. 120,729 of 1918; this J., 1919, 428 A.)—A. de W.

Resinous substances of vegetable origin suitable for impregnating substitutes for textile fibres; Process for preparing —. C. S. Fuchs, Heppenheim. Ger. Pat. 314,418, 14.2.18.

LIGNIC acids obtained by alkaline treatment of vegetable materials are converted into resin-like substances by the action of oxidising agents, e.g., chlorine. The products obtained by the action of halogens on the lignic acids derived from straw are readily soluble in acetone, amyl acetate, and "Propol" (Bayer), and form a hard, tenacious, lustrous surface after evaporation of the solvent. —J. H. L.

Resin-soap produced by heating comminuted wood with sodium carbonate; Process for purifying —. A. Lange, Tomaszow, Poland. Ger. Pat. 314,415, 30.4.18.

THE alkaline liquor obtained by heating comminuted wood with sodium carbonate deposits on cooling a sludge containing resin soap and lignin. This is separated from the supernatant liquor and warmed with sodium hydroxide, whereupon the soap forms large flocks, which are collected and treated with a small quantity of sodium peroxide to oxidise any lignin still present. The liquor containing dissolved lignin is evaporated to recover the excess of soda by crystallisation, and may then be used as a binding agent in the manufacture of briquettes.—J. H. L.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Rubber-like masses; Process for producing soft and hard —. H. Otto Traun's Forschungslaboratorium, G.m.b.H., Hamburg. Ger. Pat. 314,560, 25.2.15.

OILS are mixed with fatty acids in emulsifying (homogenising) apparatus and treated meanwhile with sulphur chloride alone or together with neutral organic liquids. After the reaction is complete the product is washed, neutralised, and heated with or without addition of a filling material. Hard or soft products may thus be prepared from linseed oil, oleic acid, and 10 rubber solution.—J. H. L.

Rubber- or leather-like masses from yeast and formaldehyde; Manufacture of —. H. Blücher, Leipzig-Gohlis, and E. Krause, Berlin-Steglitz. Ger. Pat. 314,728, 20.11.15. (See also Ger. Pat. 280,597; this J., 1916. 430.)

THE materials, consisting of yeast and formaldehyde, with or without the addition of proteins, phenols, oils or glycerin, are mixed with glue in such quantity that the pressed articles remain soft and flexible after cooling. The plastic masses are pressed up with textile fibres or fabrics or with metal parts. The properties of the finished product, especially its hardness, depend principally on the pressure employed. The higher the pressure the more nearly the product approaches in its physical properties to leather. The lower the pressure the more nearly it resembles rubber. If very little or no moulding pressure be employed, soft elastic articles are obtained which have a consistence similar to that of pure Para rubber.

—J. F. B.

Gas for balloons. Ger. Pat. 303,966. See Ha.

XV.—LEATHER; BONE; HORN; GLUE.

Mimosa bark and [tanning] extract; Sugars in —. A. Harvey. J. Soc. Leather Trades' Chem., 1920, 4, 11—13.

FOUR samples of Natal mimosa bark contained 1.5–2.9% of disaccharides and 1.6–1.9% of monosaccharides, which is greater than the sugar content of any other tanning material except pine bark extract. The total amount of sugar in mimosa extracts appears to increase with increasing extraction pressure. Probably hydrolysis of disaccharides to monosaccharides takes place during the manufacture of the extracts, especially when high pressures are employed. Pure unadulterated mimosa extracts yielded 2.2–4.4% of monosaccharides and 3.2–7.2% of disaccharides. The Customs authorities levied duty on extracts containing 4% of disaccharides.—D. W.

Sulphite cellulose; Detection of — in tanning extracts. G. E. Knowles. J. Soc. Leather Trades' Chem., 1920, 4, 13—15.

PURE solubilised quebracho extracts give precipitates with hydrochloric acid, but not with organic acids. Formic acid has been substituted for hydrochloric acid in a modified form of the Procter-Hirst test, and has proved more satisfactory. A positive test with this modified procedure does not necessarily indicate sulphite-cellulose, as synthetic tannins give a similar precipitate.—D. W.

[Tannery] lime liquors; Analysis of —. F. C. Thompson and W. R. Atkin. J. Soc. Leather Trades' Chem., 1920, 4, 15—17.

THE precipitates obtained by neutralising lime liquors with acids or by adding excess of acid have hitherto been assumed to be due to dissolved hide substance. The authors, however, have shown them to be due entirely to dissolved keratinous matter derived from the hair and epidermis, and not to dissolved hide substance. About one-half of the dissolved keratinous matter is precipitated. Solutions obtained by treating gelatin and hide powder with lime, or lime and sodium sulphide, did not give any precipitate on neutralising or adding excess of acid.—D. W.

PATENTS.

Cellulose derivatives; Material [leather etc.] treated with —. J. J. Byers, Brookline, Assignor to Products Syndicate, Inc., Boston, Mass. U.S. Pat. 1,327,197, 6.1.20. Appl., 10.1.17.

LEATHER or other fibrous material, after drying,

is impregnated throughout with a cement which includes soluble nitrocellulose and a non-oxidising oil.—L. L. L.

Strings made from animal tendons and products made therefrom; Process for increasing the elasticity of —. H. Grätzer, Vienna. Ger. Pat. 305,196, 22.10.15. Int. Conv., 29.9.15.

THE threads of other products are drawn through hot water or treated with steam, whereby their elasticity is increased, and the increase is rendered permanent by a further treatment with glycerin. The process may be preceded by a preliminary tanning of the material, but a complete tannage is to be avoided if the elasticity is to be maintained by treatment with glycerin. By tanning the material completely it contracts extensively, acquiring a compact structure and great mechanical strength, exceeding in this respect even leather.

—H. J. H.

Leather-like masses. Ger. Pat. 314,728. See XIV.

XVI.—SOILS; FERTILISERS.

Clay; Coagulation of — and the protective effect of humic acid. S. Odén. J. Landw., 1919, 67, 177—208.

EXPERIMENTS were made with suspensions of two clays of different character, purified by dialysis, and diluted with conductivity water to about 1% concentration. Varying amounts of colloidal humic acid were added to 10 c.c. of each suspension and the effect on coagulation noted. The minimum amount of humic acid required to produce a protective effect on the addition of ammonium nitrate solution as coagulant was 0.065 mgrm. in one case and 0.14 mgrm. in the other. Much larger amounts of humic acid were required to prevent coagulation with barium nitrate and cesium chloride. The with ammonium nitrate and lithium chloride. The protective effect of humic acid appears to be of the same order as that of other colloids, but is greatly influenced by the concentration of the electrolytes present. The effect appears to be specific in character for different clays and electrolytes.

—J. H. J.

Field experiments; Relation between the size of plots and the errors of single observations in —. H. Vageler. J. Landw., 1919, 67, 97—108.

AN experiment was made with 128 field plots each of rye, oats, potatoes, and kale, the size of the plots being 25 sq. m. in the case of rye and oats, 7.5 sq. m. in the case of potatoes, and 5 sq. m. in the case of kale. The crops obtained on each plot were weighed. Various methods of calculating the mean value and the experimental error were worked out, and it is shown that the deductions to be drawn vary according to the method of computation employed.—J. H. J.

Crop production; An experience in —. W. H. Jordan and G. W. Churchill. New York Agric. Exp. Stat., Bull. 465, June, 1919, 1—20.

AN experiment in crop production is described in which crops of corn (maize), oats, wheat, and grass, clover and timothy, have been grown in a 4-year rotation for 16 years. The fertilisers used were farmyard manure, a complete fertiliser, and an acid phosphate (superphosphate) with a minimum amount of nitrogen, while two plots received no fertiliser. The largest crop was given by the farmyard manure, closely followed by the complete fertiliser; these two plots gave a 56% increase (dry weight) over the plots without fertiliser. The plot with the incomplete fertiliser gave a 33% increase over the unmanured plots. The grass plots growing

clover gave a larger yield of dry matter than those growing timothy grass, although the timothy maintained as good yields as the clover on the unmanured plots. Analyses of the soil were made, but no relation was found between the results of a soil analysis and the fertility. The cheapest fertiliser as regards crop value was superphosphate with a trace of sodium nitrate added.—J. H. A.

Nitrification of barnyard manure-nitrogen in arable soil; Influence of time on the —. C. Barthel and N. Bengtsson. *Soil Sci.*, 1919, 8, 243—258.

THE addition of calcium carbonate to neutral or acid cultivated soils does not cause any favourable influence on the nitrification of the nitrogen in applied farmyard manure, but, on the contrary, where excessive dressings (equivalent to 2% of calcium oxide) were applied an impeding effect was noticed. The authors have examined various methods for the estimation of ammonia-nitrogen in soils, and conclude that none of them permits of an accurate quantitative extraction of ammonia from any and every soil. Boussingault's method by direct distillation with magnesium oxide is probably the most satisfactory.—W. G.

Guano from Sardinia. M. Gina. *Gazz. Chim. Ital.*, 1919, 49, II., 246—249.

THE occurrence of veins of tricalcium phosphate, resembling ordinary phosphorite, in the bat guano from the Borutta grotto at Sassari, Sardinia, is regarded as confirmation of the view that many phosphatic deposits owe their origin to deposits of guano. (See also *J. Chem. Soc.*, 1920, i., 276.) —T. H. P.

Moisture in solid substrata; Relation of — to physiological salt balance for plants and to the relative plant-producing value of various salt proportions. J. W. Shive. *J. Agric. Res.*, 1920, 18, 357—378.

IN sand cultures varying the moisture content from 40 to 80% had no effect on the optimum physiological balance of the nutrient solutions for production. Good physiological balance and optimum total concentration of a nutrient solution are not the only factors, as the actual plant-producing value of any fertiliser treatment is largely determined by the moisture conditions of the substratum. The highest yields of tops and roots and high transpiration rates were obtained with a moisture content of 60%.—W. G.

Lime; Effect of — upon the sodium chloride tolerance of wheat seedlings. J. A. Le Clerc and J. F. Breazeale. *J. Agric. Res.*, 1920, 18, 347—356.

VERY small amounts of calcium oxide or sulphate overcame the toxic effects of sodium chloride or sodium sulphate. Magnesium sulphate and barium chloride were slightly antagonistic to sodium chloride. Potassium chloride, sodium nitrate, sodium phosphate, ferric chloride, and alum had no effect on the toxicity of sodium chloride. (See further *J. Chem. Soc.*, Apr., 1920.)—W. G.

Cereal seeds; Treatment of — by dry heat. D. Atanasoff and A. G. Johnson. *J. Agric. Res.*, 1920, 18, 379—390.

BARLEY, wheat, rye, and oat seeds, especially when of good quality and well-dried, are able to withstand exposure to dry heat at 100° C. for thirty hours. Seed infections from bacterial blight of barley (*B. translucens*) and the bacterial blight of oats (*Pseudomonas arena*) may be both eliminated by this treatment. A number of seed-borne fungoid diseases such as wheat scab (*Gibberella saubinetii* and *Fusarium* spp.), primary infections only, and spot-blotch of barley (*Helminthosporium sativum*)

are practically eliminated by this dry heat treatment, and other diseases such as net-blotch (*H. teres*), stripe disease (*H. gramineum*) of barley, and *Helminthosporium* blotch of oats (*H. avenae-sativae*), as well as loose smut of barley and smuts of oats, are also markedly reduced without materially injuring the germination of the seed. —W. G.

Plant juices; Factors affecting the acidity or hydrogen-ion concentration of —. C. B. Clevenger. *Soil Sci.*, 1919, 8, 227—242.

CERTAIN factors must be taken into account in determining the hydrogen-ion concentration of plant juices (see page 249 A). The expressed juice usually becomes more acid on standing, while plants when cut and allowed to stand some time before the juice is expressed usually become more alkaline. Further, the acidities of the leaves, stems, and roots show marked variations over a 24-hour period. The acidity of the leaves and stems is highest in the morning and decreases during the day, while the acidity of the roots is highest during the day. The acidity of the soil also influences the acidity of the different parts of plants grown on the soil. Oats, buckwheat, soya beans, and cow peas were grown on acid soils and on the same soils after liming, and it was found that, with the exception of buckwheat, the tops of the plants grown on the limed soil were usually more acid than those grown on the unlimed soil. The acidity of the roots of the plants appeared to be correlated with that of the soil. The type of fertiliser also appears to have some influence on the acidity of the plants, as is roughly indicated by comparative trials with sodium nitrate and ammonium nitrate.—W. G.

Bacteria. Conn and Breed. See XIXB.

PATENT.

Ammonium nitrate fertilisers. Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. Eng. Pat. 129,974, 25.6.19. (Appl. 16,021/19.) Int. Conv., 19.7.18. (See also Eng. Pat. 117,823; this J., 1918, 556 A.)

AN easily decomposable phosphate is finely ground and 1 part of the powdered substance is mixed with 2—10 parts of ammonium nitrate. The mixture is moistened with water, and is then heated with continuous stirring until it becomes granular. —J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

[*Sugar cane milling; Colloidal water, apparent and real imbibition, and the coefficient of mixing* [in —]. C. Müller. *Bull. Assoc. Chim. Sucri.*, 1919, 37, 118—121.

THE fact that successive crushings of sugar cane yield juices of decreasing sugar-content and that the juice remaining in the bagasse is poorer in sugar than the last mill juice, has been attributed to the presence, in cane, of "colloidal water" held by certain constituents and distinct from the saccharine juice. Methods of calculating the proportion of "colloidal water," the imbibition, i.e., the degree of dilution of the extracted juice corresponding to the use of a given quantity of maceration water, and the "coefficient of mixing," i.e., the sugar: water ratio in the last mill juice, expressed as a percentage of the sugar: water ratio in the final bagasse, are illustrated by examples. The "coefficient of mixing" indicates the efficiency of maceration. It may be as low as 43 when excessive amounts of maceration water are used, e.g.,

35—36 of the weight of the cane, whilst coefficients of 68—70 may be obtained by well-conducted maceration with only 18—20% of maceration water (referred to cane), and without any diminution in the yield of sugar extracted.—J. H. L.

New hydrazones of some monosaccharides [*m*-tolylhydrazones of *l*-arabinose, rhamnose, fucose, *d*-galactose, and *d*-mannose]. A. W. van der Haar. Rec. Trav. Chim., 1920, 39, 191—193.

With *m*-tolylhydrazine, arabinose, rhamnose, fucose, and *d*-galactose gave well-defined hydrazones; *d*-mannose gave an amorphous hydrazone; the hydrazone from dextrose could not be obtained pure and xylose and levulose gave negative results. (See further J. Chem. Soc., Apr., 1920.)—W. G.

Inversion of sucrose. André. See XIXa.

Liquefaction of starch. Bettinger. See XVIII.

Inulin in artichoke tubers. Colin. See XIXa.

XVIII.—FERMENTATION INDUSTRIES.

Starch; Determination of the value of different acids for the liquefaction of —. P. Bettinger. Bull. Assoc. Chim. Sucr., 1919, 37, 126—131.

In distilleries which employ Mucors as saccharifying agents, raw cereal mashers are commonly cooked under pressure in presence of a small quantity of hydrochloric acid to effect liquefaction of the starch. Experiments described indicate that in order to produce satisfactory liquefaction in mashers containing 1000 kilos. of ground cereal and 40 hectolitres of water, by heating at 120° C. for 30 mins., the following quantities of ordinary commercial hydrochloric acid must be added:—12 litres for rice mashers, 14 litres for maize, manioc, or millet mashers, and 16 for barley mashers. Chemically equivalent amounts of sulphuric acid produce less complete liquefaction under similar conditions, whilst oxalic, tartaric, and acetic acids act much more feebly in the order given. A part of the added acid is neutralised by alkaline constituents of the mash, and a further part (in the case of mineral acids) is replaced by weaker acids displaced from their salts. If allowance is made for these factors the liquefying activities of the various acids may be accounted for by their relative degrees of ionisation.—J. H. L.

Enzymes. I. Amylase of germinated barley. D. Maestrini. Atti R. Accad. Lincei, 1919, 28, II., 393—394.

THE amylase of germinated barley may be extracted by means of distilled water, but a more active extract is obtained if the water contains 0.003 mol. % of acetic acid; if a highly-active solution is required the extraction should occupy at least 6 hours. By this extract commercial soluble starch is highly degraded, even in a neutral medium, but barley, potato, or maize starch is not converted unless first gelatinised and unless the medium has a certain acidity, namely, 0.003 mol. % of acetic acid. The nature of the starch is without appreciable influence on the amylolytic activity. Hydrochloric and acetic acids activate the amylolytic decomposition to similar degrees. Potassium hydroxide in the concentration 0.003 mol. % paralyses the amylolytic activity in 10 hours. The yield of reducing sugar resulting from the action of the amylase has its maximum value at about 45° C., and diminishes to zero at about 70° C.—T. H. P.

Enzymes. II. Protease and lipase of germinated barley. D. Maestrini. Atti R. Accad. Lincei, 1919, 28, II., 456—458.

THE protease of germinated barley cannot be extracted by water. If distilled water is used, the barley-water emulsion shows no proteolytic activity, but the latter becomes marked if the water contains 0.003 mol. % of acetic acid. If very high enzymic activity is desired, the contact of the meal with the acidified water must occupy at least 6 hours at 20°—30° C. If the emulsion is rendered neutral towards litmus by means of potassium hydroxide and then acidified with hydrochloric acid to the extent of 0.003 mol. %, its proteolytic activity is diminished; the activity is also greatly lowered if 0.003 mol. % of potassium hydroxide is dissolved in the neutralised emulsion. The enzyme acts best at 45°—50° C., and is destroyed at 52°—55° C. Germinated barley contains also a lipolytic enzyme, the presence of which is demonstrable only in the emulsion and not in the filtrate. Emulsions prepared with distilled water exhibit only very feeble lipolytic activity, whereas those made with 0.003 mol. % acetic acid solution are highly active. When treated with this enzyme for 48 hours at 31°—40° C. sweet almond oil shows an acid value, expressed in mgrms. of potassium hydroxide, somewhat greater than 3 and an ester value which falls to 150. At the concentration 0.003 mol. % hydrochloric acid weakens the action of the lipase. The optimal temperature is about 45° C., and the temperature at which the enzyme is destroyed about 55° C.

T. H. P.

Glycerophosphatase of seeds. A. Nemeš. Bull. Soc. Chim., 1920, 27, 153—158.

It has been shown (Biochem.-Zeits., 1919, 93, 94) that glycerophosphatase is very widespread in plant cells and in the tissues of ungerminated seeds. The author finds that this enzyme acts best in a medium having an acidity equal to 0.06N, and that the reaction is bimolecular.—W. G.

Yeast cells; Behaviour of certain dyes towards —. H. von Euler and N. Florell. Arkiv Kem. Min. Geol., 1918—1919, 7, No. 18, 1—27.

DYES are absorbed by yeast in two ways. Some dyes penetrate the cell and are retained therein, others are adsorbed on the surface of the cell. In the former case the cell shows the stain under the microscope; in the latter the stain can only be detected in reflected light. The surface adsorption is the more common phenomenon of the two, and is controlled to a large degree by the previous preparation, especially washing, of the yeast. The absorption in both cases is influenced by such factors as the concentration of the dye, temperature, hydrogen ion concentration, and the presence of a fermentable sugar in the solution. The staining of the yeast with Chrysoidine (diaminoazobenzene hydrochloride), Janus Blue (safraninazo- β -naphthol hydrochloride), Ponceau 3R (sodium salt of cumidineazonaphtholdisulphonic acid), and Methylene Blue impairs its fermenting capacity.—S. S. Z.

Invertase and fermentation enzymes in a top yeast. H. von Euler and E. Moberg. Arkiv Kem. Min. Geol., 1918—1919, 7, No. 12, 1—17.

THE production and the activity of the invertase of a top yeast was only influenced to a small extent by a protoplasmic poison such as chloroform. In the top yeast investigated it was not possible to augment the invertase by Euler's method to the extent previously done in bottom yeasts. Comparative experiments showed that on drying practically the entire invertase content was retained by the dried yeast. The amount of alcohol and carbon dioxide produced from a certain quantity of sugar

in alkaline solution by dried and fresh yeast was approximately the same, and was not influenced by the addition of co-enzyme. The co-enzyme previously heated with sodium hydroxide became, however, more active. The author concludes that besides the co-enzyme and phosphate, fermentation in alkaline solution requires another activator, most probably of the nature of an alkali salt.—S. S. Z.

Yeast; Growth of — in alkaline solutions. Chemical enzyme studies. H. von Euler and O. Svanberg. Arkiv. Kem. Min. Geol., 1918–1919, 7, No. 11, 1–13.

THE maximum alkalinity of the medium in which a Frobberg bottom yeast grew was between p_H 7.7 and p_H 8. A distillery top yeast (S.B. II.) showed decided growth at p_H 7.3. The maximum, however, tolerated by growing yeast depends to a great extent on the quantity of cells seeded. The maximum alkalinity for *Saccharomyces ellipsoideus* and *Pseudosaccharomyces apiculatus* was p_H 7.9 and p_H 7.6 respectively. The highest limit of alkalinity tolerated by *Aspergillus niger* was found to be p_H 9.—S. S. Z.

Methyl and ethyl alcohols; Differentiation of —. T. Sabalitschka. Pharm. Zentr., 1920, 61, 78–79.

THE author agrees with Pannwitz (this J., 1920, 38A) that the copper sulphate test is useless in the presence of water. The test may, however, be of some use for the detection of methyl alcohol in absolute alcohol.—W. P. S.

XIXA.—FOODS.

Mixed meats, sausages, etc.; Determination of added water in —. R. Leclercq. Ann. Valsil., 1919, 12, 356–367.

ACCORDING to French law sausages and similar products must not contain more than 75% of water (calculated on the fat-free substance); in the case of smoked products the maximum limit for water is 85%. Since 81% of water has been found to be present in meats, the author considers that the limit of 75% is too low, and that, in any case, the quantity of water in meats varies so widely that results of analysis may lead to erroneous conclusions as to the presence of added water.

—W. P. S.

Potatoes; Manufacture of so-called compressed —. G. Wiegner and H. Mehlhorn. J. Landw., 1919, 67, 151–170.

COMPRESSED potatoes are prepared by pressing out the greater part of the water from fresh potatoes and then drying the product. 100 kilos. of fresh potatoes after pressing yields 22.5 kilos. of compressed potatoes containing 12% of moisture. The product has a starch value of 71%, and contains 15% of crude protein or 0.08% of pure albumin. By direct drying, without compression, 100 kilos. of fresh potatoes yields 25.2 kilos. of product with 12% of moisture. This product has a starch value of 69%, and contains 6% of crude protein or 2.3% of pure albumin. Detailed analyses of the chemical composition of compressed potatoes are given.

—J. H. J.

Fat-soluble vitamins. Comparative nutritive value of white and yellow maize. H. Steenbock and P. W. Boutwell. J. Biol. Chem., 1920, 41, 81–96.

THE occurrence of yellow pigment and the growth-promoting property attributed to the presence of the fat-soluble vitamins seem to be intimately associated in the maize kernel.—J. C. D.

Inulin in artichoke tubers; Origin and transformation of —. H. Colin. Bull. Assoc. Chim. Sucri., 1919, 37, 121–126.

IN the Jerusalem artichoke (*Helianthus tuberosus*) the formation of inulin takes place in the stem and is completed in the tubers, the raw material consisting mainly of dextro-rotatory carbohydrates supplied by the leaves. The inulin-content of the tubers remains practically constant from August to November, but afterwards diminishes. (See also J. Chem. Soc., Apr., 1920.)—J. H. L.

Sucrose in orange juice; Inversion of —. G. André. Comptes rend., 1920, 170, 292–295. (See this J., 1920, 201A.)

THE hydrolysing action of the citric acid present in orange juice on the sucrose also present is very marked at the ordinary temperature. The action of the invertase present is also marked, but much less intense than that of the citric acid.—W. G.

Plant juices. Clevenger. See XVI. and XXIII.

Indole. Zoller. See XXIII.

PATENTS.

Bread, cakes, and the like; Manufacture of —. W. H. Stephenson, Rock Ferry, Cheshire. Eng. Pat. 137,365. (Appls. 132, 7.1.19 and 13,820, 31.5.19.)

DORTON for bread making is improved by adding to the flour a mixture of one part of ammonium chloride and 5–7 parts of ammonium sulphate, in the proportion of 1 oz. to the sack. If the flour is

made from a hard wheat, a mixture of 1 part of ammonium sulphate to 4 parts of chloride is used.
—J. H. J.

Food; Process of treating —. A. Babendreer, Ocean Springs, Miss., Assignor to Whole Grain Wheat Co., Phenix, Ariz. U.S. Pat. 1,327,220, 6.1.20. Appl., 17.9.17.

A CLOSED receptacle is filled with matured grain and liquid, and is heated with continuous movement until the grain is cooked. The volume of liquid used is adjusted so that at the completion of the process the grain almost completely fills the receptacle.—J. H. J.

Milk; Process of treating —. H. Buel, Seattle, Wash. U.S. Pat. 1,327,308, 6.1.20. Appl., 3.4.16.

A CULTURE of lactic acid bacteria is added to sterilised milk, and the milk is incubated until a bacterial count shows the desired number of organisms per c.c., and until a sufficient degree of acidity is produced to restore to the milk its flavour and digestibility. The milk is then maintained under the conditions obtaining for new milk.—J. H. J.

Yeast for fodder; Production of —. Verein der Spiritus-Fabrikanten in Deutschland, Berlin. Ger. Pat. 299,649, 2.4.15.

YEAST is grown, by the aeration process, in suitably acidified liquids containing sugar and human or animal urine, to which may be added mineral salts to supply phosphoric acid, lime, etc. The nitrogen of urine is directly assimilable by yeast (cp. Bokorny, this J., 1917, 1284), but if necessary it may first be converted into ammonium carbonate by a preliminary bacterial fermentation. In place of sugar, molasses or products such as brewers' grains, distillers' wash, or waste from starch factories may be used after saccharification with sulphuric acid.—J. H. L.

Drying apparatus. Eng. Pat. 123,984. See I.

Cellulose from peat etc. Ger. Pat. 314,712. See V.

XIXB.—WATER PURIFICATION; SANITATION.

Bacteria; Use of the nitrate-reduction test in characterising —. H. J. Conn and R. S. Breed. New York Agric. Exp. Stat., Tech. Bull. 73, June, 1919. 21 pages.

THE value of the reduction of nitrate-broth test was investigated with the colon group of bacilli. It was found that at least 0.5% of peptone must be present in the medium to ensure vigorous growth. Under these circumstances all members of the group rapidly reduced nitrate to nitrite. With *B. cereus* some strains were found which constantly failed to act on nitrates, while others were inconsistent. *B. fluorescens* required to be in vigorous growth before reducing nitrates consistently, and also no other source of nitrogen must be present. *B. caudatus* reduced nitrate to nitrite, which was converted into ammonia as fast as produced. The general conclusion is drawn that the test can only be done on media free from other sources of nitrogen, and that it is too liable to variation to make it useful for routine work.—J. H. J.

PATENT.

Fatty matter from wet sludges. U.S. Pat. 1,328,917. See XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Yeast nucleic acid; Structure of —. P. A. Levene. J. Biol. Chem., 1920, 41, 19–23.

THE preparation of crystalline cytidinephosphoric acid is described. The mononucleotides tend to form mixed crystals which may, on analysis, be mistaken for polynucleotides. (See further J. Chem. Soc., 1920, i., 259.)—J. C. D.

Indole; Influence of hydrogen ion concentration upon the volatility of — from aqueous solution. H. F. Zoller. J. Biol. Chem., 1920, 41, 37–44.

THE most rapid volatilisation of indole from aqueous solutions occurs when the solution possesses a hydrogen ion concentration of from $p_H=8.0$ to $p_H=10.5$.—J. C. D.

Salvarsan and neosalvarsan; Detection of arsenic in —. Utz. Pharm. Zentr., 1920, 61, 39–42.

ABOUT 0.05 grm. of the sample is dissolved by warming with 15 drops of concentrated sulphuric acid and a few crystals of ammonium persulphate are added from time to time until the mixture remains colourless; the solution is then diluted with a small quantity of water and 1 c.c. of stannous chloride solution is added. The solution soon becomes yellow in colour and later the arsenic forms a brown flocculent precipitate. The organic matter may also be destroyed by heating the sample with concentrated hydrogen peroxide solution and a small quantity of ferrous sulphate before the arsenic is detected by means of the stannous chloride test. Another test consists in treating a portion of the substance with hydrochloric acid in a platinum basin and adding a fragment of zinc; a brown stain appears on the platinum. If a small quantity of salvarsan or neosalvarsan is dissolved in water, treated with concentrated sodium thiosulphate solution, and the mixture acidified with hydrochloric acid, a white turbidity appears almost at once, and this, after a time, is coloured bright yellow owing to the formation of arsenic sulphide. The latter may be collected and identified by the usual tests.—W. P. S.

Benzaldehyde and benzoic acid; Electrochemical oxidation of —. F. Fichter and E. Uhl. Helv. Chim. Acta, 1920, 3, 22–39.

THE electrochemical oxidation of these substances at platinum anodes has been studied with particular reference to the products formed in minor quantity. Toluene is converted successively into benzyl alcohol and benzaldehyde; the latter is transformed into dibenzylidene peroxide hydrate.

$C_6H_5CH(OH).O_2.(HO)CH.C_6H_5$, which converts unchanged benzaldehyde into benzoic acid. A portion of the latter yields quinol, another part gives successively salicylic acid, 2,5-dihydroxybenzoic acid, and 2,4,5-trihydroxybenzoic acid, whilst a third portion gives rise to *p*-hydroxybenzoic acid, which yields quinone on the one hand and 3,4-dihydroxybenzoic acid and 2,4,5-trihydroxybenzoic acid on the other hand. These products are also susceptible to further oxidation. (See also J. Chem. Soc., 1920, i., 234.)—H. W.

Furfural; Catalytic reduction of —. H. Pringsheim and H. Noth. Ber., 1920, 53, [B], 114–118.

THE reduction of furfural by Sabatier's method appears to follow three courses concurrently: (i.) reduction of the aldehyde group as far as methyl; (ii.) elimination of the aldehyde group with the formation of furan, and hydrogenation of the ring in both cases (i) and (ii.); (iii.) rupture of the ring and formation of pentan- β -ol and methyl propyl ketone.—J. C. W.

Ethers; Catalytic preparation of — by the dry way. A. Mailhe and F. de Godon. Bull. Soc. Chim., 1920, 27, 121—126.

THE method previously described (this J., 1919, 9624) for the preparation of ether from alcohol, calcined alum being the catalyst, has been successfully used for the preparation of a number of simple and mixed aliphatic ethers from the corresponding alcohols, up to isoamyl alcohol. Isopropyl and isobutyl alcohols only gave very small yields of the corresponding ethers.—W. G.

Aldehydes and ketones; General method of preparation of —. Dehydrogenation of primary and secondary alcohols by catalytic oxidation. C. Moureu and G. Mignone. Comptes rend., 1920, 170, 258—261.

FINELY divided silver, deposited on asbestos by precipitation from silver nitrate with formaldehyde, is an excellent catalyst for the oxidation of primary and secondary alcohols to aldehydes and ketones respectively. The vapour of the alcohol mixed with slightly less than the theoretical amount of air is passed over the catalyst at 230°—300° C. In some cases the action is so intense as to result in very marked local rise in temperature of the catalyst, with consequent destruction of some of the products of oxidation. In this case it is better to conduct the operation in two stages, first passing the alcohol vapour mixed with half the requisite volume of air over the catalyst, and then mixing the issuing vapours with the rest of the air and passing them over a second lot of the catalyst. Yields varying from 60—96% of theory were obtained from methyl, ethyl, butyl, amyl, allyl, benzyl, cinnamyl, isopropyl, and secondary butyl alcohols by this method.—W. G.

Iron filings for pharmaceutical use; Analysis of — H. Hindley. Pharm. J., 1920, 104, 117.

DETERMINATION of the iron in iron filings by the official B.P. method for *ferrum reductum*, in which the iron is made to react with copper sulphate and the resulting ferrous sulphate titrated with potassium permanganate solution, gives concordant and high results. This appears to be due to the presence or formation of hydrogen, which reacts with the phosphorus in the iron to form hydrogen phosphide. By prolonged boiling, however, the hydrogen phosphide is eliminated and accurate results are obtained.—C. A. M.

Reactions of calcium hydride. Reich and Serpek. See VII.

PATENTS.

Esters of ethylenic halogenhydrins; Manufacture of —. Soc. Chim. des Usines du Rhône, Paris. Eng. Pat. 128,911, 7.6.19. (Appl. 14,519/19.) Int. Conv., 26.6.18.

ETHYLENIC halogenhydrin esters of the general formula $R\cdot COOCH_2\cdot CH_2\cdot X$, where R is an alkyl or aryl group, and X a halogen, are prepared by the interaction of ethylene oxide and an acidyl halide in equi-molecular proportions, at a suitable temperature depending on the particular acid chloride or bromide used. The reaction, which is extremely regular and gives quantitative yields, is conveniently brought about by passing gaseous ethylene oxide through the acidyl halide at atmospheric pressure. Examples are given of the preparation of β -chloroethyl acetate from acetyl chloride at its boiling-point, β -chloroethyl chloroacetate from chloroacetyl chloride at 100° C., β -chloroethyl benzoate from benzoyl chloride at 190°—240° C., β -chloroethyl *p*-nitrobenzoate from *p*-nitrobenzoyl chloride at 190°—240° C., and

β -bromoethyl acetate from equimolecular proportions of acetyl bromide and ethylene oxide, kept for several hours at ordinary temperature.—G. F. M.

Nitrites; Manufacture of aliphatic —. P. R. de Wilde, Geneva, Switzerland. Eng. Pat. 131,304, 29.9.19. (Appl. 23,881/19.) Int. Conv., 25.9.18.

NITRATES of aliphatic alcohols are produced by the reducing action of sulphur dioxide on solutions of the alcohols in pure or diluted nitric acid. *Example*—74 grms. of isobutyl alcohol dissolved in 100 grms. of nitric acid (10° B., sp. gr. 1.384) is treated with gaseous sulphur dioxide until the odour of the gas becomes apparent. A yield of 85 grms. of isobutyl nitrite is obtained. Alternatively, a saturated alcoholic solution of sulphur dioxide may be mixed with the nitric acid, a similar result being obtained.—G. F. M.

3,6-Diaminoacridine; Manufacture of —. W. P. Thompson, Liverpool. From Poulenc Frères and R. Meyer, Paris. Eng. Pat. 137,214, 1.5.19. (Appl. 10,797/19.)

m-PHENYLENEDIAMINE is melted with formic acid or oxalic acid and glycerol or other polyhydric alcohol and a condensing agent, such as zinc or calcium chloride, and diaminoacridine is isolated from the resulting solid mass by treatment with water and ammonia, and may be purified through its sulphate, which is slightly soluble in very dilute sulphuric acid. *Example*—6 kilos of *m*-phenylenediamine, 7 kilos of crude oxalic acid, 10 kilos of fused zinc chloride, and 10 kilos of industrial glycerin (28° B., sp. gr. 1.24) are heated at 130° C., and when evolution of carbon dioxide has ceased the temperature is raised to 150°—170° C. and maintained so for 2 hours to complete the reaction.—G. F. M.

Pyrocatechin [protocatechuic] aldehyde; Preparation of —. L. Schmidt, Munich, Germany. U.S. Pat. 1,326,973, 6.1.20. Appl., 31.3.17.

PIPERONAL is treated with thionyl chloride and chlorine, and the dichloropiperonyl chloride thus formed, on hydrolysis with water, yields protocatechuic aldehyde. (See also Ger. Pat. 278,788; this J., 1915, 249.)—G. F. M.

Chloropierin; Process for producing —. R. J. King, Stamford, Conn. U.S. Pat. 1,327,714, 13.1.20. Appl., 26.11.17.

A SOLUTION of calcium picrate is added to a mixture of bleaching powder and water.—G. F. M.

Tobacco; Process for improving — and removing nicotine. R. von Rothenburg, Darmstadt. Ger. Pat. 314,391, 3.5.16. Addition to Ger. Pat. 301,439.

TOBACCO is treated, during fermentation, with metabolic products of specific tobacco organisms and, at a later stage, with fatty acids and solvents for nicotine. The bacterial cultures may be grown in infusions of leaves of *Prunus odorata* (Dwarf cherry). (Cp. Eng. Pat. 121,598; this J., 1919, 963 A.)—J. H. L.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic rendering of contrast; The fundamental law for the true —. F. F. Renwick. Phil. Mag., 1920, 39, 151—151.

SINCE the characteristic curve of a plate expresses the relationship existing under certain conditions between the light gradations of an object and those of the resulting negative, and a similar relationship between the negative and the print is obtained from the characteristic curve of the printing material, a

combination of these curves will show the relationship between the object and the print. This method was referred to by the author in 1916 (this J., 1916, 1272), and in view of a recent reference by Slade and Porter (Phil. Mag., 1919, 38, 187; this J., 1919, 600A) is now explained in detail. Two instances are given, a neutral-tinted grainless wedge being taken as the object, this giving a very convenient means of impressing a known series of exposures, changing in the same way as do the values of log E along the exposure axis of a characteristic curve. In one case the correspondence between print and object is deduced from known curves for negative and positive material, and in the other the requisite curve of the positive material to obtain a desired print from a known negative material.—B. V. S.

Photographic development; Chemical induction in —. I. Induction and the Watkins factor. S. E. Sheppard and G. Meyer. Communication from The Research Laboratory of the Eastman Kodak Co. Phot. J., 1920, 60, 12—21.

THE accelerating effect of small quantities of potassium iodide on developers, first observed by Lainer in 1891, is only slight except with developers, such as glycin and quinol, which have low reduction potentials, or high induction values. In most cases the effect is merely on the induction period, the Watkins factor being increased. With a quinol-carbonate developer, however, there is also a marked alteration in the degree of development (5), particularly at low temperatures. The accelerating effect starts at very low iodide concentrations, rises to a maximum at which it remains over a certain range, and then rapidly falls to a minus quantity; with quinol, for instance, the maximum effect occurs at concentrations from $N/1000$ to $N/100$, and retardation is obtained at $N/35$ upwards. The possible nature of the iodide action is discussed, especially in connection with the suggestion, previously made, that the first stage in development is formation of a complex of silver halide and reducer. Experiments on the adsorption of safranin by silver bromide, without and with iodide treatment, are adduced in support of this view. Plates bathed in dilute potassium iodide solutions ($N/1000$ to $N/100$), washed and then developed give fog. If such a plate, after washing, is fixed and then developed in an acid developer a black, coarse-grained fog appears, different from the usual fine-grained image obtained by physical development. It is suggested that the fogging effect is due to a nucleus infection of the silver bromide grain.—B. V. S.

PATENTS.

Colour screen plates or films for photography in natural colours; Manufacture of —. M. Wieland, Berlin-Tempelhof, Germany. Eng. Pat. 137,502, 29.8.19. (Appl. 21,263/19.)

A PHENOL-FORMALDEHYDE condensation product is used as the medium in a multi-colour screen. A suitable colouring material is added to the phenol and formaldehyde and the mixture atomised before the condensation is completed. An intimate mixture of different coloured globules so obtained is dusted on to a prepared plate, the excess dusted off, and the plate then heated so that the globules soften and coalesce, and the hardening process completed by heat, and, if necessary, by pressure. A final coat of colourless condensation product is then applied. The resulting screen is unaffected by heat and ordinary solvents.—B. V. S.

Manuscript, typewritten or printed matter, drawn [photographically] —. S. J. Waters, Esher. [photographically] —. S. J. Waters, Esher. U.S. Pat. 1,327,931, 13.1.20. Appl., 9.11.18.

A STENCIL for the reproduction of manuscript etc.

is obtained by printing through the matter, or through a negative of it on to a thin sensitised film, transferring the film to a temporary support for development etc., and then transferring it to a final backing of fine texture.—B. V. S.

Photographic printing paper and process of making the same. T. P. Middleton, Assignor to Kerotype, Ltd., London. U.S. Pat. 1,329,918, 3.2.20. Appl., 21.4.19.

SEE Eng. Pat. 126,149 of 1918; this J., 1919, 441 A.

XXII.—EXPLOSIVES; MATCHES.

Melinite; Estimation of incompletely nitrated phenols in the mother liquors from — by means of bromine. Marquoyrol and P. Carré. Bull. Soc. Chim., 1920, 27, 127—138.

THE mother liquors from the manufacture of melinite contain sodium 2,4-dinitrophenol-*o*-sulphonate and sodium 2,6-dinitrophenol-*p*-sulphonate in varying proportions, together with some mononitrophenolsulphonates and a little picric acid. The action of bromine on either of the dinitrophenolsulphonates in aqueous solution depends upon the temperature and duration of contact with the bromine, and the amount of bromine added in excess. The mononitrophenolsulphonates tend to give dibromoderivatives and the picric acid present is acted on by the bromine. All of these changes tend to vitiate the results obtained by Jolibois' method for the estimation of incompletely nitrated phenol in the mother liquors from phenol. The results by this method are always too high.—W. G.

Melinite; Estimation of incompletely nitrated phenol in the mother liquors from —. Ratio between the composition of these mother liquors and the yield of melinite. Marquoyrol and P. Carré. Bull. Soc. Chim., 1920, 27, 138—140.

ONE HUNDRED c.c. of the mother liquor is concentrated until the boiling-point reaches 125°C ., then 25 c.c. of nitric acid (40°B ., sp. gr. 1.384) is added, the mixture is heated for 15—20 mins. at 115° — 120°C ., and then 10 c.c. more of nitric acid is added and the heating continued until the boiling-point again reaches 125°C .. The liquid is diluted to 100 c.c. with water, the picric acid is collected with the aid of the pump, washed five times with 4 c.c. of water, and titrated with $N/10$ sodium hydroxide, using methyl red as an indicator. It is necessary to add a correction of 0.12—0.16 gm. for the picric acid dissolved during the washing of the precipitate. The results are always a little low. To control the yield from the manufacturing process, the sulphuric acid in the mother liquors must also be determined. In a given case the mother liquors contained 472.7 grms. of sulphuric acid per litre and a quantity of incompletely nitrated phenol equal to 11.9 grms. of picric acid per litre. In the preparation of the phenolsulphonic acids, 100 grms. of phenol required 465 grms. of actual sulphuric acid. Thus in this process there was a quantity of non-nitrated phenol corresponding to $11.9 \times 465 = 472.7$ grms. of picric acid.—W. G.

Picric acid; Transformation of dinitrophenolsulphonic acids into —. Marquoyrol, P. Carré, and P. Lorette. Bull. Soc. Chim., 1920, 27, 110—143.

THE transformation of 2,6-dinitrophenol-*p*-sulphonic acid into picric acid is more rapid than that of 2,4-dinitrophenol-*o*-sulphonic acid. Thus in the manufacture of picric acid it is preferable to use a sulphonated phenol mixture containing the maximum amount of phenol-2,4-disulphonic acid.—W. G.

Picric acid; Preparation of — by the nitric acid process, using nitric acids of different concentrations. Marqueyrot, P. Carre, and P. Lorient. Bull. Soc. Chim., 1920, 27, 143—148.

It is possible to obtain good yields of picric acid in the laboratory by sulphonating 100 grms. of phenol with 350 grms. of 92.5° sulphuric acid on a water bath for three hours and nitrating the mixture with five molecular proportions of nitric acid (31.5° B., sp. gr. 1.28) under such conditions that the nitric acid added is utilised completely. Under laboratory conditions it does not seem possible to use less than these proportions of sulphuric and nitric acids.—W. G.

Nitro-compounds. Florentin and Vandenberghe. See III.

PATENTS.

Hexanitrodiphenylamine; Process of making —. J. Marshall, Swarthmore, Pa., Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,326,947, 6.1.20. Appl., 20.3.19.

2,4-DINITRODIPHENYLAMINE is nitrated with a mixture of nitric and sulphuric acids containing 30% of nitric acid to 2,4,2',4'-tetranitrodiphenylamine, which is then further nitrated to 2,4,6,2',4',6'-hexanitrodiphenylamine by treatment at an elevated temperature with a nitrating mixture containing 20% of nitric acid.—G. F. M.

Explosive. L. O. Bryan and W. R. Swint, Assignors to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,327,859, 33.1.20. Appl., 18.3.19.

THE explosive contains as the main ingredient trinitrotoluol, together with nitroglycerin and a non-explosive inorganic oxygen-carrying salt.—T St.

Nitrostarch explosive and method of manufacturing same. Method of manufacturing nitrostarch explosives. W. O. Snelling and W. R. Laws, Assignors to Trojan Powder Co., Allentown, Pa. U.S. Pats. 1,329,211 and 1,329,212, 27.1.20. Appl., 22.6.18 and 3.9.19.

NITROSTARCH is coated with a heavy mineral oil and then treated with an organic stabilising agent soluble in the oil.—W. J. W.

Nitrocarbohydrates; Chemical process for making —. G. R. Anchors, Landing, N.J. U.S. Pat. 1,329,353, 3.2.20. Appl., 6.8.18.

CARBOHYDRATES are pulfed, then nitrated, and the products are treated with salts of fatty acids.—W. J. W.

Explosive composition. W. G. Hudson, Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,329,525, 3.2.20. Appl., 18.2.18.

AN azide and colloidal nitrocellulose are used as ingredients in explosive compositions.—W. J. W.

Explosives; Method of charging containers with high —. C. A. Woodbury, Middletown township, Pa., Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,329,566, 3.2.20. Appl., 23.5.18.

CONTAINERS are filled with a mixture prepared by dissolving picric acid in melted trinitrotoluene and then dissolving trinitroxylenes in the solution, the mixture being kept at a temperature above the melting point of trinitrotoluene during the operation.—W. J. W.

[Nitrocellulose;] Process of gelatinising [liquids containing —], and product thereof. J. E. Crane, Newark, N.J., Assignor to The Arlington Company, Arlington, N.J. U.S. Pat. 1,329,583, 3.2.20. Appl., 2.11.16.

BASIC lead acetate is added to liquids containing nitrocellulose as a gelatinising agent.—W. J. W.

Explosive; Process for producing a propellant — relatively insensitive to shock. Zentralstelle für wissenschaftliche-technische Untersuchungen, G.m.b.H., Neubabelsberg. Ger. Pat. 298,539, 15.6.16.

THE nitro-compound, $C_6H_5N_2O_6$, obtained by nitration of hexamethylenetetramine, is incorporated with nitrocellulose, if necessary with the aid of volatile solvents such as ether-alcohol mixtures or acetone or of non-volatile or slightly volatile nitro-compounds which gelatinise nitrocellulose, e.g., di- or trinitro-benzene, -toluene, or -anisole.—J. H. L.

Match-head composition. J. R. Mardick, New York. U.S. Pat. 1,329,537, 3.2.20. Appl., 20.5.19.

A PERCHLORATE is employed as the oxidising agent in match compositions.—W. J. W.

Volatile solvents. Ger. Pat. 303,396. See I.

XXIII.—ANALYSIS.

Hydrogen ion concentration; Determination of —. J. W. M. Bunker. J. Biol. Chem., 1920, 44, 11—11.

A MODIFIED form of bubbling electrode used in a closed vessel is described.—J. C. D.

Plant juices; Accurate determination of the hydrogen-ion concentration of — by means of the hydrogen electrode. C. B. Clevenger. Soil Sci., 1919, 8, 217—226.

AN apparatus is described, the essential details of which are a modified Clark electrode vessel, adapted for work with plant juices, and calomel electrodes immersed in a constant temperature water bath. The apparatus is so arranged that the plant juice is saturated with hydrogen outside the electrode vessel and only comes into contact with the electrodes just prior to the readings being taken. Contact between the plant juice and the saturated solution of potassium chloride is made by means of a scratch round the cock connecting the two, as the contact potential develops quite rapidly if the connection is made by opening the cock wide. Duplicate measurements usually agree within 0.1 millivolt and constant potentials are maintained for several minutes. The plant juice is prepared by macerating the tissue, wrapping it in a muslin cloth, and expressing the juice with a press. By this means a juice free from coarse colloidal and other material is obtained.—W. G.

Arsenious anhydride; Use of — in volumetric analysis. F. de Bache. Annali Chim. Appl., 1912, 12, 136—142.

THE volumetric method of Namias (Gazz. Chim. Ital., 1892, 22, 508) consisting in adding an excess of arsenious anhydride to any oxidising agent, in the presence of ammonium acetate, and titrating the excess in the hot liquid by means of iodine in the presence of acetic acid, using starch paste as indicator, is found to give inaccurate results.

—C. A. M.

Arsenious anhydride; New volumetric reduction methods with —. F. de Bache. Annali Chim. Appl., 1919, 12, 153—171.

THE method depends upon treating the oxidising agent with an excess of arsenious acid solution in the presence of hydrochloric acid and titrating the excess with potassium bromate solution. In some cases the solution requires boiling to effect complete oxidation of the arsenious acid, and in order to avoid loss of arsenic chloride by volatilisation the proportion of hydrochloric acid must not exceed 12.8%. In the case of potassium permanganate

solution the oxidation is complete in a short time at the ordinary temperature. For the reduction of potassium chlorate in boiling solution a large excess of the arsenious acid solution is required. For the analysis of bleaching powder and hypochlorites the proportion of hydrochloric acid should be reduced to 5%. By increasing the acid concentration to 12% and effecting the reduction at the boiling point both chlorates and hypochlorites will react. Perchlorates do not interfere with the determination. Chromates are completely reduced in about an hour at the ordinary temperature or preferably at boiling point. The method may be applied to insoluble chromates, such as lead chromate.—C. A. M.

Cobalt; A sensitive reagent for —. I. Bellucci. Gazz. Chim. Ital., 1919, 49, ii., 294–298.

By means of α -nitroso- β -naphthol, 1 mgrm. of dissolved cobalt in 1–2 litres of water may be detected colorimetrically, and by means of β -nitroso- α -naphthol 1 mgrm. in about 17 litres of water. Dimethylglyoxime permits of the detection of 1 mgrm. of nickel in 4–5 litres of water. (See also Atack, this J., 1915, 641; Jones, this J., 1918, 630A; Bellucci and Chincini, this J., 1920, 46A.)—T. H. P.

Phosphoric acid; Determination of — as ammonium phosphomolybdate. A. Stutzer. Landw. Versuchs-Stat., 1919, 91, 251–264.

THE following procedure is recommended:—From 15 to 25 c.c. of the phosphate solution, containing not more than 0.25 grm. P_2O_5 , is mixed with 25 c.c. of nitric acid (sp. gr. 1.20) containing 3% by vol. of sulphuric acid, the mixture is heated to about 80° C., and 100 c.c. of molybdic acid solution (molybdic acid, 5, ammonium sulphate, 25 grms., ammonia, sp. gr. 0.96, 20 c.c., nitric acid, sp. gr. 1.2, 65% c.c., water to 100 c.c.) is added, the whole is cooled, the precipitate collected on a weighed asbestos filter, washed with cold 2% ammonium nitrate solution, then with alcohol or acetone, dried for 1 hr. at 100° C., and weighed. The factor for calculating the weight of the precipitate into P_2O_5 is 0.03513.—W. P. S.

Oxygen; Determination of — with cuprammonium solution. W. Hachnel and M. Mugdan. Z. angew. Chem., 1920, 33, 35.

SATURATED ammonium chloride solution may be used in the preparation of the cuprammonium solution used for the absorption of oxygen, and possesses the advantage over ammonium carbonate that the residual gas, after removal of ammonia by sulphuric acid, does not contain any carbon dioxide derived from the cuprammonium solution.

—W. P. S.

Sulphur; Apparatus for the determination of —. C. Hofrichter. Chem.-Zeit., 1920, 44, 110.

AN apparatus for the determination of sulphur by the evolution method consists of a reaction flask provided with a short vertical condenser; the stem of a funnel extends through the condenser to the bottom of the flask, and a side tube leads from the top of the condenser to a vessel containing the absorption solution. The material is placed in the flask, hydrochloric acid is added through the funnel, and the top of the funnel is then closed by a bent bulb tube containing a few drops of water; this valve prevents the absorption solution from being drawn back into the flask when the pressure in the latter decreases from any cause. All parts of the apparatus are of glass, and are connected by ground-in joints.—W. P. S.

Mercury; Determination of —. H. B. Gordon. Analyst, 1920, 45, 41–46.

MERCURY in very dilute acid solution may be deter-

mined by depositing it on copper gauze, then heating the copper in hydrogen and noting the loss in weight due to the volatilisation of the mercury. The volatilised mercury may be converted into mercuric iodide by the action of iodine vapour. As little as 0.1 mgrm. of mercury in 2 litres of solution may be detected and determined. The presence of nitrates does not interfere; arsenic, bismuth, antimony, and silver interfere to some extent, but it is probable that by heating the copper gauze carefully to avoid volatilising these elements with the mercury the method might be used in their presence.—W. P. S.

Colour lakes; Theory of —. [Detection and determination of cobalt, copper, and other metals.]

C. Brenner. Helv. Chim. Acta, 1920, 3, 90–103. ATTEMPTS are described to base methods for the detection and estimation of small amounts of cobalt and copper on the colorations which the metallic ions give with nitrosonaphthols. α -Nitroso- β -naphthol is unsuitable for this purpose in aqueous solution since the lake is too easily precipitated, whilst chloroform or carbon bisulphide solutions (in which cobalt nitrosite is freely soluble) are only adapted to the detection and not to the estimation of cobalt. On the other hand, the solubility of the lake in water can be sufficiently increased by introducing one or more sulphonic groups into the naphthol molecule. The colour of the lake depends on the number and position of the hydroxy- and sulphonic-groups; the yellowest shade is given by the nitroso-derivative of R acid, the deepest red with nitroso-1-naphthol-5-sulphonic acid, and the darkest shade with nitroso-1,8-dihydroxynaphthalene-3,6-disulphonic acid (chromotrope acid). Chromotrope acid can be used for the micro-titration of cobalt since the yellow ammoniacal solution of nitrosochromotrope acid yields an immediate intense-blue coloration with the cobalt ion, in the formation of which 2 mols. of the acid react with an atom of cobalt; when the cobalt ions have been completely converted into this compound, further addition of the acid causes a change in shade from blue to red. The method is fairly accurate, but it cannot be used for cobalt in the presence of nickel, although the latter alone may also be estimated by this reagent. The micro-titration of copper can be effected similarly, but a larger excess of the reagent is required to give a definite end-point. Other substances with properties similar to those of nitrosochromotrope acid are found among azo-dyes which are used with metallic mordants, and among those which, in dyeing, are subjected to after-chroming. Thus, Diamond Black F gives a deep-blue solution in aqueous alkali, which yields differently coloured lakes with ammoniacal solutions of the most diverse metals; when the metallic ion is completely united with the dye, addition of a further quantity of the latter causes a change in shade towards blue. The possible applicability of the method is illustrated by the instance of copper. The possibilities of the formation of differently coloured complex compounds have been investigated for twenty different metals and sixteen dyes; such compounds appear to be formed most frequently with magnesium, the alkaline-earth metals, and those of the iron group. Chromium is allied in this respect with the least reactive metals of the nitrogen family. The capability of the dye to form differently coloured complex compounds which are soluble in ammonia appears to depend on the presence of a hydroxy-group in the *ortho*- or *para*-position to the azo-group, and, as a result of extensive experiments with a number of dyes, it is possible to give methods for the micro-chemical estimation of copper, silver, magnesium, zinc, cadmium, calcium, strontium, barium, iron, nickel, and cobalt. (See further J. Chem. Soc., 1920, ii., 194.)—H. W.

Chlorine or bromine; Estimation of organic — by the chromic acid method. P. W. Robertson. Chem. News, 1920, 120, 51.

CERTAIN modifications are suggested to overcome minor difficulties encountered in the chromic acid method of estimating organic chlorine or bromine (this J., 1915, 819). The chromic acid may be replaced by halogen-free potassium bichromate, and a freshly prepared, cold solution of sodium peroxide is preferable as an absorbing medium. Instead of $N/10$ solutions, $N/20$ solutions of silver nitrate and ammonium thiocyanate are recommended. In the case of compounds, particularly liquids, which react explosively with the oxidising mixture the best procedure is to cover the substance with a large amount of powdered bichromate and run the previously cooled sulphuric acid very rapidly into the reaction vessel through a wide funnel by means of a suction pump connected with the absorption tube. The reaction vessel is cooled in ice until the initial violence of the oxidation has moderated.—G. F. M.

Fehling's solution; Behaviour of — in light. I. Bolin and G. Linder. Z. physik. Chem., 1919, 93, 721—736.

WHEN Fehling's solution in glass vessels is illuminated with the light from a carbon arc, cuprous oxide is produced. The reaction has no temperature coefficient and there is no evolution of gas. When the light is shut off the reaction ceases. In quartz vessels the same reaction occurs, but it has a temperature coefficient of 1.2, and there is an evolution of gas after illumination for several hours. On shutting off the light the reaction continues for some time. (See also J. Chem. Soc., 1920, ii., 144.)—J. F. S.

Indole; Quantitative estimation of — in biological media. H. F. Zoller. J. Biol. Chem., 1920, 41, 25—36.

By utilising a modification of the nitroso-reaction for indole a colorimetric method for the quantitative estimation of that substance has been elaborated. The colour produced by applying the modified nitroso-test to the distillate from the solution containing indole is compared with that given by solutions containing known quantities. (See further J. Chem. Soc., 1920, ii., 203.)—J. C. D.

I.—GENERAL; PLANT; MACHINERY.**PATENTS.**

Grinding, crushing, or pulverising machine. O. Wauthier, Brussels. Eng. Pat. 13,878, 8.6.14.

A CYLINDRICAL casing with horizontal axis is split longitudinally for access to the interior. Concentric with the casing is a shaft carrying, say, four discs in which are cut radial slots to form the bearings for the axles of rolls, which are thus supported in the spaces between the discs. Grinding takes place between the cylindrical surfaces of the rolls and outer casing, the rolls being rotated by the friction and pressed outwards by centrifugal force.

—B. M. V.

Grinding and pulverising materials. W. C. Kirby, Harbury Station, and E. L. Lakin, Leamington Spa. Eng. Pat. 138,411, 21.1.19. (Appl. 2213/19.)

GRINDING bodies for use in tube and similar mills are made of hard material, such as cast steel, in the form of discs with their thickness less than their diameter. They are perforated with one or more holes in the axial direction and may be cylindrical or with the angles between the ends and the periphery rounded off; their end faces may also be flat or corrugated.—B. M. V.

Liquefying gases or gaseous mixtures; Process and apparatus for cooling or —. M. Zack, Zürich, Switzerland. Eng. Pat. 129,292, 4.7.19. (Appl. 16,774/19.) Int. Conv., 30.5.18.

THE apparatus consists of a two-cylinder compressor with the cranks at 180° and the cylinders connected by two sets of pipe-coils controlled by valves, the second set of intercommunication pipes being concentric with and outside the first set; the cylinders are also surrounded by a common jacket or casing. The cycle of operation is as follows:—Gas that has been purified, pre-compressed, and pre-cooled, is admitted to a heat interchanger, where it gives up more heat to the final remainder of non-liquefied gas issuing from the apparatus. From the heat interchanger the gas is admitted to one end of one cylinder (say the top of the left-hand one) and on the down-stroke of the piston expands while doing external work; on reaching the dead centre the gas is allowed to pass through the inner set of pipe coils to the underside of the right-hand piston (which has on its up-stroke been producing a vacuum), again expanding but without doing external work. Upon the commencement of the next stroke the intercommunication is shut off and the gas in both cylinders compressed while the cylinders are kept cool by means of their jackets, which are preferably filled with the non-liquefied remainder of the gas; at a certain point in the stroke, determined by the setting of the valves, the outer communicating pipe-coils are opened and the compressed gas passes from the bottom of the right-hand cylinder to the top of the left-hand cylinder and *vice versa*, again without doing external work, this movement continuing until the other dead centre is reached. Liquefied gas is removed by suitable means from both sets of cross connecting pipes and the non-liquefied gas finally allowed to exhaust into the jacket surrounding the cylinders and thence to the first-mentioned heat interchanger. The gas is expanded with external work at a comparatively high, and without external work at a comparatively low temperature.

—B. M. V.

Mixing apparatus. R. B. Grey, London. Eng. Pat. 138,286, 5.9.19. (Appl. 21,830/19.)

A CIRCULAR tank is provided at the bottom with a stirrer which produces a vortex, and, at various

distances above the stirrer with baffles which can be adjusted individually as to height by means of rods brought through the cover of the tank.

—B. M. V.

Filter apparatus. A. R. Peck, Los Angeles, Cal., U.S.A. Eng. Pat. 138,657, 22.10.19. (Appl. 17,256/18.)

FILTER-LEAVES project from fixed cover-plates which carry valves and pipes for mud to be filtered, wash water, and, if desired, compressed air. Removable chambers, mounted on wheels rolling on the channel iron framework of the apparatus, can be bolted to the fixed cover-plates. During the filtering and washing period the chambers are bolted to the cover-plates and the mud or wash water admitted through valves in the cover-plates to the interior of the chambers, whence the liquor passes through the filter-leaves and out through other valves in the cover-plates. When the cakes are built up and washed, the enclosing chambers are moved out of the way without disturbing the cakes and the cakes finally caused to drop off by means of compressed air.—B. M. V.

Filter-press plate. Filter-press device. G. F. Miller, New York. U.S. Pats. (A) 1,330,331 and (B) 1,330,332, 10.2.20. Appl., 22.1 and 14.1.19.

(A) A SUPPORTING frame contains field plates, and a longitudinal recess is made in the upper portion of each field plate to form a conduit in conjunction with the frame. (B) In order to be able to vary the thickness of the filter-cake, alternate field plates are divided, the two halves being made to move outwards from each other within the frames by means of cams or other devices operated by rods rotatable from the outside of the press.—B. M. V.

Filter. O. Baumgartner, Vienna, Ger. Pat. 315,317, 14.3.16. Int. Conv., 6.11.15.

A VESSEL is fitted with a sieve, against the underside of which cork dust or similar light, floatable, granular material is pressed and kept in position by the passage of the liquid through the filter from below. The filtering material may be cleaned by stirring it by hand or mechanically while passing a current of water under pressure through the sieve, or the liquid in the apparatus may simply be withdrawn until the level is below the sieve when the filter mass breaks up, thus allowing the impurities to sink to the bottom.—A. R. P.

Vacua; Methods of and apparatus for producing —. Western Electric Co., Ltd., London. From Western Electric Co., Inc., New York. Eng. Pat. 138,745, 20.3.19. (Appl. 6951/19.)

IN apparatus using the vapour of boiling mercury (or other liquid) to withdraw the last traces of air (or other gas) from a vessel, the walls of the conduit conveying the stream of mercury vapour are cooled at a point in front of the place where the air being exhausted is admitted to the stream, with the object of removing, by condensation, those molecules of mercury vapour which are not moving substantially in the direction of the stream, and which if not removed would heat back molecules of issuing air and prevent proper exhaustion.—B. M. V.

Raising and forcing water and other liquids; Means for —. R. A. Swainson, Newcastle-upon-Tyne. Eng. Pat. 138,758, 22.5.19. (Appl. 8328/19.)

THE liquid is raised and expelled from a pair of pumping chambers by means of the alternate exhaustion and compression of air above the liquid, float valves being provided so that no liquid can be drawn into the air pipes and no unnecessary work is done in producing too much vacuum or too much compression on varying suction and delivery heads.

—B. M. V.

Furnaces for steam boilers, kilns, and the like. J. Nash, Westcliff-on-Sea. Eng. Pat. 138,762, 9.4.19. (Appl. 9017/19.)

THE fire-box of the furnace is provided with two internal arches extending from the back towards, but not as far as, the front, the upper arch being shorter than the lower. A fire is built on the front of the lower arch as well as on the usual fire-bars or bottom hearth; the fires may be stoked alternately so that there is always incandescent fuel exposed, which promotes consumption of smoke.—B. M. V.

Tunnel-kiln. G. H. Benjamin, New York. U.S. Pat. 1,329,745, 3.2.20. Appl., 23.5.19.

A TUNNEL oven comprises a main chamber, a number of independent heating chambers arranged longitudinally in line on each side of the main chamber, and air flues situated behind and in front of each chamber. A screen is arranged in front of each chamber, with means for moving the screens to and from the chamber in front of which they are individually placed.—B. N.

Tunnel kiln combustion chamber. Tunnel kiln. P. d'H. Dressler, Zanesville, Ohio, Assignor to American Dressler Tunnel Kilns, Inc., New York. U.S. Pats. (A) 1,330,432 and (B) 1,330,433, 10.2.20. Appl., 28.5.19.

(A) A COMBUSTION chamber has a hollow wall to provide an air-circulating passage open at the ends; a window opens from the passage to the outer wall surface. (B) A tunnel kiln is provided with a preliminary heating zone between the entrance and the high-temperature zone. A combustion chamber in the high temperature zone is separated from the heating chamber by conducting walls, and is provided with an "extension space" extending through the preliminary heating chamber. A cooling fluid is supplied to the "extension space." —W. F. F.

Ring-furnace. B. E. Broadwell, Badin, N.C., Assignor to Aluminium Co. of America, Pittsburgh, Pa. U.S. Pat. 1,330,164, 10.2.20. Appl., 22.1.18. Renewed 5.9.19.

THE bottom, side walls, and end walls of the heating chamber are hollow. Air or gas enters a hollow end wall at the bottom and passes out at the top to a transverse conduit, and thence to the upper part of the hollow side wall of the furnace. The air or gas is then delivered into the upper part of the furnace chamber, which is provided with longitudinal partitions forming baffles, and the gas passes out at the bottom into the hollow bottom of the chamber. The gas passes from the flues in the hollow bottom to the second end wall and upwards through the hollow wall to the outlet at the top. —W. F. F.

Ring furnace. V. C. Doerschuk, Massena, N.Y., Assignor to Aluminium Co. of America, Pittsburgh, Pa. U.S. Pat. 1,330,175, 10.2.20. Appl., 1.5.19.

THE heating chamber is divided into compartments by longitudinal vertical partitions provided with internal flues. The end walls of the chamber are also hollow and are provided with vertical flues and with burner ports above the flues. The burner ports open directly into the flues in the vertical partitions and also into similar flues in the side walls, and means are provided for delivering fuel gas to any desired series of burner ports. The ports open into their respective flues in the direction of the flow of air.—W. F. F.

Rotary furnaces; Sectional lining for —. W. S. Rockwell, Assignor to W. S. Rockwell Co., New York. U.S. Pat. 1,330,219, 10.2.20. Appl., 8.9.19.

A ROTARY furnace having a refractory lining is pro-

vided with a cylindrical inner metallic lining in sections, each section being provided with a portion of one or more helical ribs so that when the sections are all in place the ribs are continuous and form a spiral channel with entirely metallic walls.

—B. M. V.

Furnace. S. S. Amdursky, Rochester, N.Y. U.S. Pat. 1,330,227, 10.2.20. Appl., 14.5.18.

A TWIN furnace contains two upright crucible chambers heated by separate burners. A connecting conduit tangential to both chambers allows the heated products to pass from either chamber to the other.—T. St.

Retort; Rotary —. C. Francke, Berlin. Ger. Pat. 314,546, 28.3.18.

A CYLINDRICAL retort rests horizontally on two rollers at one end. To the other end is fixed a grooved collar which can turn inside a ring with an internal rib which engages with the groove of the collar. The ring is supported on rollers by which it is caused to revolve.—H. J. H.

Shaft furnace for burning lime, dolomite, etc., with built-in gas producer. E. Skuballa, Berlin. Ger. Pat. 314,586, 12.7.17.

THE gas producer is annular in shape and surrounds the shaft of the kiln, being separated from the latter only by the gas and air passages. The top of the producer is at the level of and forms the charging floor of the kiln. The bottom of the producer is a ring-shaped mechanically driven revolving grate, which delivers ash into hoppers placed below. Regularity in the heating of the charge is claimed.—H. J. H.

Rabbles or other agitators or stirrers. W. H. Sayre, Glen Ridge, N.J., U.S.A. Eng. Pat. 138,802, 11.6.19. (Appl. 14,787/19.)

IRREGULAR lumps of hard material, such as alundum, are embedded in the arms of rabbles or blades of pug-mills etc. in such a manner that the projecting lumps take most of the wear.—B. M. V.

Drying material; Method of and apparatus for —. O. D. Rice, Winthrop, Mass. U.S. Pat. 1,328,897, 27.1.20. Appl., 15.1.19.

A VACUUM drying chamber is provided inside with a fan which maintains a heating and drying medium in continuous circulation over the material to be dried within the chamber. Means are provided for heating the drying medium and for withdrawing moist vapours from the chamber by suction.—J. H. L.

Drying solids; Process of —. R. W. G. Stutzke, Assignor to The G. A. Buhl Co., Chicago, Ill. U.S. Pat. 1,329,813, 3.2.20. Appl., 28.3.17.

SOLIDS are continuously introduced into a closed system through which there is set up a circulation of vapours which are superheated during their circulation, and the system is provided with a vent to limit the rise of pressure.—B. N.

Dryer. B. M. Kuhn, Bloomington, Ill. U.S. Pat. 1,330,195, 10.2.20. Appl., 25.2.18.

MATERIAL to be dried is supported on a horizontal reticulated partition dividing a drying chamber into two parts. Hot air is supplied to the lower compartment and passes upwards through a reticulated flue which rests on and is movable over the surface of the reticulated partition.—W. F. F.

Desiccating apparatus. A. D. Robinson, Logan, W. Va. U.S. Pats. (A) 1,330,746 and (B) 1,330,747, 10.2.20. Appl., 17.10 and 11.11.18.

(A) The material to be dried, e.g., eggs or the like, is supplied to a belt passing over a drum, by means

of a number of discharge heads arranged transversely to the belt. A pivoted rocker arm projects inwards from the periphery over the end face of the drum, and a pin carried by the drum comes into contact with the arm at every revolution. The arm is adapted to open the discharge openings of all the supply heads simultaneously, and the material is spread on the belt by a revolving brush. (n) The drying belt passes horizontally through a hot air chamber just below a horizontal partition. This partition is perforated with elongated openings arranged transversely, their length being equal to the distance between them. The transverse rows are arranged so that the perforations in adjacent rows are out of line. Air is admitted into the chamber and deflecting strips are provided to equalise the flow of air through the perforations.

—W. F. F.

Dryer; Cylindrical —. W. Greding, Cronberg. Ger. Pat. 313,148, 23.6.16.

A NUMBER of grooves in planes normal to the axis are provided on the periphery of a cylindrical dryer, *a*, constructed of sheet-metal. The moist material is conveyed to the grooves, and the cylinder is sur-

rounded by an endless perforated band, *h*, which rests against the projections between the grooves and moves with the same velocity as the drum. The dried material is removed by a scraper, *m*, and is carried by the band, *h*, to the discharge trough, *k*.

—L. A. C.

Drying apparatus; Tubular —. K. Wagner, Dresden. Ger. Pat. 315,862, 13.3.18.

THE apparatus comprises a network of tubes through which air circulates, and a series of heaters placed in the meshes of the network. The air current flows in an opposite direction to the material and serves to cool the latter when dry.

—W. J. W.

[Electrically] precipitating suspended material from furnace-gases; Method of —. Precipitating suspended material from gases. Method of collecting suspended material from furnace-gases. E. R. Wolcott, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pats. (a) 1,329,737, (n) 1,329,817, and (c) 1,329,818, 3.2.20. Appl., (a) 19.3.19, (n) 5.7.17, and (c) 29.4.18.

(a) Water is supplied to the gases to humidify them to a condition of partial saturation, and partially to cool them; the gases are then further cooled and the suspended particles precipitated by electrical action. The temperature of the precipitated material and the relative humidity of the gases are

controlled in such a manner as to provide sufficient moisture in the precipitated material to prevent accumulation of electric charge thereon, but not sufficient to make the deposit corrosive or adherent to the surfaces on which it is precipitated. (n) The dielectric strength of the precipitating electrical field is maintained, in cases where the precipitated material is non-conducting and tends to accumulate a charge by the action of the electrical field, by applying to the deposit an agent capable of increasing the conductivity thereof sufficiently to discharge the same without rendering the deposit fluid. (c) Suspended material is separated from hot furnace gases by injecting water into the gases to humidify and cool them, the gases being then passed through an electrical field. The surfaces of the collecting electrodes are maintained sufficiently cool to condense water on the precipitated material, the temperature of the gases and the collecting electrodes being so controlled as to cause sufficient condensation of water to form a fluid deposit with the material on the collecting electrodes.—B. N.

Electrical treatment of gases; Apparatus for —. W. A. Schmidt, Los Angeles, Cal., and L. Bradley, East Orange, N.Y., Assignors to Research Corporation, New York. U.S. Pat. 1,329,859, 3.2.20. Appl., 24.6.16.

THE apparatus is provided with inlet and outlet manifold chambers, with a number of pipes extending between them, through which the gases are passed. Discharge electrodes consisting of wires are suspended in the pipes and kept taut by weights, and are insulated from each other. Water is sprayed into the hot gases to cool them before subjecting them to the action of the electrical field.

—B. N.

Electrical purification of gases; Process and apparatus for —. H. Püning, Münster. Ger. Pat. 315,262, 22.1.18.

THE insulators are enclosed in downwardly-directed containers filled with heavy gases or with cooled gases; alternatively, upwardly-directed containers are used for light gases or the gases are heated during the operation. The filling of the containers with gases may be brought about by the introduction of small quantities of liquids which are converted into vapour. In this way the insulators are protected from dust and impurities. The loss by diffusion of the gas from the containers during purification is made up by the addition of more gas from time to time.—A. R. P.

Hot gases; Process for removing dust from —. R. Vetterlein, Schöningen. Ger. Pat. 303,831, 14.3.16.

THE hot gases are led through a spray of a salt solution which is thus evaporated, the dry salt falling to the bottom of the vessel together with any dust present in the gas, whilst the steam, together with any gaseous compound formed by interaction of the gases and the salt, passes into the original gas mixture. For example, the hot gases obtained by roasting pyrites are treated with a solution of a nitrate or nitrite whereby the latter is converted into a sulphate which falls to the floor together with any dust, and the gases are charged with steam and oxides of nitrogen.—A. R. P.

Leaching tank. W. E. Giesecke, Assignor to Ray Bros. Corp., New York. U.S. Pat. 1,330,463, 10.2.20. Appl., 31.3.17.

THE lower part of the wall of a tank, which may be shaped as a frustum of a cone, is perforated and covered with filtering material. An outer wall or a series of spaced shells are placed over the filtering area and are provided with a pipe and valve. There may also be another outlet in the bottom of the tank.—B. M. V.

Dissolved or suspended particles; Process for separating — from liquids. I. Ebers, Ahrensburg. Ger. Pat. 306,481, 22.6.15.

THE liquid is vaporised by heating to a temperature above its boiling point, and the vapours are carried forward with solids in suspension by a current of warm air and caused to pass through a filter medium which retains solid particles. The process is adapted to the evaporation of sea water, soap solutions for the production of soap powder, and to the preparation of dried milk.—H. J. H.

Volatile substances; Process for removing — from aqueous solutions. H. Wehner, Frankfurt. Ger. Pat. 314,518, 3.3.18. Int. Conv., 13.2.15.

By means of suction applied at the top, finely divided air is drawn through the liquid in vertical tubes formed with a series of alternate constricted and enlarged portions. The froth rises to the top of the tubes, and overflows to a horizontal main in which the air and vapour separate from the liquid, which flows away. If it is desired to effect a chemical reaction at the same time, means are provided for drawing an appropriate reagent into the bottom of the tubes.—H. J. H.

Chimney gases; Apparatus for cooling —. E. Eckmann, Harleshausen. Ger. Pat. 314,739, 25.5.17.

THE cooler consists of a transverse arrangement of air channels and a central air shaft, with water distributors between successive channels, the water being kept cool by introduction of fresh air and evaporation thereby reduced to a minimum.—W. J. W.

Fine-grained material; Process and apparatus for charging — into chambers with exclusion of air. K. Eltze, Mannheim-Käfertal, and R. Blume, Sürth. Ger. Pat. 315,091, 16.8.18.

THE process applies to the charging of silicon into caustic soda for the preparation of hydrogen. Water is forced through the mass of fine-grained silicon, thus driving it through a tube or channel into the gas-generator containing hot caustic soda solution and from which air is excluded. The pressure used in the operation is equal to the highest pressure in the generating vessel, so that regulation of the gas supply is possible.—A. R. P.

Decolorising material or filter-charcoal. Westfälische Mineralölwerke W. H. Schnitz und G. von der Heyde, Dortmund. Ger. Pat. 315,647, 23.3.16.

DECOLORISING materials of the nature of fullers' earth and filter-charcoal, are rendered more porous by addition of granulated slag produced in the blowing of basic pig-iron or other metallurgical product, which in itself possesses bleaching properties.—A. R. P.

Crushing stone, ore, and the like materials; Machines for breaking or —. E. Helme, Leeds. Eng. Pat. 138,387, 12.11.18. (Appl. 18,475/18.)

Grinding or pulverising ores, clinker, or the like; Process and apparatus for —. R. Forsyth, Hancock, Mich., U.S.A. Eng. Pat. 138,466, 13.5.19. (Appl. 6329/19.)

II A.—FUEL; GAS; MINERAL OILS AND WAXES.

Low temperature carbonisation; Investigation of the suitability of German coals for —. I. Coals from the German Upper Silesian coalfield. F. Fischer and W. Glud. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 1—38. Chem. Zentr., 1919, 90, IV., 1064—1066.

PROXIMATE analyses of 25 coals from the area Czernitz-Birkental and Zabrze-Laurahütte are given, and the specific gravities at 25° and 50° C. of the low-temperature tars, together with their phenol content. The resulting semi-cokes are described and the yields of gas given. The revolving cylindrical retort previously described (this J., 1919, 563 A) was used, modified by the addition of a centrifugal tar extractor analogous to the Theisen washer. The caking coals gave a semi-coke in the form of balls which resisted crushing in the hand, but broke up when dropped on a stone floor. Non-caking coals gave a coke retaining the structure of the original coal, even when carbonised throughout, but varying much in hardness. Carbonisation in presence of steam frequently led to increased yield of tar. The yield and quality of the tars showed the Upper Silesian coals to be very well adapted to low-temperature carbonisation. The geologically youngest seam gave the highest yield of tar. Most of the Upper Silesian coals are gas coals resembling the younger formations of the Ruhr coal field, although some of the older formations are of the same geological epoch as the Ruhr lean coals. The great difference in tar yield, i.e., in the bitumen content of the two coals is to be explained by modification occurring since the strata were deposited. This may be a sort of condensation of the bitumen similar to that observed with low-temperature tar in an autoclave (cf. this J., 1920, 223 A). The variation in caking power may be connected with such a transformation. In order to get good compact coke from gas coal it is desirable to imitate, if possible, the natural transformation process or by working at a suitable temperature to transform the bitumen artificially. Possibly the behaviour on low-temperature coking may afford a new method of classifying coals.—H. J. H.

Low-temperature carbonisation; Investigation of suitability of German coals for — II. Coals from the Lower Rhineland and Westphalian district and Ibbenbüren. F. Fischer and W. Glud. Ges. Abhandl. Kenntn. Kohle, 1919, 3, 248—269. Chem. Zentr., 1919, 90, IV., 1066—1067. (See also preceding abstract.)

TWENTY-SIX samples of coal were examined covering all grades and including two cannels. The cannel gave the greatest yield of tar (37% on the ash and moisture-free coal). As the age of the coal increases the yield decreases, becoming zero with the less bituminous varieties. The tar from cannel was exceptionally low in phenol content. It consisted almost exclusively of hydrocarbons with an exceptional proportion of solid paraffins, being thus specially suited for lamp oil, lubricating oil, and paraffin production. The residual semi-coke was too friable to be used. The yield of tar from the long-flaming gas coals ranged from 6% to 16%, with a mean of 12% on the ash and moisture-free coal. The yield of phenol from these tars is the highest of all, reaching 40—45%. Contrary to the behaviour of the Upper Silesian coals which are otherwise very similar, they yield in most cases a poorly caking semi-coke. The coal from the upper seams, however, gave a fairly hard coke which might serve as a fuel without further treatment. These coals seem adapted for the production of low-temperature tar in gas producers and possibly even of a semi-coke. The more typical gas coals are characterised by the appearance of greater abnor-

malinity in the behaviour of individual coals not in accord with the geological stratification. The yield of tar from the gas coals varied in most cases from 5% to 10.7%, with an average of 8.2% on the ash and moisture-free coal. The phenol content was about 35%. The semi-coke obtained showed the beginning of marked caking power. The tar from the bituminous coals with lower volatile matter was 1.4%–5.3% with a mean of 3.8% on the ash and moisture-free coal. The phenol content of the tar was only 25%. The specific gravity of the tar was abnormal (1.09). The semi-coke was thoroughly caked. The non-bituminous coals give a considerable yield of volatile products and a semi-coke which resembled in external appearance the original coal. The Hbbenbürer coals resembled the older bituminous coals, and indeed were a transition between them and the non-bituminous kinds. They gave an average yield of 2–2.5% of tar and were unsuitable for low-temperature coking. The specific gravity and phenol content of the tar were unusually high.

—H. J. H.

Low-temperature carbonisation; Investigation of the suitability of German coals for —. III. Coals from the Saar district. F. Fischer and W. Glund. Ges. Abhandl. Kemtn. Kohle, 1919, 3, 270–286. Chem. Zentr., 1919, 90, IV., 1067–1068 (cf. preceding abstracts).

The Saar coals differ from those of the Ruhr and Upper Silesian coalfields in that oceanic influences have been absent during deposition and that the non-bituminous varieties do not occur in this region. They yielded from 6% to 15.6% of low-temperature tar. In specific gravity and phenol content the tars were as normally found with such rich coals. The semi-coke produced was very fragile and mostly fell to powder. That from the Wahlschieder seam was remarkable for its resemblance to wood charcoal.—H. J. H.

Low-temperature carbonisation. F. Fischer and W. Glund. Ber., 1920, 53, 250–251.

The authors maintain their scientific and technical priority against Tern (this J., 1920, 54A).—H. W.

Nitrogen of coal; Distribution of the — on low-temperature carbonisation. W. Glund and P. K. Breuer. Ges. Abhandl. Kemtn. Kohle, 1919, 3, 227–237. Chem. Zentr., 1919, 90, IV., 1066.

The distribution of nitrogen in Lohberg gas coal containing 1.86% N (maximum figure by Kjeldahl method) after distilling 10 kilos. in the revolving cylindrical retort as previously used (this J., 1919, 563A) was as follows: In the semi-coke 66.1%, as ammonia 1.8%, as pyridine 0.4%, in the tar 4.4%, as free nitrogen 10.8%. The sum of these is 83.5%, leaving 16.5% unaccounted for, which must be ascribed to the inexactitude of the Kjeldahl method (cf. Terres, this J., 1919, 399A). With coke the error may reach 0.5%, which suffices to account for the difference recorded. On simply heating the semi-coke it gives up as ammonia a further 16% of the nitrogen, reckoned on the original coal, i.e., in all 17.8%. It is concluded that in low-temperature carbonisation a satisfactory yield of ammonia can be obtained only by subjecting the coke to a further heating.—H. J. H.

Bitumen of Bohemian lignite. W. Schneider. Ges. Abhandl. Kemtn. Kohle, 1913, 3, 150–163. Chem. Zentr., 1919, 90, IV., 1072.

Its composition and calorific value, this lignite comes between the German lignites and coal, and it was examined with a view to discovering if other properties, e.g., the quality of the extract obtained under pressure, showed a similar approximation to those of coal. Two Bohemian lignites extracted

with benzene under pressure at 250°–260° C. gave an extract—bitumen B—which approximated to those obtained from German lignites. The portion of this extract soluble in light petroleum spirit was not a viscous oil similar to the corresponding extract from a bituminous coal, but a resinous sticky substance. The results obtained with the bituminous coal are not general, however, for the extract from a long-flaming gas coal was scarcely liquid at room temperature and the portion of it soluble in light petroleum spirit was a syrupy substance which acquired a resinous character.—H. J. H.

Lignite soluble in alkali from the Niederausitz district. W. Schneider and O. Jantsch. Ges. Abhandl. Kemtn. Kohle, 1918, 3, 164–190. Chem. Zentr., 1919, 90, IV., 1072–1073.

A TERTIARY lignite worked near Guben in Eastern Lausitz for use as a pigment and fertiliser was examined and 93–94% of the material dried at 105° C. was found to be soluble in alkali. It consisted mainly of substances resembling humic acid. A portion of the lignite is comparatively rich in bitumen. Soxhlet extraction with benzene yields about 15% of crude montan wax (bitumen A); further extraction under pressure gives 9% of bitumen B. On distilling the lignite in a retort about 16% of tar is obtained. With respect to the production and yield of tar by distillation it resembles the lignites of Saxon-Thüringen, and it is recommended that such treatment should precede the utilisation of the material for colours and as a fertiliser. The humic acids dissolved by 5% ammonia out of the material extracted by benzene under pressure, on dry distillation gave very little tar. The solubility of the humic acids of this lignite was almost the same in solutions of sodium hydroxide, sodium carbonate, and ammonia, whether cold or warm. This does not hold good generally with lignites. The humic acids when heated to 260° C., as in the pressure extraction, are converted into products which are insoluble in cold alkalis, although almost completely dissolved on warming. Where it is desired to retain the humic acids unaltered it is therefore desirable to extract with aqueous ammonia before extraction under pressure. The ammonia solution, however, takes up a portion of both the bitumen A and bitumen B. By a preliminary steaming at 100° C. this can be minimised by rendering the bitumen insoluble in ammonia. Pure montanic acid was practically insoluble in 10 times its weight of 5% aqueous ammonia. From crude montan wax under the same treatment only 0.5% passed into solution.—H. J. H.

Formolite reaction, and interaction of methylal with unsaturated cyclic hydrocarbons. L. G. Radcliffe. Perf. Ess. Oil Rec., 1920, 11, 48–50.

Using the modification devised by Herr (this J., 1910, 1094), with methylal in place of formaldehyde, the author has attempted to correlate formolite numbers (Nastjukoff, this J., 1904, 1082), iodine values, and yields of solid oxidation products (prolonged action of air in presence of metallic catalysts) of mineral oils, but no very characteristic relationships were observed. Qualitatively, the methylal reaction enables 1% of benzol to be detected when mixed with light petroleum spirit. The terpenes and cyclohexane were non-reactive, whilst the xylenes, *p*-cymene, and naphthalene gave the test, which thus appears to be discriminatory for benzenoid hydrocarbons.—A. E. D.

Pyridine from coke-ovens. Dodge and Rhodes. See III.

Gas-fired blast-furnace. Torkar. See X.

PATENTS.

Fuel briquettes; Manufacture of —. H. G. Hills, Bramhall. Eng. Pat. 138,414, 31.1.19. (Appl. 2441/19.) (See also Eng. Pats. 3284 of 1913 and 18,576 of 1914; this J., 1914, 245; 1915, 949.)

ANTHRACITE dust (say 4 parts) is mixed cold with crude coal tar (1 part). The mixture is placed in specially constructed open shallow trays and distilled in an oven, heated externally to a temperature not exceeding 600° C. The briquettes are improved by placing loose weights upon them during the heating.—W. P.

Pulverised fuel; Combustion of solid —. A. Assereto, Savona, Italy. Eng. Pat. 138,502, 23.4.19. (Appl. 10,175/19.)

THE fuel falls directly from the pulveriser into a mixing chamber, where it is mixed with a current of air, which keeps it in suspension. It is withdrawn from here and introduced into the furnace. The feed hopper is thus eliminated and the liability of obstruction lessened.—W. P.

Coke oven with alternative heating arrangement for rich or poor gas; Horizontal regenerative —. H. Engbert, Heerde. Ger. Pat. 312,181, 5.6.18.

THE velocity of the gas and air mixture is increased by reducing the cross-sectional area of the heating flue and lengthening the passage, thereby attaining a rapid and complete combustion and a more favourable heat transmission owing to the higher velocity. The rich or poor gas burners are distributed uniformly over the whole heating surface, whilst air, poor gas, or products of combustion flow through the combustion chambers in a horizontal diagonal direction.—J. F. B.

Distillation residues [coke]; Process for cooling —. E. Zbinden, Zurich. Ger. Pat. 314,661, 2.12.17.

THE hot coke from the carbonising plant is transferred to closed vessels fitted with suitable pipe connections and jackets. Air is drawn through the coke, and thence by an opening to the annular space round the vessel. The air, now hot and containing more or less carbon monoxide and dioxide, is passed on through a jacket surrounding a steam boiler or other waste heat appliance. The air thereby cooled is then returned to the hot coke chambers, circulation being maintained by means of a pump.—H. J. H.

Gas producers. L. Fornas, Paris. Eng. Pat. 123,323, 12.2.19. (Appl. 3431/19.) Int. Conv., 13.2.18.

IN a gas producer of the single or multiple type the feeding tubes are in the form of truncated cones. As combustion progresses the fuel descends from the tubes into a dryer, and thence into the producer chamber. Air is forced downward through the producer from the chamber surrounding the dryer.—W. P.

Gas producer. G. H. Benjamin, New York. U.S. Pat. 1,329,744, 3.2.20. Appl., 19.6.18.

A GAS producer is provided with a tunnel-kiln, and a series of cars for holding the material to be decomposed and progressively moving it through the kiln. A series of grate-bars is carried by each car, with means to cause them to revolve and discharge ash. Gas and air burners, separately controlled, are located on opposite sides of the kiln. The cars are provided with means for supplementing the heat set free from the gas and air burners, and the gaseous body produced is exhausted from the kiln.—B. N.

Gas producer. O. A. Winter, Buxtehude. Ger. Pat. 313,032, 22.6.17.

THE producer, provided with an outlet for producer gas, is fitted with an inner retort through which distillation gases are withdrawn separately. The retort is provided with holes in the walls and is rotated. Within the retort is a core for distributing the bituminous fuel. By the rotation of the retort the distillation gases are forced continuously to find new paths through the pasty mass of bituminous fuel.—J. F. B.

Gases; Apparatus for cooling and scrubbing —. A. M. Hunt, Berkeley, and D. E. Fogg, Oakland, Cal. U.S. Pat. 1,327,599, 6.1.20. Appl., 25.5.14.

A TOWER has a gas inlet at one side above the bottom and a gas outlet at the top; banks of cooling coils are situated in the tower above and below the gas inlet; means are provided for spraying a liquid on the pipes in a counter direction to the currents of gases; the cooling pipes are connected with a header in the tower, and means are provided for maintaining a constant circulation, with intermittent cooling, of a second liquid, through the header and pipes.—J. F. B.

Hydrocarbon and other compounds; Apparatus for the electro-chemical treatment of liquid —. L. B. Cherry, Kansas City, Mo. U.S. Pat. 1,327,023, 6.1.20. Appl., 26.2.16.

A LIQUID hydrocarbon compound is treated by introducing a gas carrying hydrogen and vaporising the liquid. Means are provided for treating the mixture of vapour and gas electrically, so as to produce a compound of different gravity from that of the original liquid, and the mixture is heated whilst being treated.—B. N.

Gasoline from natural gases; Apparatus for recovering —. A. B. Cross, Denver, Colo. U.S. Pat. 1,327,906, 13.1.20. Appl., 5.3.18.

A CYLINDRICAL receiver is surrounded by a jacket, caps being provided on the ends of the jacket, and having packing boxes through which the ends of the receiver pass; a pipe on one end of the receiver is connected to a gas supply. The opposite end of the receiver is connected by a pipe to the inlet of a pressure regulator, and the outlet of the pressure regulator is connected to one end of the jacket. An outlet pipe extends from the opposite end portion of the jacket, a drain pipe connects the jacket with a tank, and another drain pipe connects the receiver near its outlet end with the tank.—J. F. B.

Hydrocarbons; Process of treating —. B. Andrews, Houston, Tex., and W. C. Averill, jun., Meraux, La. U.S. Pat. 1,329,739, 3.2.20. Appl., 19.9.18.

HYDROCARBON oil is injected into tubes containing melted metal, and the resulting vapours and melted metal are circulated through the tubes, the hydrocarbon vapours being then withdrawn.—B. N.

Sulphonic acids; Process of recovering — from mineral-oil sludge. R. E. Divine, Assignor to The Twitchell Process Co., Cincinnati, Ohio. U.S. Pat. 1,330,624, 10.2.20. Appl., 24.6.18.

A NEARLY colourless alkaline-earth sulphonate is prepared from the sludge formed by sulphonating a portion of a mineral oil distillate by mixing the sludge with water, separating free oil, neutralising the solution with an alkaline earth, and salting out the sulphonates from the solution with a soluble salt of the same alkaline earth.—L. A. C.

Petroleum, tar, and the like; Preheater for use in the distillation of —. L. Steinschneider, Brünn, Austria. U.S. Pat. 1,302,988, 6.5.19. Appl., 17.9.13.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Arc lamps; New cadmium vapour —. F. Bates. Phil. Mag., 1920, 39, 353—358.

AN inverted U-tube of 10 c.c. capacity is fitted at its lower ends with two long quartz capillaries by means of which tungsten wire electrodes are admitted. The electrodes are fastened into the capillaries by lead seals. The lamp is filled by distilling (at 0.001 mm. pressure), from a quartz bulb attached at the bend of the U-tube, a gallium-cadmium alloy containing 2—3% of gallium. The presence of the gallium renders the cadmium soft and so prevents the breakage of the lamp when the metal solidifies. When sufficient metal has been distilled over the lamp is sealed off. The lamp will burn with 3 amps. at 110 volts with a drop of 14 volts across the terminals, but is more efficient with a current of 7 amps. and a drop of 25 volts. To start the lamp one limb must be heated with a Bunsen flame. The light is that of almost pure cadmium vapour, and the lamp furnishes a source of monochromatic red light of wave length $\lambda 6439 \text{ A.}$ —J. F. S.

Acetyl content of wood. Pringsheim and Magnus. See V.

PATENTS.

Destructive distillation of wood; Process for recovering oils through the —. D. L. Hanson, Wilmington, N.C., Assignor to Pine Nene Products Co., Jacksonville, N.C. U.S. Pat. 1,330,632, 10.2.20. Appl., 7.2.19.

To prevent decomposition of the gases and vapours from the destructive distillation of wood they are continuously removed by the combined action of a vacuum pull towards the retort outlet and the pressure of an oxidising agent introduced at a point remote from the outlet.—W. P.

Arc lamp carbons, especially for searchlights. Allgem. Elektrizitäts-Ges., Berlin. Ger. Pat. 307,073, 6.11.17.

THE carbons consists of an inner cylindrical part over which is drawn an outer tubular part, either or both of which are provided with longitudinal grooves, which are partly or wholly coppered. The molten copper, as long as it is not vaporized by the arc, flows along the grooves.—A. R. P.

Graphite electrode, specially suitable for searchlights. C. Conradty, Nürnberg. Ger. Pat. 310,603, 25.9.18.

THE electrode consists of flake graphite bound with tar or other suitable organic bond which, on heating in the electric furnace, changes to graphite.

The flakes are so arranged that they lie in the direction of the current.—A. R. P.

Decolorising carbon. U.S. Pat. 1,327,222. See XVII.

III.—TAR AND TAR PRODUCTS.

Phenols; Hydrolysis of phenoxycetic acid with alkali and preparation of pure —. F. Fischer and W. Glund. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 75—81. Chem. Zentr., 1919, 90, IV., 1052.

IN order to identify the individual phenols of low-temperature tar separated as phenoxycetic acids (cf. Glund and Breuer, this J., 1920, 151 A), it was necessary to recover therefrom the free phenols in satisfactory yields. Acids proved ineffective. By the action of 4 mols. of potassium hydroxide on 1 mol. of the phenol derivative at about 275° C. almost pure phenol was obtained with a 50—75% yield. For each phenol the optimum reaction temperature must be determined by trial. A tightly closed, and continuously shaken, electrically heated Mannesmann tube was used as autoclave. The results are tabulated to show the yield of pure phenol set free, and the proportion remaining as acetyl derivative; the difference between the sum of these and 100 gives the loss on working:—

Acid.	Temp.	Mols. KOH.	Free phenol.	Combined phenol.
Phenoxycetic acid ..	250° ..	4 ..	52.1 ..	14.5 ..
..	300° ..	3 ..	57.0 ..	— ..
o-Cresoxycetic acid ..	275° ..	4 ..	73.2 ..	2.5 ..
p-Cresoxycetic acid ..	275° ..	4 ..	72.2 ..	9.0 ..
Thymoxycetic acid ..	275° ..	4 ..	48.5 ..	46.2 ..

—H. J. II.

Phenol; Determination of small quantities of — in mixtures of phenols. F. Fischer and P. K. Breuer. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 82—88. Chem. Zentr., 1919, 90, IV., 1032.

THE method is based on a suggestion of Müller (Lunge-Köhler, 1912, p. 762) that when homologous phenols are fractionally precipitated by a restricted amount of hydrochloric acid, ordinary phenol is precipitated last in a relatively pure condition. Thus 10 grms. of pure phenol was dissolved in 90 grms. of mixed cresols (b. pt. 200°—202° C.) from a low-temperature tar and 192 c.c. of 5N sodium hydroxide was added. This solution was extracted twelve times with 157 c.c. of 5N hydrochloric acid, followed by vigorous shaking with 150 c.c. of ether for 15 minutes and, after separating the ether layer, with a further 100 c.c. of ether, the last extraction being made after the addition of salt. The united ether extracts were evaporated at the ordinary temperature to avoid loss of phenol. The eleventh acid extract gave 7 grms. of crystallisable phenol, and from the sixth and succeeding extracts was recovered altogether 92% of the phenol taken, in the form of a mixture with cresol melting at 26° C.—H. J. II.

Phenol content of low-temperature tar and over-heated tars. F. Fischer and P. K. Breuer. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 89—97. Chem. Zentr., 1919, 90, IV., 1070—1071.

THE low-temperature tar from coal contains only about 0.06% of phenol. Normal coal tar results from the cracking of low-temperature tar at 700°—750° C. and contains about 1% of phenol. It is possible that a considerably higher percentage than this could be realised. By the improved analytical methods described (Fischer and Breuer, preceding) a producer low-temperature tar was shown to contain 0.21% of phenol. The total phenol fraction from a large quantity of this tar was cracked at 700°—750° C., and the phenol content was thereby

doubled, presumably by degradation of the higher phenols. As the quantity of tar was thereby halved, the concentration of the phenol was increased fourfold, i.e., to 0.97%. The original producer tar from a long-flame gas coal from the Saar field contained more phenol than coke-oven tar from the Ruhr field. Lohberg coal distilled in the revolving retort (this J., 1919, 563A) gave a tar containing only 0.06% phenol.—H. J. H.

Low-temperature coal tar; Suitability of — for the production of coumarone-resin. W. Gluud and P. K. Breuer. Ges. Abhandl. Kennt. Kohle, 1919, 3, 238—242. Chem. Zentr., 1919, 90, IV., 1071.

If the fraction 155°—185° C. of low-temperature tar is shaken with strong sulphuric acid, a dark brown soft product is obtained amounting to 0.05% of the tar. Thus the ordinary process does not lead to the formation of coumarone-resins. If, however, the phenols are cracked by heating to a suitable temperature and the appropriate fraction is collected, a typical yellow hard coumarone-resin is subsequently obtained. Apparently the coumarone-resins are produced by substances which originate by the cracking of the phenols in low-temperature tar.—H. J. H.

Distillation; Brown's formula for [fractional] — [applied to benzene-toluene mixtures]. S. Young. Sci. Proc. Roy. Dublin Soc., 1920, 15, 667—672.

BROWN'S formula $M'_A/M'_B = C M_A/M_B$ (where M'_A , M'_B and M_A and M_B are the relative numbers of molecules of A and B in the vapour and liquid respectively, and C is a constant depending on the relative vapour pressures of the pure substances at the boiling point of the mixture; Chem. Soc. Trans., 1879, 547; 1880, 49; 1881, 304, 517) is applicable without serious error to mixtures of benzene and toluene, of which the vapour pressure P approximately equals $MP_A + (1-M)P_B$, P_A and P_B being the vapour pressures of the two pure substances at the same temperature, and M the molar fraction of the substance A. Further, for benzene and toluene the best value of the constant C differs but slightly from the ratio P_A/P_B , viz., 2.591.

—G. F. M.

Pyridine; Recovery of — from by-product coke-ovens. F. E. Dodge and F. H. Rhodes. Amer. Inst. Chem. Eng., Dec., 1919. Chem. and Met. Eng., 1920, 22, 274—275.

THE quantity of pyridine bases passing the tar separators amounts to about 1 lb. per ton of coal coked, and these bases are absorbed by the acid solution in the ammonia saturation plant. No pyridine sulphate was found in the ammonium sulphate crystals when the mother liquor contained 2.5% pyridine. If the mother liquor is neutralised by bubbling through it a gas rich in ammonia, the heat generated by the reaction is sufficient to raise the solution to its boiling point and to distil off the liberated pyridine bases. In a plant designed for the recovery of pyridine, the acid mother liquor, saturated with pyridine salts, is treated with ammonia from an ammonia still. Vaporised pyridine passes through a condenser system to receivers, and the residual liquor in the still is acidified before returning it to the ammonium sulphate plant. The condensed pyridine bases are separated from the accompanying water by the addition of solid ammonium sulphate, the dense solution of ammonium sulphate then being drawn off.—C. A. K.

Formolite reaction. Radcliffe. See IIA.

Cresols and cresol-soap substitutes. Hailer. See XIXb.

PATENTS.

Tar oils for Diesel engines; Process for improving —. F. Raschig, Ludwigshafen. Ger. Pat. 315,030, 27.4.15.

THE tar oil is shaken with a suitable quantity of water and the aqueous layer is separated. The latter removes mainly substances containing chlorine, which owing to corrosive action on the oil-inlet valves render the tar oil unsuitable for Diesel engines.—H. J. H.

Chlorobenzol; Method of nitrating —. R. Heyder, Forest Hills, N.Y., Assignor to Williamsburg Chemical Co., Inc., Brooklyn, N.Y. U.S. Pat. 1,330,074, 10.2.20. Appl., 26.4.18.

CHLOROBENZOL is treated with a nitrating agent, and the mixture is maintained below about 65° C. during the greater part of the time necessary to complete the reaction.—L. A. C.

Farnish from indene. Ger. Pat. 310,783. See XIII.

IV.—COLOURING MATTERS AND DYES.

Butyl alcohol; Use of — as a solvent for anthocyanins. O. Rosenheim. Biochem. J., 1920, 14, 73—74.

BUTYL alcohol dissolves anthocyanins much more readily than does amyl alcohol. It is therefore the best solvent from which to isolate these substances in the pure condition. (See also J. Chem. Soc., April, 1920.)—J. F. S.

Glyoxal from acetylene. Wohl and Bräunig. See XX.

PATENT.

Azo-dyestuffs; Manufacture of — and intermediate products therefor. O. Imray, London. From Soc. of Chem. Ind. in Basle, Switzerland. Eng. Pat. 137,733, 12.5.19. (Appl. 11,891/19.)

α -HYDROXYNAPHTHALENESULPHOCARBOXYLIC acids are obtained from naphthalenedisulphocarboxylic acids by partial fusion with 40% sodium hydroxide for 3—4 hours at 195° C. under pressure in an autoclave, and precipitation from the reaction mixture with hydrochloric acid. Mordant-dyeing azo dyestuffs are produced from these acids by coupling with aromatic o-hydroxydiazocompounds, or preferably their o-carboxylic acids, i.e., o-diazo derivatives of salicylic acid. Coupling is effected by mixing equimolecular proportions of a solution of the diazonium compound with a concentrated solution of the mono-sodium salt of the α -hydroxynaphthalenesulphocarboxylic acid containing 2 mols. of sodium hydroxide and about 4 mols. of anhydrous sodium carbonate. The precipitation of the dye is complete in about 12 hours. Examples are given of the coupling of 4-nitro-2-diazo-1-hydroxybenzene-6-carboxylic acid and 1-hydroxynaphthalene-3-sulpho-6-carboxylic acid to an azo-dye giving on wool in an acid bath red shades which when after-chromed change to a bordeaux fast to fulling and potting. In chrome printing on cotton it yields a bordeaux fast to soap, chlorine, and light. 4-Sulpho-2-diazo-1-hydroxybenzene-6-carboxylic acid couples with either 1-hydroxynaphthalene-3-sulpho-5-carboxylic acid or -6-carboxylic acid to give a red wool dye which on after-chroming becomes red-violet and gives a fast red-violet in chrome printing on cotton. The analogous 4-chlorodiazohydroxybenzenecarboxylic acid gives on coupling a red dye becoming a fast violet on after-chroming or in chrome printing on cotton.—G. F. M.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; Deterioration of — on wet storage. N. Fleming and A. C. Thaysen. *Biochem. J.*, 1920, 14, 25—28.

DETERIORATION of damp cotton is brought about by a *streptothrix* and by a *schizomycete*, both of which cause a breaking down of the cuticle. Deterioration is retarded if the moisture content of the cotton falls below 9%. The amount of deteriorated cotton may be estimated microscopically by counting the fibres after the sample has been treated by Ball's viscose process.—J. F. S.

Broom; Treatment of — with alkali for the production of fibres suitable for spinning. H. Kämpf. *Mitt. Deuts. Forschungsinst. Textilstoffe*, 1918, 255—300. *Chem. Zentr.*, 1919, 90, IV., 1062.

DIGESTION with alkali alone does not give a satisfactory product while retting alone does not suffice for the isolation of the fibres. If carried too far the latter causes partial attack of the fibre itself. A combination of the two processes, retting followed by treatment with alkali, gave a pure, almost colourless, strong but soft fibre, which can be used as substitute for more costly materials. The retting is best prolonged over several days until the bast is readily loosened. Afterwards the material is treated with 0.5—1% caustic soda solution for 2—3 hours at ordinary pressure or 2 atm. pressure. The hydrochloric acid furfural reaction affords a method of control. The pentosan number is connected in certain cases with the tensile strength of the product.—H. J. H.

Wood; Acetyl content of —. H. Pringsheim and H. Magnus. *Z. angew. Chem.*, 1920, 33, 56.

THE authors reply to a criticism by Schwalbe and Becker (this J., 1920, 185 A) of their previous communication in regard to the respective amounts of acetic acid obtained from pine woods and wood from deciduous trees. Beechwood lignin contains 37.8% acetyl as against 19.85% in pine wood lignin. Boiling the wood for 3 hours with 2.5% sulphuric acid is not sufficient to extract all the acetic acid. It is necessary to treat the wood for 6 hours with eight times its quantity of 3.5% sodium hydroxide under a pressure of 6 atms.—W. J. W.

Cotton hull fibre for pulp; Cooking —. O. Kress. *Paper*, 1920, 25, 961—968, 1009—1011. (See also this J., 1919, 858 A.)

EXPERIMENTS were carried out on the large scale on the digestion of cotton hull fibre in plant employed for the manufacture of soda wood pulp. On account of the spongy nature of the material the circulation of the liquor had to be assisted by an external auxiliary pump and a somewhat high ratio of liquor to fibre (7:1) had to be employed. A maximum steam pressure of 80—85 lb. per sq. in. was used; with 45 lb. steam pressure the disintegration of the hull particles was far from satisfactory. Owing to the high liquor ratio the proportion of caustic soda (3% concentration) used was somewhat excessive, viz., 21—21% of the weight of the charge. The maximum pressure was reached in 4 hours and the digester was kept under 80—85 lb. pressure for a further 4 hours. The dry nature of the stuff caused considerable difficulty in blowing out the charge after digestion in the manner used for wood pulp. The ordinary treatment of soda wood pulp after washing in the diffusers is not suitable for cotton hull pulp owing to the length and "freeness" of the fibre. The hydration of the cellulose is developed with considerable difficulty, and the best results would probably be

obtained by starting the beating treatment before the washing of the pulp was complete, so that the roll of the washing engine would brush the fibre with considerable pressure while still in the alkaline condition. The removal of the cellular residues of the disintegrated hulls during washing is desirable for the manufacture of strong papers; it is, however, more rational to remove the hull particles themselves as completely as possible by suitable mechanical treatment of the raw fibre before digestion. The paper produced is not so strong as that produced from hard rag stock, but resembles paper from soft "seconds" or "thirds" rags; this, however, is largely a matter of the development of hydration, and the fibre calls for a heavier crushing treatment in the beater without undue reduction in length. The stock is cleaner than that prepared from munition linters, being freer from extraneous dirt; with suitable digestion no difficulty is experienced in bleaching economically to a good white colour.—J. F. B.

Turbidimeter for cellulose. Sheppard. *See* XXIII.

PATENTS.

[*Fabric*] *articles; Process and apparatus for drying —.* D. K. Tullis, Clydebank. Eng. Pat. 137,427, 12.3.19. (Appl. 6175/19.)

THE fabric articles are placed on a travelling apron which carries them round a heated roller in order to preheat them and then transfers them to a closed drying chamber through which they are led, exposed to hot air currents, in a zig-zag course by means of tapes in such a manner that the exposed surfaces are repeatedly changed by reversing the goods each time they pass from one set of tapes to another. Inside the drying chamber a number of pairs of superposed rollers are arranged in stepped relationship and tapes are wrapped around the pairs of rollers, the tapes wrapped round one pair of rollers being staggered in relation to the tapes wrapped round the pair of rollers immediately beneath.—J. F. B.

Fabric; Process of treating — [with lubricant]. W. C. Carter, Radnor, Ohio, Assignor to The Goodyear Tire and Rubber Co., Akron, Ohio. U.S. Pat. 1,327,904, 13.1.20. Appl., 19.10.16.

YARN or fabric is bathed in a hot vapour and a relatively cold body of liquid carrying the lubricant in suspension is then brought in contact with the yarn or fabric, whereby the vacuum formed by condensation of the vapour causes impregnation of the material.—J. F. B.

Vegetable proteins; Product derived from — [for manufacture of artificial silk, films, etc.]. Z. Ostenberg, San Jose, Cal. U.S. Pat. 1,316,854, 23.9.19. Appl., 12.2.17.

A NON-THERMOPLASTIC material suitable for the manufacture of artificial silk, films, etc., is composed of a mixture of a vegetable prolamine, i.e., a plant protein soluble in 70% alcohol (e.g., gliadin, zein) and a small quantity of a toughening agent (fat, wax, resin, soap, sulphonated oil, sugar, glycerin, phenols, terpenes, etc.). The product may be rendered resistant to water by treatment with formaldehyde or the like.

Yarn windings, particularly paper yarn; Apparatus for drying —. E. Jagenberg, Düsseldorf, Germany. U.S. Pat. 1,330,025, 3.2.20. Appl., 9.5.17.

YARN windings, such as paper yarn on cops, crossed reels, and the like, are dried in an apparatus comprising an air-tight casing, means for producing a current of air through the casing, nozzles on the casing which lead the air current through the cops or cross reels, and means for heating the

air current. Valves are fitted over the nozzles, and are opened by means of stems when reels are fitted on to the nozzles.—J. F. B.

Pulp; Method of preparing —. C. Bache-Wüg, Portland, Me. U.S. Pat. 1,327,221, 6.1.20. Appl., 20.2.19.

CELLULOSIC material is treated with sodium chloride and the mass is subsequently cooked with bisulphite liquor until the ligneous matter has been separated from the fibre.—J. F. B.

Rotary digesters and like boilers. K. Hellner, Falun, Sweden. Eng. Pat. 137,742, 28.5.19. (Appl. 13,436/19.)

IN rotary digesters for the manufacture of cellulose and the like the liquor is heated with indirect steam in order to avoid dilution by condensed water. Heating elements are provided outside the digester in such a manner that they take part in its rotation and are connected with the inside of the digester in such a manner that the liquor can pass constantly through the heating elements and be heated by means of steam pipes located therein, the supply of steam being passed through one trunnion of the digester, while the condensed water is discharged through the other.—J. F. B.

Fireproof [pyroxylin] composition. J. C. Emhardt, Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,329,386, 3.2.20. Appl., 25.2.18.

A COMPOSITION containing pyroxylin and ammonium magnesium phosphate.—J. F. B.

Cellulose esters; Process for softening —. F. Redlich, Zehlendorf-Mitte. Ger. Pat. 304,224, 14.2.17.

CELLULOSE esters are incorporated with the neutral ester of a di- or poly-basic organic acid of the aliphatic or aromatic series with the aid of a volatile solvent. Resins, fats, and oil may also be incorporated by dissolving them in the neutral ester or in the volatile solvent. For example, 12 kilos. of cellulose acetate is mixed with 10 kilos. of diethyl tartrate.—A. R. P.

Paper; Process of re-pulping old or waste —. J. M. Burby, Webster, Mass. U.S. Pat. 1,327,590, 6.1.20. Appl., 14.4.16.

OLD paper made from mechanical wood pulp is converted into chemical wood pulp by boiling the paper in a solution of chemicals adapted to convert the woody fibre into cellulose.—J. F. B.

Carbon-paper and ink composition therefor. H. Ohashi, New York, N.Y.; M. V. Ohashi, administratrix. U.S. Pat. 1,328,188, 13.1.20. Appl., 5.12.16.

PAPER is treated with ink prepared with the reaction products of an aniline dye soluble in water, calcium chloride, an emulsifying agent, and an emulsifiable substance.—J. F. B.

Paper; Apparatus for making ornamental —. E. Mahler, Assignor to Kimberly Clark Co., Neenah, Wis. U.S. Pat. 1,329,130, 27.1.20. Appl., 7.9.17.

A FOURDRINIER wire is arranged to move in a straight line free from lateral shake while the paper is being formed on the wire, thereby causing the formation of depressions and elevations in the paper web. Liquid colour is sprayed by means of a gas under pressure on to the upper surface of the wet plastic web of paper moving with the wire, the spray impinging on the paper at an acute angle to the horizontal.—J. F. B.

Paper and pasteboard pulp; Process for engine-sizing of —. Zellkoll Ges. m. b. H., Cologne-Rodenkirchen. Ger. Pat. 303,828, 11.8.16.

THE sizing agent is an easily dissociated organic salt of aluminium such as the acetate or formate, which may be obtained by the interaction of aluminium sulphate or alum and an easily obtainable salt of the organic acid, such as the barium salt. The use of soap or resins in addition is not necessary.—B. V. S.

Safety paper. E. Haussmann, Berlin. Ger. Pat. 303,989, 6.3.17.

A COMPOSITE paper has a middle sheet uniformly coloured with an easily reacting colouring matter, and on either side of this one or more covering films of a thin absorbent paper, only slightly coloured if at all. The colouring matter of the inner sheet is destroyed if the outer surface is attacked by chemical means, and the inner sheet is soon exposed to view by abrasion.—B. V. S.

Size for paper; Production of —. A. Mitscherlich, Freiburg. Ger. Pat. 314,652, 22.9.15.

TANNERY glue is treated with waterglass and the dark-coloured substance which is deposited after some time is separated. The purified clear liquid is added to the paper pulp in the hollander.—H. J. H.

Paper-making machines; Press-roll arrangement for —. J. K. Darby, Chillicothe, Ohio. U.S. Pat. 1,327,225, 6.1.20. Appl., 7.6.16.

Paper-making machine. N. J. Nicks, Kalamazoo, Mich. U.S. Pat. 1,327,289, 6.1.20. Appl., 3.9.18.

Lanolin. U.S. Pat. 1,330,210. See XII.

Tanning material. Ger. Pat. 304,349. See XV.

Films or filaments. Eng. Pat. 138,379. See XXI.

PATENTS.

Finishing and waterproofing textile fabrics; Process for —. E. Naefe, Berlin-Britz. Ger. Pat. 314,969, 9.12.15.

THE fabric is treated in a solution of the sodium ammonium salt of alginic acid, and is then passed through a bath of zinc sulphate or similar heavy metal salt. The insoluble salt of alginic acid produced separates in a colloidal form giving a waterproof finish which resists a boiling neutral dye-bath.—H. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Ammonia; Catalytic oxidation of —. B. Neumann and H. Rose. Z. angew. Chem., 1920, 33, 41—44, 45—48, 51—55.

THE authors give an extensive survey of the numerous processes and researches in connection with the catalytic oxidation of ammonia and contribute some results of their own investigations. Special attention has been directed to the influence of the ammonia concentration, the velocity of the gas stream, the temperature, and of various catalysts including platinum, metallic oxides, and mixtures of the latter. The highest yields are obtainable with platinum at 500° C. (96%); ferric

oxide at 670° C. (90%); and iron/bismuth oxide at 600° C. (95%). From curves plotted to show the gas composition at approximately 300°–700° C. with the above catalysts, it is apparent that, under fixed conditions, the oxidation will proceed continuously without extraneous heat. With platinum gauze of 3000 meshes per sq. cm. as catalyst, the best yield (96%) was obtained with a velocity of gas current of 20 litres per hour and the yield was not greatly affected by increase of the ammonia concentration from about 3 to 9% by vol. With ferric oxide the best velocity was about 22 litres per hour (about 90% yield).—W. J. W.

Acid industry; [Use of] Raschig's rings in —.

H. Schellhaass. Chem.-Zeit., 1920, 44, 122–123.

ATTENTION is directed to the advantages attained by the use of Raschig's rings as a filling material for absorption towers in the manufacture of sulphuric acid, nitric acid, hydrochloric acid, etc. The rings are made of earthenware in various sizes, usually 120 mm. in height and 100 mm. in diameter (external), the thickness of the wall being about 10 mm.—W. P. S.

Sulphur; Production of — [from gypsum] in Germany. O. F. Kaselitz. Z. angew. Chem., 1920, 33, 49–51.

ONE of the processes developed in Germany during the war to produce the sulphur required for sulphuric and sulphurous acid manufacture consisted in reducing gypsum with coke, and converting the resultant sulphur dioxide into trioxide by a contact process. Cement is manufactured from the by-products. For the production of sulphur gypsum is heated with coke or coal in a rotary furnace to 1100° C., and the calcium sulphide is treated with steam to form hydrogen sulphide, which is finally oxidised in a contact furnace. The purity of the product is 99.95%.—W. J. W.

Ammonia-ammonium thiocyanate; Equilibrium in the system —. H. W. Foote and M. A. Hunter. J. Amer. Chem. Soc., 1920, 42, 69–78.

SOLUTIONS of ammonia saturated with ammonium thiocyanate (prepared from dry ammonia gas and solid ammonium thiocyanate) have the following vapour pressures: –78° C., 1 mm.; –65°, 4 mm.; –50°, 9 mm.; –34°, 21 mm.; –23°, 34 mm.; –20°, 41 mm.; 0°, 107 mm., and +20° C., 225 mm. Saturated solutions of ammonium thiocyanate in ammonia contain the following amounts of ammonia; at 0° C., 23.3; 10°, 22.65; 20°, 21.6; 30°, 20.15; 40°, 18.4; and at 50° C., 16.65%. The practical application of ammonium thiocyanate as a commercial absorbent for ammonia is discussed. It could be used in cases where it is necessary to eliminate water. For example, from the equilibrium mixture of nitrogen, hydrogen, and ammonia, produced in the synthesis of ammonia, the use of ammonium thiocyanate would permit of the recovery of 98.1% of the ammonia at –20° C., 98.9% at –30°, and 99.6% at –50° C. (See also J. Chem. Soc., Apr., 1920).—J. F. S.

Equilibria in solutions containing mixtures of salts. II. The system water and the chlorides and sulphates of sodium and magnesium at 25° C. W. C. Blasdale. J. Ind. Eng. Chem., 1920, 12, 164–167.

PREVIOUS work on this subject (*cf.* Hildebrand, this J., 1918, 180 A) indicates that the solid phases to be expected at 25° C. are $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$, $\text{MgSO}_4 \cdot \text{H}_2\text{O}$, $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, Na_2SO_4 , $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, NaCl , and $\text{MgSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ (astrakanite). Experiments were made to ascertain the limits of the fields representing the composition of all the solutions which can be in equilibrium with each of the eight solid phases. The results are shown in a curve in which the horizontal axis is used to represent the number of mols. of MgSO_4

and NaCl , and the vertical axis the number of mols. of MgCl_2 and Na_2SO_4 , per 1000 mols. of water. The compositions of the solutions which represent critical points are given in the following table:—

Composition (grms. per 100 grms. of water) of solutions saturated at 25° C.

Saturated with:	MgSO_4	Na_2SO_4	NaCl	MgCl_2
$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	36.39	—	—	—
$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	—	27.94	—	—
NaCl	—	—	35.63	—
$\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$	—	—	—	54.97
$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ and astrakanite	32.07	19.68	—	—
$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ & astrakanite	25.36	27.09	—	—
$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ and Na_2SO_4	—	21.68	18.82	—
Na_2SO_4 and NaCl	—	9.81	32.16	—
MgCl_2 and $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$	—	—	—	54.87
$\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ & $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$	3.61	—	—	54.01
$\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$ & $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	6.37	—	—	49.74
$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$, Na_2SO_4 , and astrakanite	7.71	18.67	15.50	—
Na_2SO_4 , NaCl , & astrakanite	12.59	1.01	29.67	—
$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$, and astrakanite	12.03	—	9.79	20.47
$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$, and NaCl	6.53	—	2.20	39.94
$\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$, NaCl , and $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$	2.53	—	0.18	53.88

—S. S. A.

Cyanide; A new —. [Calcium cyanide, from calcium cyanamide.] W. S. Landis. Amer. Electrochem. Soc., Jan., 1920. Chem. and Met. Eng., 1920, 22, 265–268.

THE conversion of calcium cyanamide into calcium cyanide by fusion with sodium chloride was first attempted in a resistance furnace of the tilting type. Calcium cyanamide was fed by hand into a bath of molten sodium chloride, and the molten charge was tapped off and cooled. Considerable difficulty was experienced by the increase in conductivity of the magnesite brick lining of the furnace due to the reduction of the iron content to the metallic state by the cyanide. The excessive foaming produced on the addition of calcium cyanamide was controlled by adding a small quantity of calcium carbide. It was not found necessary to keep the reaction temperature below 960° C. as in previous German practice. Later developments included the use of a single-phase furnace with conducting hearth and a single suspended electrode, together with a considerable reduction in the quantity of salt used. A large furnace has been successfully operated with a charge consisting of two parts of calcium cyanamide to somewhat less than one part of salt. A product containing as high as 50% equivalent sodium cyanide has been obtained, and the cyanogen content has been proved in practice relatively as efficient in the extraction of precious metals as that of 98% sodium cyanide, the cost of production of which is considerably higher. Analysis indicates that the product is a mixture of calcium cyanide, sodium chloride, and free lime.

—C. A. K.

Sodium fluoride; Case of poisoning by —. O. Vallée. J. Pharm. Chim., 1920, 21, 5–8.

SEVERAL persons suffered severe illness after eating pancakes in the preparation of which, as was discovered subsequently, sodium fluoride had been used accidentally in place of sodium bicarbonate. The amount of sodium fluoride taken was, in most cases, about 0.228 gm.—W. P. S.

Hydrogen and oxygen mixtures; Catalysis of — at the ordinary temperature by moistened contact substances.—II. Platinum metals as hydrogen carriers. K. A. Hofmann and L. Zipfel. Ber., 1920, 35, 298–314. (Compare this J., 1917, 136.)

MIXTURES of oxygen and hydrogen are catalysed

at palladium, platinum, or iridium surfaces at very different rates, depending on the condition of the metal with regard to its gas charge. Pre-treatment with oxygen is 30–50 times as effective in the case of palladium, 3 times with platinum, and 3–10 times with iridium as is pre-treatment with hydrogen. The greater activity caused by charging with oxygen is not due to the adsorbed or occluded gas serving as a source for the formation of water, since the amount of metal required for catalysis is insufficient to produce this effect, but depends on the production of a "fresh" hydrogen-metal combination, which, in the cases of palladium and platinum, is far more active than an "aged" preparation. The catalyst shows greater activity in proportion as this "fresh" condition is more rapidly and completely developed. In the case of iridium another factor is involved, since the metal, in presence of gases containing excess of oxygen, can function as an active oxygen electrode. The close parallelism between catalytic and electromotive activity indicates that both effects are to be ascribed to the same cause. This probably depends on the presence of free or metallically-combined hydrogen atoms, which cause the hydrogen potential and ultimately combine with the oxygen of the gas mixture to form water. Under the experimental conditions adopted an active oxygen electrode is only formed with finely-divided iridium when the oxygen concentration is high; platinum and palladium behave entirely as hydrogen electrodes. The maximum velocity of formation of water is not invariably observed when the gases are used in the proportion of 2 vols. of hydrogen to 1 vol. of oxygen, but, according to conditions, may occur at a greater or smaller oxygen concentration according as the catalyst becomes more or less readily saturated with hydrogen. If the catalyst can also function as an oxygen electrode, as in the case of finely-divided iridium, a second maximum may occur at a higher oxygen-content of the gas. It may be stated generally that the surface does not show its greatest catalytic activity when hydrogen and oxygen are absorbed according to the measure of their combination at an electrically-neutral electrode, but that the maximum possible hydrogen or oxygen potential must be "freshly" developed in order to react with the gaseous mixture at the maximum rate.—H. W.

PATENTS.

Sulphuric acid; Process for the preparation of — from naturally occurring sulphates. B. Dirks, Hemelingen. Ger. Pat. 301,791, 24.3.17.

NATIVE sulphates, such as gypsum or anhydrite, are transformed by known methods into ammonium sulphate, which is mixed with metallic oxides, especially iron oxide or hydroxide (*e.g.*, limonite), and the mixture slowly heated to 250° C. until the ammonia is expelled. On further heating to redness, sulphur trioxide is evolved in almost quantitative yield. The residue of iron oxide is moistened with water and used again in the process. Substitution of alumina or chromic oxide for iron oxide does not give such good results; manganese, nickel, and cobalt oxides give quantitative yields, but their sulphates are more difficult to decompose.—A. R. P.

Synthetic ammonia; Transformation of — into a transportable product directly utilisable for agriculture in conjunction with the production of sodium carbonate. L'Air Liquide Soc. Anon. pour L'Etude et L'Exploit. des. Proc. G. Claude, Paris. Eng. Pat. 131,870, 14.3.19. (Appl. 6448/19.) Int. Conv., 24.8.18.

The process described in Eng. Pat. 130,365 (this J., 1919, 690 A) is improved by adding to the liquid

from which sodium bicarbonate has been precipitated, sea salt, ammonia, and carbon dioxide, the sea salt being added in such limited quantities that it remains dissolved throughout the operations, and so does not mix with the ammonium chloride. The solution is cooled to 0°–5° C.; the ammonium chloride precipitated is separated, centrifuged, and heated to about 70° C. to destroy alkalinity. The remaining liquor is treated with sea salt and carbon dioxide, thereby precipitating sodium bicarbonate and forming a fresh ammonium chloride liquor. For the production of the low temperature required, liquid ammonia is evaporated in a coil in direct contact with the ammonium chloride to be cooled, and the resulting gaseous ammonia is passed into cooled brine contained in the dissolving and carbonating tank. The expansion of the ammonia with external work may be utilised for the production of additional cooling effect, and the evaporation of liquid or solid carbon dioxide may also be utilised for cooling purposes.—S. S. A.

Ammonium nitrate; Manufacture of —. J. R. Partington, Lostock Gralam, and G. J. Jones, London. Eng. Pat. 134,562, 1.2.18. (Appl. 1874/13.)

AMMONIUM nitrate, produced in the form of a mist by the interaction of ammonia gas and nitric acid or by other means, is caused to pass through a dehydrating agent, such as sulphuric acid, and can then be readily condensed and collected. Very little mist is absorbed by the sulphuric acid.

—W. J. W.

Ammonium nitrate; Production of —. J. R. Partington, G. J. Jones, and T. K. Brownson, London. Eng. Pat. 136,190, 4.3.18. (Appl. 3792, 18.)

AMMONIUM nitrate is manufactured by bringing together oxides of nitrogen, oxygen, water, and ammonia in such proportions that the oxygen is in excess of the theoretical quantity required to convert the oxides of nitrogen into nitrogen peroxide, the ammonia is insufficient to react with the whole of the oxides of nitrogen, and the water does not exceed the amount necessary to convert all the ammonia into ammonium nitrate by interaction with the oxides of nitrogen. Where gases containing about 10% of oxides of nitrogen are utilised, the amount of oxygen should be approximately three to four times the theoretical quantity, and time should be allowed for the reaction to take place before admixture with the ammonia. If the gases after any stage of the process still contain oxides of nitrogen, a further quantity of oxygen, ammonia, and water may be added to produce more ammonium nitrate. By this process less ammonium nitrate is lost than by other methods of manufacture.—W. J. W.

Tungstates; Method of obtaining pure —. J. B. Ekeley and W. B. Stoddard, Boulder, Colo., U.S.A. Eng. Pat. 138,211, 20.3.19. (Appl. 6999/19.)

TUNGSTATE solutions prepared as described in Eng. Pat. 122,051 (U.S. Pat. 1,255,144; this J., 1918, 206 A) are purified by the process described in Eng. Pat. 122,264 (this J., 1919, 134 A), but both the oxidising agent (sodium hypochlorite) and the ammonia are added subsequently to the addition of the alkaline-earth salt.—S. S. A.

Alkali chromates and iodine; Manufacture of —. R. L. Datta, Calcutta, India. Eng. Pat. 138,291, 23.9.19. (Appl. 23,375/19.)

ALKALI iodide in admixture with an excess of sesquioxide of chromium or of chrome iron ore is heated to redness in a current of air and steam.

The whole of the iodine volatilises and is collected in a condenser. The residue is lixiviated with water to recover alkali chromate.—S. S. A.

Barium chloride and other chlorides of the alkaline-earth metals; Preparation of —. F. B. Shroff, Gwalior, India. Eng. Pat. 138,486, 1.4.19. (Appl. 8152/19.)

For the production of barium chloride free from barium sulphate or barium hydroxide, barytes is mixed with coal or other carbonaceous material and a quantity of magnesium chloride mother liquor, and introduced into a retort from one end and heated to about 600° C., steam being injected near the exit end to complete the reaction. The gases evolved are collected in a gas holder and the sulphur is recovered by burning the hydrogen sulphide in a Claus kiln. By lixiviation of the retort charge, barium chloride is dissolved, leaving a residue of magnesium oxide. The magnesium oxide may be dissolved out with sulphuric acid and recovered as magnesium sulphate, or the barium may be precipitated as sulphate by sulphuric acid, forming hydrochloric acid, which may be used to dissolve the magnesium oxide, thus producing magnesium chloride for subsequent operations. The process is applicable to the production of the chlorides of other alkaline-earth metals.—S. S. A.

Ferric sulphate; Basic — and method of preparing same. J. MacKaye, Cambridge, Mass., Assignor to River Smelting and Refining Co., St. Louis, Mo. U.S. Pat. 1,316,909, 23.9.19. Appl., 13.9.18.

A basic ferric sulphate, soluble in dilute sulphuric acid, is prepared by heating granular ferrous sulphate in contact with air at 200°–300° C., e.g., in a rotary cylinder provided inside with radial fins.

Alkaline icaters [brines]; Process of treating —. N. T. Bacon, Peace Dale, R.I., Assignor to The Solvay Process Co., Solvay, N.Y. U.S. Pat. 1,330,573, 10.2.20. Appl., 20.6.19.

IN a process of precipitating sodium carbonates from alkaline brine, the latter is treated first with flue-gas to effect a partial conversion of the lower carbonates into bicarbonate, and then with pure carbon dioxide to complete the conversion.

—W. E. F. P.

Manganese dioxide; Process of making conducting hydrated black —. C. Ellis and A. A. Wells, Montclair, N.J., Assignors to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,330,738, 10.2.20. Appl., 26.9.16.

By the oxidising action of a reactive hypochlorite compound on a slightly acid solution of a manganese salt in a mineral acid at about 100° C., a product suitable for use as a depolarising agent is obtained.—S. S. A.

Ferrous perchlorate; Preparation of pure, stable, technical —. E. Merck, Darmstadt. Ger. Pat. 309,133, 11.6.18.

AN impure solution of ferrous perchlorate is purified by digesting it with ferrous or ferric oxide, hydroxide, or carbonate, or with finely-divided metallic iron, whereby a brown gelatinous precipitate is produced which carries down with it the impurities present. The purified solution and the crystals obtained from it are much less readily oxidised, and also show a greater stability towards moisture than the original material.—A. R. P.

Perorides; Process for the production of stable solid —. W. Trumpp, Mannheim. Ger. Pat. 310,193, 16.3.18.

A PEROXIDE is mixed with a salt, the acid radicle

of which forms a soluble compound with the base of the peroxide; for example, equivalent parts of sodium peroxide and magnesium sulphate are digested with a very small quantity of water until interaction is complete, and the resulting mixture is dried.—A. R. P.

Lime; Process and apparatus for slaking —. J. Joachim and J. Schulte, Berlin. Ger. Pat. 315,241, 2.8.18.

WATER to be used for slaking lime is previously converted into steam by passing it through pipes embedded in the lime being slaked. The process is carried out in a drum around the inner wall of which a tubular worm is fixed; one end of the latter is connected to the water supply and the other end terminates in a steam pipe. The heat of combination of the lime and water is sufficient to transform more than the necessary water into steam.

—A. R. P.

Nitrogen, hydrogen, and carbon dioxide; Process for the preparation of technically pure — from natural gas and air. E. Herman, Buda-Pesth. Ger. Pat. 303,881, 12.4.11.

METHANE (natural gas) is burnt with the calculated quantity of air to give nitrogen and carbon dioxide, while the heat evolved is utilised to split up another portion of the gas into carbon and hydrogen. Both the combustion and decomposition of the methane are carried out under pressure as well as the separation of the carbon dioxide and water from the other products. At 950° C. methane is completely decomposed into carbon and hydrogen; at lower temperatures only partly so.—A. R. P.

Chromate and bichromate of sodium and potassium; Process for the conversion of — to chromic oxide and sulphate. F. M. Mooney, Montreal. U.S. Pat. 1,330,131, 10.2.20. Appl., 21.4.19.

SEE Eng. Pat. 129,958 of 1919; this J., 1919, 681 A.

VIII.—GLASS; CERAMICS.

PATENTS.

Glass furnace. Naaml. Vennoots. Glasfabriek "Leerdam" voorheen Jeekel, Mijnsen, and Co., Leerdam, Holland. Ger. Pat. 314,605, 6.12.18. Int. Conv., 11.1.18.

THE furnace is of the tank type fired with liquid

fuel. The jet of liquid fuel is driven into the furnace at the working end and under pressure so regulated that the highest temperature is developed at a distance from the burner at the melting end of the furnace where the fresh batch is fed in. In this way the jet of fuel on entering the furnace passes over the molten glass and not over the cold raw batch which might otherwise take up carbonaceous matter and yield discoloured glass.—H. J. H.

Quartz glass; Method of building up objects of — W. S. Quimby and F. W. Robinson, Assignors to Hanovia Chemical and Manufacturing Co., Newark, N.J. U.S. Pat. 1,330,611, 10.2.20. Appl., 23.11.18.

ARTICLES made of quartz glass are produced by heating a nucleus of quartz glass until it is plastic, applying a coating of powdered quartz, and reheating until the latter is fused, whilst at the same time elongating the article so as to keep its diameter constant. (See also Eng. Pat. 131,233 of 1919; this J., 1919, 769 A.)—A. B. S.

Plastic [ceramic] composition. E. J. Buckley, Longton, Staffs. Eng. Pat. 138,477, 24.3.19. (Appl. 7319/19.)

A PERMANENTLY plastic material which can, if required, be made hard by firing, is made by mixing any suitable pottery body with petroleum jelly or similar hydrocarbons. The mixture may be coloured with underglaze colours or metallic oxides.—A. B. S.

Refractory compounds; Process for producing — W. M. Handy, Spokane, Wash. U.S. Pat. 1,330,263, 10.2.20. Appl., 3.6.18.

A BASIC refractory material is made by calcining a pulverised mixture of calcined magnesite, an iron compound, and silica so as to cause the oxides of magnesium and iron to unite.—A. B. S.

Dryer for ceramic ware. A. Bühner, Constance. Ger. Pat. 312,765, 10.9.15. Addition to 311,258.

FOR use with certain classes of goods, for which moist air is preferable to hot dry air, the apparatus described in the chief patent (this J., 1919, 636 A) is modified by providing direct communication, which can be controlled by a damper, between the moist air flue and the fan chamber.—J. W. D.

IX.—BUILDING MATERIALS.

PATENTS.

Cement; Waterproof — S. Cabot, Canton. Assignor to S. Cabot, Inc., Boston, Mass. U.S. Pat. 1,305,645, 3.6.19. Appl., 26.2.16.

A COMPOSITION for use in the production of waterproof cement consists of powdered pitch (from coal tar, blast-furnace tar, coke-oven tar, or petroleum) brought into paste form in water by means of a protective colloid such as dextrin, soap, or the like. The composition may be mixed with slaked lime, clay, etc., before incorporation with the cement.

Slaking lime. Ger. Pat. 315,241. See VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron in iron ores; Determination of — by permanganate. L. Brandt. Chem.-Zeit., 1920, 44, 101—103, 121—122.

A METHOD described by Schwarz and Rolfe (this J., 1919, 179 A) is further criticised (see this J., 1919,

662 A); the author maintains that the addition of colloidal silica does not hinder the oxidation of the hydrochloric acid.—W. P. S.

Blast-furnace; Gas-fired — A. Torkar. Mitteil. Inst. Kohlenvergasung, 1919, 1, 81—85. Chem. Zentr., 1920, 91, 11., 36—37.

LIGNITE cannot be used directly in a blast furnace in place of coke; the gas obtained from it is, however, of high calorific value, and may be used both as a reducing and heating agent in the furnace. A shorter, broader furnace is most suitable for this work; the hot gases are passed downwards through the column of ore, thereby reducing it with consumption of one-fifth of the gas. Another fifth of the original gas mixture is burnt by the highly heated air-blast at the tuyères, and the remainder passes out of the furnace unburnt, and may be used for the production of power. Comparison with the coke-fired blast furnace and with electric smelting shows this process to be most economical.—A. R. P.

Spiegeleisen in steel manufacture; Use of — H. D. Hibbard. Report to U.S. Bureau of Mines, Jan. 7, 1918. Chem. and Met. Eng., 1920, 22, 209—210.

FOR convenience iron-manganese alloys containing 40% Mn or less are called spiegeleisen, alloys richer in manganese being termed ferro-manganese. For low-carbon steel the high ratio of manganese to carbon (about 12 to 1) in ferro-manganese is an important advantage. Spiegeleisen containing 31.25% Mn has been used on a commercial scale in basic open-hearth and Bessemer practice, but although the product is fairly free from red-shortness the ingot is too "thin skinned," so that seams, pits, and scabs are sometimes produced during reheating and rolling. The manganese content of the finished steel is 50—70% of that added. At another works the alloy is added in a molten condition, and for steels containing more than 0.3% C the use of spiegeleisen is considered to be the most effective method of adding manganese. The successful use of spiegeleisen is not yet proved in the manufacture of steel containing less than 0.1% C, low-carbon steels requiring a fine surface, ingots for plates or better quality sheets or castings made by the converter process where plants are not provided with means for melting re-carburising agents.—C. A. K.

Tin-plate; Use of hydrogenated oils in the manufacture of — W. D. Collins and W. F. Clarke. J. Ind. Eng. Chem., 1920, 12, 149—152.

OF various suggested substitutes for palm oil (see U.S. Pat. 1,242,532 of 1917) for covering the coating bath in the manufacture of tin-plate, hydrogenated cottonseed oil gave the most satisfactory results. Experiments on the effect of heat on various oils indicated that a satisfactory hydrogenated fish oil might be obtained. Laboratory tests showed that hardened cottonseed oil might be used without the evolution of unpleasant odours or excessive loss from volatilisation or from polymerisation. A commercial test during twelve weeks showed somewhat better results with hardened cottonseed oil than with palm oil; less oil was used, but no saving of tin was effected.—S. S. A.

Iron; Lead-coated — C. Baskerville. J. Ind. Eng. Chem., 1920, 12, 152—154.

To eliminate rupture or scaling of the protective lead coating applied to iron work, antimony may be used as a binding agent. The iron is pickled in sulphuric acid (6:1), washed with water, thoroughly blackened with an antimony chloride solution, again washed with water, and while still wet dipped through zinc chloride flux into molten lead-antimony alloy (12.5% Sb), then into molten lead, and finally quenched in oil. The process gave satisfactory results in the case of "shingles," iron wire

and netting, but was impracticable in the case of barbed wire, iron pipes, and shell cases on account of the irregularity of their surfaces. By the introduction of a preliminary pickling in hydrofluoric acid the process may be applied to cast-iron for filter presses and filter frames, an alloy coating being produced on to which a thick lead or other metal coating may be cast. Processes have been devised for plating lead-coated iron with copper or nickel or both.—S. S. A.

Brasses; Heat treatment of beta —. H. M. Brayton. Chem. and Met. Eng., 1920, 22, 211–217.

A COMMERCIAL brass containing 56.17% Cu, 41.24% Zn, 2.53% Pb, and 0.06% Sn showed a progressive fall in strength as the time of heating at 800° C. was prolonged. This is due first to the elimination of the effects of cold work on the original material, followed by a reduction due to the rapid grain growth at high temperatures. Heating at 600° C. for two hours, and quenching, gives the maximum strength combined with high ductility. Slow cooling from temperatures higher than 500° C. without mechanical work on the metal reduces the tensile strength, and large alpha crystals separate from the beta alloy. This treatment will produce an alloy possessing excellent shock-resisting properties if strength is not of vital importance. Similar experiments on an alloy containing 60.5% Cu, 38.67% Zn, and 0.75% Sn showed that the reduction in area falls off when the alloy is quenched from a temperature above 600° C., but that this property is not diminished appreciably if the metal is cooled slowly from temperatures up to 800° C.—C. A. K.

Alloys of copper, zinc, and nickel. L. Guillet. Comptes rend., 1920, 170, 460–462.

BRASSES, containing nickel, in which the copper content falls to 40% and even less and in which the nickel content rises to 15% are of particular interest because of their mechanical properties. Their breaking strain varies from 45 to 75 kilos. per sq. mm., with elongations of 45–18%. They are readily malleable at high temperatures, and in colour and resistance to oxidation they resemble German silver.—W. G.

Copper, silver, and gold; Growth phenomena of —. A. Beutell. Centr. Min., 1919, 14–28.

WHEN silver foil and silver sulphide or selenide or telluride were heated together *in vacuo* in a sealed tube at temperatures between 450° and 600° C. for several days remarkable growths of "hair" or "moss" silver were observed in the cooler end of the tube, the silver appearing to wander through the sulphide, from which the growths appeared to come. To obtain the growths it was necessary for the metal and the sulphide to be actually in contact. When silver sulphide was heated alone under similar conditions a small quantity of "hair" silver was formed, due to the partial decomposition of the sulphide. Much more rapid growths of hair silver were obtained when the tubes in which the heating was carried out had access to the air. Silver is not attacked by sulphur vapour *in vacuo* at 450° C. Copper gave similar growths, but much more slowly. In the case of gold the best results were obtained by heating gold telluride containing silver with silver foil for seven days at 500° C., when growths of "moss" gold containing silver appeared at the cooler end of the tube.—E. H. R.

Lead; Attempt to determine if common — could be separated into isotopes by centrifuging in the liquid state. J. Joly and J. H. J. Poole. Phil. Mag., 1920, 39, 372–375.

CENTRIFUGING liquid lead gives no evidence that a separation of isotopes has been effected.—J. F. S.

Alloys; Effect of centrifuging certain — in the liquid state. J. Joly and J. H. J. Poole. Phil. Mag., 1920, 39, 376.

CENTRIFUGING molten silver-lead alloys at a rate of 9000 revolutions per minute effects no separation, but similar treatment of lead-tin alloys brings about a certain amount of separation. Thus, an alloy containing 82 Pb and 18 Sn gives a top layer which is 1.8 lighter than the bottom layer.

—J. F. S.

Metals; Variation of thermal conductivity during the fusion of —. S. Konno. Sci. Rep. Tôhoku Imp. Univ., 1919, 8, 169–179.

THE thermal conductivity of tin, lead, zinc, and aluminium decreases with rise of temperature from ordinary temperatures up to the melting point. On fusion it drops considerably and on further increase of temperature it decreases slightly. The thermal conductivity of bismuth decreases to a minimum (at 160° C.) and then rises until the melting point is reached, where it increases considerably and then decreases slightly with further rise in temperature. In the case of antimony the conductivity falls to a minimum (at 182° C.), then rises to the melting point, where it decreases slightly and continues to decrease with further rise of temperature.—J. F. S.

New cyanide. Landis. See VII.

PATENTS.

Steel and other metals of high melting point; Reverberatory furnace for smelting —. J. Schmid, Lucerne, Switzerland. Ger. Pat. 313,919, 19.4.18.

ONE side of a chamber for melting steel or other metals is provided with three inlets so arranged that continuations of the same would meet in the centre of the chamber. Through the lowest opening flame from the white-heat zone of a gas producer passes into the chamber; the middle opening conveys combustible gas into the chamber; and the top opening admits the air necessary for combustion. Two gas producers, separated by a perforated wall, are attached to the chamber, and the gas generated in the producer filled with fresh coal is heated by means of the other producer in which flame formation takes place.—L. A. C.

Ores; Process and apparatus for treating — in the blast furnace. L. P. Basset, Paris. Eng. Pat. 112,275, 21.12.17. (Appl. 18,974/17.) Int. Conv., 22.12.16. Addition to Eng. Pat. 109,452, 7.9.16 (this J., 1918, 771 A).

READILY burning carbon in a very finely divided state, preferably in the form of "flour," is delivered from a hopper by an endless screw, into one of the tuyères of a blast furnace in the correct amount to bring about reduction of the ore, and from a second hopper powdered anthracite is similarly supplied in amount sufficient to effect the desired carburisation of the reduced iron. (Reference is directed to Eng. Pat. 109,452; *loc. cit.*)—T. St.

Alloy, and method of making and using same. A. G. Mumford, Ltd., and A. G. Mumford, Colchester. Eng. Pat. 138,228, 14.1.19. (Appl. 9160/19.)

A WHITE-METAL alloy consisting of Sn 61, Cu 29.7, and Zn 9.3, is alloyed with copper in the proportion Cu 80.36, white-metal alloy 19.64%. The resulting alloy is cast in iron chills to produce floats for automatic feed water regulators and the like, which are subjected to very high and varying temperatures and pressures.—T. St.

Electrodes of electric [smelting] furnaces; Manufacture of —. O. R. Olsen, Christiania, Norway. Eng. Pat. 138,272, 6.8.19. (Appl. 19,383/19.)

ELECTRODES for use in smelting copper, iron, and

other ores are prepared by adding to the usual constituents about 25% of the concentrate of the ore under treatment.—W. E. F. P.

Furnace; Mechanical — for roasting ores. Huntington, Heberlein, and Co., Ltd., and H. C. Bingham, London. Eng. Pat. 138,443, 22.2.19. (Appl. 4474/19.)

IN an ore-roasting furnace of the type having superposed hearths on which operate rabbles carried by a central shaft, the space beneath the muffle hearth is divided into two annular concentric flues, and the heating gases from the firing chamber are made to pass first through the inner flue and then, in the opposite direction, through the outer flue. The temperature thus produced on the muffle hearth is sufficient to ensure the decomposition of sulphates before the roasted ore is discharged from the furnace. By dividing the flues, by means of tiles, into upper and lower passages, the lower concentric flues thus formed serve for the supply of preheated air, which may be used either in the combustion chamber or in the muffle as desired.—T. St.

Roasting furnaces for sulphurous ores. Soc. Anon. de Vedrin, and J. Marcotty, Vedrin, Belgium. Eng. Pat. 138,472, 18.3.19. (Appl. 6739/19.)

AN apparatus for the continuous and intensive roasting of sulphurous ores, particularly blende, comprises an inclined, cylindrical, rotary furnace, the upper part of which is divided into several radial compartments which are subdivided lengthwise into sections which are offset or placed in alternation with one another, the lower part being provided with vanes which raise the material and drop it through the current of gas. The ore is thus subjected to a creeping motion and to successive overturnings in the upper part of the furnace and then spread through the current of oxidising gases in the lower part, whereby a maximum oxidation with a reduced amount of dust is obtained.—S. S. A.

Reverberatory furnace, for melting metals and alloys of all kinds. F. Wüst, Aix-la-Chapelle. Ger. Pat. 315,264, 4.1.17.

THE furnace is provided with a shaft situated at the opposite end to that at which the fuel and air are admitted. The metal is charged into the shaft and the hot flue gases leaving the furnace play around and through the lower part of the column of the charge, thereby melting it. The shaft is so constructed that the burning gases are concentrated into a pointed flame.—A. R. P.

Sherardising apparatus. C. J. Kirk, New Castle, Pa. U.S. Pat. 1,327,102, 6.1.20. Appl., 1.3.19.

THE apparatus comprises a rotary retort with external and internal electric heating units.—B. N.

Ores; Separation of —. A. A. Lockwood, Merton Park. U.S. Pat. 1,329,127, 27.1.20. Appl., 24.11.17.

A LAYER of pulp containing the material to be separated is caused to flow over a supporting surface; the pulp is agitated and baffled during its passage over the surface, and electric currents are passed through the pulp between baffling elements, thereby evolving gas which adheres to and buoys up certain of the components of the pulp.—J. F. B.

Gold; Production of white —. D. Belais, New York. U.S. Pat. 1,330,231, 10.2.20. Appl., 5.10.18.

A WHITE gold alloy is composed of a major part of gold and lesser proportions of nickel and zinc.—T. St.

Zinc-retort residues; Process for working up —. K. Eichhorn, Hildesheim. Ger. Pat. 309,162, 29.3.18.

THE residues are smelted in the producers which supply the gaseous fuel for the distillation furnace. The gases are freed from zinc oxide and then used for heating the retorts. The heat generated in the producers is more than sufficient to melt the metals as well as the gangue, which are tapped off as usual.—A. R. P.

Copper alloys containing valuable metals; Process for treatment of —. Hirsch Kupfer- und Messingwerke A.-G., Halberstadt. Ger. Pat. 312,394, 13.3.18. Addition to 301,265 (this J., 1920, 161A).

TO obtain the copper sulphate which must necessarily be added to maintain the concentration of the bath during the electrolysis of blister copper, the slag from the furnace in which the copper has been melted is treated with a portion of the electrolyte drawn from the bath. Copper present in the slag, as metal, or as cuprous and cupric oxides, silicates, and ferrites, is rapidly extracted, especially if the slag is first crushed and calcined. The silica then separates out more rapidly, and the copper, being oxidised to cupric compounds, is more rapidly extracted.—H. J. H.

Ductile metal in wire or tube form; Production of —. L. Weiss, Barmen. Ger. Pat. 314,791, 7.1.14.

THE metal is precipitated upon a core of the same or another metal which under the conditions is inert, by heating a volatile salt of the metal, which either dissociates at a high temperature or is reduced by an admixed gas, e.g., hydrogen. The resulting rod can be either wire drawn or rolled out. Two or more metals, either together or separately in layers, can be deposited by suitably choosing the materials and conditions, so that alloys which are otherwise unobtainable can be prepared. Volatile chlorides or metallo-organic compounds, such as the metal alkyls and the acetoacetates, are suitable materials. Thus a wire of platinum or tungsten heated electrically in a mixture of tungsten hexachloride and hydrogen can be coated with a bright, dense, adherent layer of tungsten, the thickness of which depends on the temperature and time of the heating.—H. J. H.

Annealing and melting metals and alloys without oxidation; Process for —. A. Barth, Frankfurt. Ger. Pat. 314,990, 22.5.18.

THE metal is heated after applying a layer of suitable protective material, e.g., phosphoric acid or fusible phosphates. The process may be applied to the fusion of turnings, to casting, and enamelling processes.—H. J. H.

Aluminium alloys containing copper, tin, antimony, and magnesium; Production of —. A. Manhart, Vienna. Ger. Pat. 314,999, 23.5.18. Int. Conv., 10.4.14.

IN aluminium alloys a portion of the copper—say one-third—can with advantage be replaced by manganese-copper alloy. The resulting alloys are hard without being brittle.—H. J. H.

Alloy suitable for protective coatings for iron and steel. Akt.-Ges. der Dillingen Hüttenwerke, Dillingen. Ger. Pat. 315,074, 20.10.18.

THE alloy contains 0.5 part of aluminium, 1 part of antimony, 1 part of tin, and 97.5 parts of soft lead. Instead of antimony, an antimonial lead with 8–10% Sb may be used. The aluminium is first warmed, and the fused hard lead added, then the tin, and lastly the soft lead.—H. J. H.

Metal matrix; Preparation of a — to obtain easily detachable electro-deposits. M. Schlöter, Berlin-Wilmersdorf. Ger. Pat. 315,711, 1.12.17.

THE matrix is treated with an aqueous solution of gelatin, glue, or similar material which, by treatment with reagents or light, is rendered insoluble. The coating should be so thin that it offers no noticeable resistance to the current; it withstands a bath temperature of more than 50° C.—A. R. P.

Blast-furnace slags; Treatment of — [for production of sulphur dioxide]. H. Petersen, Berlin-Steglitz. Ger. Pat. 309,134, 26.5.18.

THE slag is tapped from the blast-furnace into an insulated ladle, from which portions are removed to smaller vessels in which they are treated with a current of air to convert the contained sulphur into sulphur dioxide, which is used for making sulphuric acid. Two or more vessels may be used simultaneously for the operation in such a manner that the first half of the treatment in the second vessel corresponds with the second half of the treatment in the first vessel, and *vice-versa*. In this way a regular supply of sulphur dioxide is obtained.

—A. R. P.

Furnaces for heating [metal] blooms [; Slide tracks for —]. M. Mathy, Flemalle-Grande, Belgium. Eng. Pat. 138,712, 21.2.19. (Appl. 4413/19.)

XI.—ELECTRO-CHEMISTRY.

Electrode; Simple hydrogen —. C. H. Bailey. J. Amer. Chem. Soc., 1920, 42, 45—48.

A SIMPLE hydrogen electrode may be constructed as follows:—A piece of 7 mm. bore tube is blown out at one end to form a bulb of 15 mm. diam.; the tube is then bent to form an angle of about 45° at a distance of 50 mm. from the top of the bulb. The other limb of the tube is about 80 mm. long and is fitted with a ground glass stopper. The metal electrode is a thin platinised gold disc of 5 mm. diam. welded to a piece of thin platinum wire and fused into the shorter limb of the tube about 5 mm. above the bend. The tube is filled with the liquid under investigation and then by means of a fine tube the bulb is filled with hydrogen, thus expelling some of the liquid. The tube is stoppered, care being taken to exclude air, and vigorously shaken until the solution is saturated with hydrogen. Connection is made with the standard electrode by means of a siphon tube filled with saturated potassium chloride solution and inserted well down the longer limb. The electrode is rapid in action and gives reliable results.—J. F. S.

PATENTS.

Electrolytic cell [for oxidising mercury]. H. W. Matheson, Shawinigan Falls, Canada. Eng. Pat. 138,406, 23.1.19. (Appl. 1731/19.)

AN electrolytic cell for oxidising mercury consists of a shallow, insulated metal pan or anode, covered by a hood, and containing a layer of mercury above which a metal cathode is suspended. The pan is provided with annular ribs by which the mercury is prevented from coming in contact with the sides of the pan, so that electrolysis occurs only between the mercury and the cathode, the pan serving as a conductor. Means are provided for supplying mercury and the electrolyte to the pan and for gauging the amount of each; and a stirring device having a variable speed drive located above the hood is disposed just above the level of the mercury. The metal cathode is provided with openings through which the gases produced pass into the hood, whence the lighter and heavier constituents escape by upper and lower outlets.—W. E. F. P.

Electrolytic cells [for oxidising mercury]. H. W. Matheson and F. T. Kaelin, Shawinigan Falls, Canada. Eng. Pat. 137,609, 23.1.19. (Appl. 1732/19.)

THE cell consists of a metal receptacle lined with concrete or the like and provided with an anode buried in the lining, and a cathode supported by the lining out of contact with the anode. The cathode is disposed horizontally, and comprises a hub, with radial supports projecting therefrom, and inclined plates secured between the supports in spaced overlapping relation. Means are provided for raising and lowering the cathode. The receptacle is provided with an aperture in the bottom through which the lining and anode project, and an electric conductor is clamped on to the anode out of contact with the shell. A stirring device is provided between the anode and cathode, with means for rotating it at different speeds. The stirring device may pass through the cathode, and a centre pin on the anode engages the stirrer and holds it out of contact with the cathode.

—B. N.

Electrolytic apparatus [for production of oxygen and hydrogen]. E. O. Benjamin, Newark, N.J., U.S.A. Eng. Pat. 137,553, 1.8.18. (Appl. 12,567/18.) Int. Conv., 1.8.17.

A THIN cast-iron frame constitutes the top, bottom, and sides of the cell, and two plates of conducting material applied to two opposite faces of the frame constitute the end walls, which are connected to a source of current to form the working electrodes. The frame is insulated from the walls, and the cell is divided into compartments by a porous diaphragm. Passages for separately collecting and leading off oxygen and hydrogen from the separate compartments, and passages for supplying electrolyte to each compartment, are formed in or upon the insulated frame, and may be moulded therein. The frame is provided at the top with a cavity or cavities into which the electrolyte extends, so that the level thereof is maintained above the uppermost portion of the diaphragm, and above the uppermost portion of the inner surfaces of the walls constituting the electrodes. Water-sealed exits are provided for the gases collected within the chambers, and a gas vent is connected with the exits below the level of the electrolyte in the water-seals.—B. N.

[Electric] battery. R. J. Crowley, Assignor to A. Kramer, T. R. and H. B. Tennant, and M. Rothman, Dallas, Tex. U.S. Pat. 1,306,214, 10.6.19. Appl., 1.5.17.

A PASTE composed of a salt of aluminium, *e.g.*, the sulphate, an oxide of lead, *e.g.*, litharge, and sulphuric acid, is used as the active material on the positive and negative plates of storage batteries. The paste is applied to grids of lead or aluminium or an aluminium alloy, and the plates are then "formed" by the action of an electric current, using sulphuric acid of sp. gr. 1.2 as electrolyte.

Electrolytic cell. A. M. Griffin, Kansas City, Mo. U.S. Pat. 1,327,091, 6.1.20. Appl., 21.8.18.

THE cell comprises a pair of flanged "pan-members," secured together in gas- and water-tight relation, and insulated from each other. A diaphragm permeable to water and electricity divides the cell into two compartments. A plate is arranged within each compartment, and is secured to the adjacent side wall of the cell, each plate being corrugated and in contact at the crests of the corrugations with the adjacent wall of the pan. Openings are provided between the corrugations, with walls projecting inwards flanking the openings.—B. N.

Electrolytic apparatus. E. O. Benjamin, Newark, N.J. U.S. Pat. 1,328,981, 27.1.20. Appl., 24.6.18.

AN electrode for electrolytic apparatus comprises a plate of conducting material having its surface formed or provided with triangular pyramid frustums vertically alined, so as to form upward channels between them and oblique channels between the upward channels.—B. N.

Electrolytic apparatus. V. M. Weaver, Harrisburg, Pa., Assignor to Weaver Co. U.S. Pat. 1,329,315, 27.1.20. Appl., 9.7.15.

AN apparatus, for treating a chloride, comprises a closed chamber adapted to contain an electrolyte, with a conducting interior bottom as one electrode and a conducting block depending from a sealed cover as the opposite electrode. Means are provided for mechanically feeding non-gaseous material into the electrolyte at a definite and controlled rate.

—B. N.

[Aluminium] plates for electrolytic cells; Preparation of —. J. Coulson, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,330,581, 10.2.20. Appl., 7.10.15.

ALUMINIUM for use in electrolytic cells is immersed in hydrofluoric, hydrochloric, and nitric acids in succession, then cleansed, heated for several hours at a temperature not exceeding 600° C., and cooled.

—W. E. F. P.

Electric furnace; Three phase —. F. T. Snyder, Oak Park, Ill., Assignor to Industrial Electric Furnace Co., Chicago, Ill. U.S. Pat. 1,327,174, 6.1.20. Appl., 11.3.18.

AN electric furnace, having two upper electrodes and a bottom contact, is combined with three transformers, the secondaries of which are so connected as to produce a phase angle, between the voltages existing between the bottom contact and the upper electrodes, greater than 60° and less than 90°.

—B. N.

Electric precipitator. H. I. Frisbie, Anaconda, Mont. U.S. Pat. 1,329,237, 27.1.20. Appl., 6.1.19.

A PRECIPITATING chamber is provided with an inlet and outlet and with electrodes, suitably disposed across the chamber, forming collectively zones or fields of opposite polarity. The electrodes forming the zones of one polarity extend substantially the width of the precipitating chamber, whilst the electrodes forming the zones of opposite polarity are spaced a suitable distance from the walls of the chamber, and from the first-mentioned electrodes to prevent short-circuiting therewith, whereby a circuitous course is ensured for the gases with maximum precipitation.—B. N.

Electric insulating moulded articles; Process of manufacturing —. F. Grünwald, Pozsony, Hungary. U.S. Pat. 1,330,444, 10.2.20. Appl., 3.7.17.

A MIXTURE of inert substances, phenol-formaldehyde condensation products, and a liquid in which the condensation products are insoluble and which has a boiling point and vapour tension near to those of water, is moulded, and the moulded articles are hardened by rapid heating under atmospheric pressure.—W. E. F. P.

Manganese dioxide cells; Process for regeneration of depolarisation masses from exhausted —. G. Klopstsch, Berlin. Ger. Pat. 315,335, 8.7.17.

THE material is powdered and the salts contained therein are extracted by boiling with a suitable solvent, e.g., ammonium chloride. The washed

residue is re-oxidised by heating it under pressure with strong oxidising agents, such as hypochlorous acid or its salts or chloric acid. Oxidation may also be effected by electrolysis in the presence of any of the above compounds or of substances which, by electrolysis, give rise to hypochlorites (e.g., magnesium chloride) or to strongly oxidising compounds (e.g., bichromate, permanganate).—A. R. P.

Suspended material from gases. U.S. Pats. 1,329,737 and 1,329,817—8. See I.

Hydrogenated oils in manufacture of tin-plate. Collins and Clarke. See X.

PATENTS.

Oils and other liquids; Process and apparatus for deodorising, purifying, distilling, and vaporising —. J. T. Bateman, London. Eng. Pat. 138,388, 14.11.18. (Appl. 18,691/18.)

OIL, after passage through a preheater of the type described in Eng. Pat. 24,605 of 1914 (this J., 1915, 367), is led through a coil submerged in a heated metal bath, and then into an enclosed or sealed chamber in which it is brought in contact with superheated steam. The steam is led into the chamber by means of perforated tubes arranged on the bottom of the chamber, and the chamber may be divided into compartments by partitions, the oil flowing over and under alternate partitions, or the oil may be led through two or more separate chambers. The vapours from the chamber are led to the preliminary heating system, and the oil, after treatment, is conveyed away through cooling coils.—L. A. C.

Lanoline; Separation of — from crude wool-grease and the like. F. J. Metzger, New York. U.S. Pat. 1,330,210, 10.2.20. Appl., 7.6.16. Renewed 16.6.19.

CRUDE wool-grease is subjected to the action of a

solution of an alkali and an alkali salt, the alkali being present in sufficient quantity to saponify all the free fatty acid present.—B. V. S.

Oil and soap solution and process of making same. J. A. De Cew, Montreal, Canada. U.S. Pat. 1,330,173, 10.2.20. Appl., 25.2.18.

A STABLE emulsion of oil with about 25% of its weight of soap is prepared by mixing the ingredients while hot, discharging the hot mixture into hot water under pressure, and then discharging the product into cold water.—L. A. C.

Emulsifying oil solutions and the like; Method and apparatus for —. J. A. De Cew, Montreal, Canada. U.S. Pat. 1,330,174, 10.2.20. Appl., 17.5.18.

OIL or the like and water are heated in separate reservoirs and forced by pressure through pipes into a common chamber. The oil and water inlets into the chamber consist of unequally perforated plates, whereby the liquids are atomised, and, as they mix, form an emulsion, which is led away through another perforated plate having as many perforations as both the inlet plates, into a reservoir containing cold water.—L. A. C.

Sulphonic acids. U.S. Pat. 1,330,624. See IIa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Coumarone resins and formolites. M. Ragg. *Farben-Zeit.*, 1919, 25, 16—18, 61—62, 105—106, 145—146. *Chem. Zentr.*, 1920, 91, II., 15.

COUMARONE resin should contain neither free nor combined sulphuric acid, as all sulphuric acid compounds rust iron. The resin is employed as varnish for lithographs, as well as in the manufacture of lacquers and paints; it also finds employment as a substitute for colophony in the manufacture of explosives. When used for sizing paper, it must be emulsified with animal glue or resin soap. The presence of added impurities is detected by the formation of a precipitate on the addition of sulphuric acid to the resin in benzol. Formolites (phenol-formaldehyde resins) may be divided into four classes: Insoluble in the usual solvents and infusible, *e.g.*, bakelites; soluble in certain solvents, but giving a lacquer which must be heated to be durable, *e.g.*, bakelite A and B, resinite; soluble in alcohol, and giving a usable varnish without heating, *e.g.*, issolin; soluble also in fatty oils and other solvents, *e.g.*, albertole. The necessary heating of the varnishes prepared from these condensation products somewhat limits their application; they can be employed as stove lacquers or for insulation, but their price prohibits their use on a larger scale. Issolin is recommended as a substitute for spirit-soluble hard resin, shellac, or Manila copal, and in alcoholic solution is employed for insulating armatures, electro-magnets, and coils.—L. A. C.

PATENTS.

Antimony colours [for rubber]. E. F. Morris, Roby. Eng. Pat. 138,137, 8.10.18. (Appl. 16,335/18.)

FOR the preparation of antimony colours which do not blacken during the normal vulcanisation process, solutions of antimony are treated first with alkali-waste liquor (and/or a similar solution

obtained by boiling a mixture of lime, sulphur, and water), to which a soluble thiosulphate may be added, and then with a suitable excess of sulphuric acid (or nitre-cake) or hydrochloric acid, whereby sulphur is precipitated with the antimony sulphide.—W. E. F. P.

Resinous condensation products of phenol and formaldehyde; Production of —. Chem. Fabr. K. Albert, and L. Berend, Amöneburg. Ger. Pat. 301,381, 15.10.13. Addition to 301,374.

FORMALDEHYDE or a substance which liberates it is treated with mixtures of *m*-cresol or its homologues with other phenols in presence or absence of condensing agents, but only for such time and in such proportions that practically only the meta-substituted phenols react with the formaldehyde. The other phenols are then removed by distillation. The process can be carried out with a cresol mixture which has been specially freed from *o*-cresol, *e.g.*, by fractional distillation, the quantity of formaldehyde taken corresponding with the proportion of *m*-cresol in the mixture. Further purification of the still fusible resin is effected by distillation *in vacuo*. Alternatively, the condensation may be effected with a proportion of formaldehyde adjusted to the quantity of *m*-cresol and the removal of *o*- and *p*-cresol effected subsequently, *e.g.*, by sulphonation of the *o*-compound and separation of the *p*-compound by known methods. To avoid too rapid condensation, which leads to the immediate production of infusible products, the mixtures condensed should not be too rich in *m*-cresol, and slightly less formaldehyde than that theoretically required can be taken. A suitable cresol mixture is one containing 50—60% of the *m*-compound.—H. J. H.

Drier. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 305,692, 2.9.17.

THE drier consists of metallic compounds of 1,3-diketones or 1,3-ketocarboxylic acids; for example, manganese acetoacetate, cobalt acetylpinacolin, lead acetoacetanilide, or similar metallic compounds of acetylacetone, oxaloacetic acid, oxaloacetic esters, di- or tri-benzoylmethane. The products can be used alone or mixed with each other or with other known driers.—A. R. P.

Resin or varnish; Process for making a —. Vereinigte Chem. Werke A.-G., K. Lüdecke, und L. Mamlock, Charlottenburg. Ger. Pat. 307,622, 30.9.17.

FURFURAL is treated with a mineral acid and a metal (preferably zinc, but not an alkali metal) that evolves hydrogen from acids. The product differs from furfuryl alcohol made by reduction of furfural with sodium amalgam and acetic acid; it is insoluble in water, but soluble in alcohol and chloroform, and can be used in the varnish industry mixed with other substances in a suitable solvent.—A. R. P.

Varnish; Preparation of a — from indene. M. Claasz, Munich. Ger. Pat. 310,783, 19.2.18.

INDENE is condensed with formaldehyde in the presence of mineral acids, whereby a colourless balsam is obtained which is liquid when warm and gummy when cold, and which dries on exposure to the air.—A. R. P.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber obtained by coagulation of latex; Resistance of —. V. Henri, Caoutchouc et Gutta-Percha, 1920, 17, 10196—10202.

By coagulating latex with sulphuric acid in the presence of phenol it is possible to obtain sheets of

raw rubber of surprising strength and elasticity, the breaking strength being 190 grms. per sq. mm. and the permanent set small. After heating for 20 minutes at 100° C. the extensibility and permanent set are greater but the breaking strength is unaffected; heating for 4 hours at 110° C., however, causes the rubber to become very weak and plastic. If strips of the rubber are vulcanised in a sulphur bath at 135°–140° C., a very elastic product is obtained with a breaking strength of 666 grms. per sq. mm.—D. F. T.

PATENTS.

Heat-resisting [rubber] packing. J. Stromeyer, Philadelphia, Pa. U.S. Pat. 1,330,148, 10.2.20. Appl., 15.3.17.

THE material consists of finely-divided magnesite incorporated in a vulcanised rubber compound.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins. III. Chlorogenic acid, the tannin-like constituent of coffee. K. Freudenberg. Ber., 1920, 53, 232–239.

ACCORDING to Gorter (see this J., 1908, 242, 464; 1910, 587; 1911, 235) chlorogenic acid is formed by the loss of a molecule of water from two molecules of hemichlorogenic acid. This view is not readily reconciled with its fission by penicillium and mucor varieties or, as in now shown, by tannase into caffeic and quinic acids. Further, chlorogenic acid, which Gorter considered to be anhydrous, contains 0.5 H₂O, thus accounting for the difference between it and the hypothetical hemichlorogenic acid. Chlorogenic acid is simply a depside of caffeic and quinic acids, the carboxy group of the former being united to one of the hydroxy groups of the latter as indicated by the formula,

$C_6H_3(OH)_2 \cdot CH : CH \cdot CO \cdot O \cdot C_6H_3(OH)_2 \cdot CO_2H$.
(See further J. Chem. Soc., Apr., 1920.)—H. W.

Casein in glue making; Influence of the method of manufacture on the use of —. S. Buttermann. J. Ind. Eng. Chem., 1920, 12, 141–144.

To obtain good results in the manufacture of water-resistant glue from casein (see this J., 1919, 732A), variations in the proportions of the ingredients are necessary in using caseins of different origin. Analyses of a large number of samples of casein manufactured in various ways showed that the ash content was the chief variant, and experiments were carried out to determine the effect of the ash content on the amount of water required to make casein glues of similar consistency. 100–200 grms. of dry, powdered casein was mixed with x parts of water, and after soaking for a few minutes a quantity of a suspension of lime (one part of hydrated lime to six of water) was stirred in to give 15% of lime on the weight of casein. A quantity of sodium silicate of sp. gr. 1.4, equal to 0.7 of the weight of casein, was then added and the mixture stirred vigorously. It was found that the ash content plotted against the ratio of the total water used to the casein gave a graph represented by an equation of the type, $y = mx + c$. It is thus possible to plot a graph for any casein glue formula from which the necessary variation in water content can be determined according to the ash content of the casein to be used. The author describes briefly various methods used in the manufacture of casein.—S. S. A.

Gelatin; Liquefaction of — by salts. T. R. Briggs and E. M. C. Hieber. J. Phys. Chem., 1920, 24, 74–75.

SOLUTIONS of 5% gelatin in 33% potassium chloride

solution set in 30 mins. at 19° C.; in similar solutions of magnesium chloride or ammonium chloride the solutions set in 24 hours, but in solutions of zinc chloride, potassium thiocyanate, potassium nitrate, or ammonium nitrate they do not set in 36 hours. The salt may be removed from the last group by dialysis and the gelatin then sets. The process of liquefaction and gelatinisation by salts is strictly reversible.—J. F. S.

Electrolytes; Penetration of — into gels. I. Penetration of sodium chloride into gels of agar-agar containing silver nitrate. W. Stiles. Biochem. J., 1920, 14, 58–72.

THE rate of penetration of sodium chloride into agar gels containing silver nitrate is proportional to the square root of the time; it is dependent on the initial concentration of the sodium chloride, and may be expressed by the formula $P/\sqrt{t} = k \log c + k'$, where P is the penetration, t the time, c the initial concentration of the sodium chloride, k a constant depending on the nature of the penetrating salt, and k' a constant depending on the concentration of the silver nitrate in the gel. (See also J. Chem. Soc., Apr., 1920.)—J. F. S.

Turbidimeter for gelatin. Sheppard. See XXIII.

Tanning material [from sulphite-cellulose waste liquors]. W. Mensing, Freiberg. Ger. Pat. 304,349, 15.2.16.

A TANNING bath consists of sulphite-cellulose waste liquor which has been heated with solid or liquid oxidising agents, such as chlorates, nitrates, permanganates, or chromates.—L. A. C.

Tanning animal skins; Process for —. Deutsche Koloniale Gerh- und Farbstoff-Ges.m.b.H., Karlsruhe. Ger. Pat. 305,516, 25.12.15.

ANIMAL hides are steeped several times alternately in separate baths of a 2–5% formaldehyde solution and a solution of an aromatic compound which is either soluble in water or forms soluble salts and forms a compound with formaldehyde insoluble in water, e.g., a 1–2% solution of α -naphthylamine hydrochloride, or a 2% solution of resorcinol. The resorcinol bath yields a pliable leather of good tensile strength.—L. A. C.

XVI.—SOILS; FERTILISERS.

Plants; Action of chlorine and different vapours on —. P. Guérin and C. Lormand. Comptes rend., 1920, 170, 401–403.

MOST plants maintained for one hour, sometimes two hours, in an atmosphere containing 1 part in 2000 of chlorine, palite (chloromethyl chloroformate), bromoacetone, chloropicrin, or mustard gas (yperite, dichlorethyl sulphide) resist the action of these gases. The plants lose their leaves, but new ones appear after a more or less prolonged interval, and in the end the plant resumes its normal vegetation. The leaves die by reason of plasmolysis, the phenomenon being most rapid with chlorine and very slow with mustard gas under the experimental conditions.—W. G.

Calcium; Absorption of — by the roots of plants and its antitoxic properties with respect to copper. L. Maquenne and E. Demoussy. Comptes rend., 1920, 170, 420–425.

THE antitoxic action of calcium with respect to copper is not due to its preventing the penetration of this latter metal, since, even when present in excess, calcium does not hinder the absorption of copper by the roots of plants, and its diffusion into their aerial organs. Similarly the presence of copper

does not prevent the assimilation of calcium, so that the poisonous effect of copper is not due to its depriving the young plant of one of its essential nutrients. The antitoxic action of calcium is rather physiological in favouring the growth of the plant, thus increasing the volume into which the copper diffuses and hence, within certain limits, preventing any dangerous accumulation of this latter metal.—W. G.

Calcium cyanamide; Improvement of crude — [for use as fertiliser]. J. Baumann. Chem.-Zeit., 1920, 44, 158–159.

CRUDE calcium cyanamide has a number of disadvantages as a nitrogenous fertiliser, and to obtain the nitrogen in a more suitable form the author suggests a combination of the cyanamide and ammonia-soda processes. It is proposed that the ammonia for the process should be obtained from calcium cyanamide, and that the liquors from the sodium bicarbonate, which contain, after boiling, 135 grms. of ammonium chloride and 124 grms. of sodium chloride per litre, should be evaporated to crystallise out ammonium chloride. The ammonia is thus recovered as chloride for use as a fertiliser, and the lime which would have been used for regeneration of the ammonia is used for the manufacture of cyanamide. Alternatively, the ammonia could be regenerated in the usual way with lime, and the calcium chloride-sodium chloride liquors then treated successively with ammonia from calcium cyanamide and with carbon dioxide, whereby calcium carbonate would be precipitated and ammonium chloride could be crystallised from the solution. It is calculated that by the adoption of the proposed combination of the two processes considerable economies would be effected. Ammonium chloride has the advantage that it can be used for mixed fertilisers. Mixed with superphosphate, it does not affect the solubility of the latter nor cause it to become lumpy. Ammonium bicarbonate, which is quite as good as ammonium sulphate as a fertiliser, could also be prepared simply and cheaply from calcium cyanamide, but it cannot be mixed with superphosphate.—E. H. R.

PATENTS.

Fertiliser. L. T. Buck, Weems, Va. U.S. Pat. 1,330,369, 10.2.20. Appl., 30.9.19.

Decolorising-carbons; Process for the regeneration of —. G. Blardone, New Orleans, La. U.S. Pat. 1,327,222, 6.1.20. Appl., 9.7.17.

DECOLORISING and deodorising carbon is revived by washing with sodium bisulphite.—J. F. B.

Adhesive paste; Preparation of an —. Veredelungsges. für Nahrungs- und Futtermittel m.b.H., Bremen. Ger. Pat. 315,536, 28.3.18.

STRAW is boiled with caustic soda, with or without

pressure, and the solution neutralised with a mineral or organic acid, especially formic or acetic acid, or with carbon dioxide in excess. The resulting precipitate is preserved in a half-dried state and is suitable for use as an adhesive with fabrics or paper. Salts that produce an insoluble base with the soda, such as aluminium sulphate or formate, calcium or magnesium chloride, may be used for neutralising, in which case the precipitated hydroxide remains mixed with the precipitated paste.—A. R. P.

XVIII.—FERMENTATION INDUSTRIES.

[Barley;] **Further experiments on titration in stages** [applied to —]. A. Reichard. Z. ges. Brauw., 1919, 42, 223–227. (See also this J., 1917, 399; 1918, 523 A.)

A SAMPLE of barley of pure strain (originally propagated from a single plant) was divided by screening into two fractions containing the small and large corns respectively, and the acidities of the two fractions were compared by titration in stages (*loc. cit.*), followed by formol titration (*cp. this J.*, 1920, 202 A). The titrations were carried out on extracts made directly from the ground material, and also on extracts made after destruction of the enzymes (*cp. this J.*, 1918, 523 A). All the acidity values found, referred to a given weight of dry substance, were higher for the small than for the large corns. The difference was most marked for the acidity representing substances acid to phenolphthalein but not to litmus. As these substances consist largely of amino-acids, and the latter are required by the barley embryo for synthetic processes during germination, the relatively large amounts of them present in small corns must tend to accelerate the early stages of germination. This would account for the rapid heating which has been observed in the case of small-corned barleys on the malting floors (*cp. Delbrück, this J.*, 1902, 556).—J. H. L.

Amolytic action of the diastase of *Aspergillus oryzae*; Method of testing the —. S. A. Waksman. J. Amer. Chem. Soc., 1920, 42, 293–299.

IN connection with the removal of size from textile goods, the following is a convenient method of measuring the starch-liquefying power of enzymes. A suitable amount of the enzyme solution is added to 10 c.c. of a 2% paste of raw potato starch which is maintained at 40° C., and the time required (from 1 to 15 mins., according to the quantity of enzyme) for the liquid to become clear is observed. The determination of the end-point may be facilitated by staining the starch, preferably with Neutral Red. When the stage of hydrolysis corresponding with this end-point is tested with iodine, it is found to be identical with that at which no intense blue colour is obtained, but only a deep-brown to faintly violet-brown colour or faint blue-violet colour, showing that all the starch paste has been transformed into dextrins. Comparing the starch-liquefying powers of malt enzymes and those obtained from *Aspergillus oryzae* (water extract known commercially as Polyzyme), the first are found to give a higher Lintner value, while the second give a higher liquefying value. The ratio of the latter to the former in the case of malt preparations is 1:4 to 1:5, while in the case of *Aspergillus oryzae* enzyme it is 1:1 to 1:5:1.—H. W.

Water; Analysis of brewing —. H. Lüers. Z. ges. Brauw., 1919, 42, 209–210, 219–221, 227–228, 210–211, 252–254, 263–265.

THE author gives working details of a set of known

volumetric methods by which the analysis of waters may be carried out rapidly and accurately. Since the salts present in waters are usually ionised to the extent of 70–80%, he recommends that analytical results should be stated in terms of ions, expressed as millival per litre, the millival being 1/1000 of the grm.-equivalent weight of an ion. This method has been adopted officially in Germany in returning the composition of mineral and potable waters.

—J. H. L.

Fermentation; Chemistry of alcoholic —. E. Zerner. Ber., 1920, 53, 325–334.

An account is given of experiments made in Austria-Hungary on the production of glycerol by the Connstein-Lüdecke process (this J., 1919, 691 A); some of the conclusions are at variance with those arrived at by Neuberg and Reinfurth (this J., 1920, 76 A). Equivalent amounts of acetaldehyde and glycerol are produced in the process, and, in addition, alcohol and carbon dioxide are formed, these being the only substances obtained in appreciable amount. Increase in the amount of sodium sulphite increases the yield of glycerol and aldehyde, but more than 38% of glycerol cannot be obtained. Sodium sulphite may be replaced by sodium hydro-sulphite. Failure to produce glycerol in quantitative amount by sufficiently increasing the relative proportion of sulphite has been attributed by Neuberg to dissociation of the aldehyde-bisulphite compound; this conclusion appears to be unfounded, since with moderate addition of sulphite the equivalent amount of glycerol is almost obtained, whilst with very large additions (which should have the effect of suppressing the dissociation of the aldehyde-bisulphite compound) the yield of glycerol sinks to about two-thirds of that theoretically possible. The effect seems rather to be attributable to the fact that union between aldehyde and bisulphite is not an instantaneous process, and that a certain amount of opportunity is thus offered for further degradation of the aldehyde and glycerol to alcohol and carbon dioxide. Neuberg has shown that pyruvic acid can be fermented in the presence of sulphite, but in his experiments he only used one-eighth to one-quarter of the equivalent amount of the sulphite; the use of larger proportions shows that the bisulphite compound of pyruvic acid is not fermentable, and that neither pyruvic nor glyceric acid can constitute the intermediate stage in the production of aldehyde during alcoholic fermentation. When sugar is fermented in the presence of sodium thiosulphate, sulphur is soon precipitated, hydrogen sulphide is evolved and, after a time, fermentation ceases; the yield of glycerol, reckoned on the sugar actually fermented, is very considerable. When the experiments are repeated with the addition of sodium sulphite or sodium bicarbonate, reaction proceeds as if the thiosulphate were not present. It appears, therefore, that an acid is produced during fermentation which decomposes the thiosulphate according to the equation:—

The sulphur is transformed into hydrogen sulphide by the reducing action of the yeast, whilst the sodium bisulphite combines with the aldehyde and thus provides the possibility of a good yield of glycerol. Fermentation is stopped owing to the production of organic sulphur derivatives which poison the yeast. In the presence of sulphite or carbonate the acid is neutralised by these, and the thiosulphate remains undecomposed. Generally it may be stated that glycerol and acetaldehyde are intermediate products of alcoholic fermentation which are simultaneously formed and, under normal circumstances, simultaneously disappear; as a preliminary phase an acid must be formed which, however, is not identical with pyruvic acid. During normal fermentation (without sulphite) the maximum amount of aldehyde appears to be present in the middle period of action.—H. W.

Acetaldehyde; Detection of — in alcoholic fermentation. C. Neuberg. Woch. Brau., 1919, 36, 292. J. Inst. Brew., 1920, 26, 99–100.

For the detection of acetaldehyde in fermenting liquids, 3 c.c. of the liquid is treated, without filtration, with 0.5 c.c. of 4% sodium nitroprusside solution and 2–3 c.c. of 3% piperidine solution. In presence of acetaldehyde, e.g., when fermentation is conducted in presence of calcium sulphite (see Neuberg and Reinfurth, this J., 1920, 76 A) a deep-blue coloration is produced, whilst no coloration appears in liquids fermented under normal conditions, i.e., in absence of sulphites.—J. H. L.

Sugar-beet; Fermentation experiments with —. W. Hartmann. Z. Unters. Nahr. Genussm., 1919, 38, 287–290.

BETROOT slices were heated at 70° C. with water, or treated with steam for some hours; the liquid portion was then drawn off and submitted to fermentation. A beverage was obtained which resembled beer but had a distinct, though not unpleasant, taste of beetroot. This taste was less in the beverage from the steamed beetroot and was masked to a great extent by the addition of hop extract; it is probable that treatment with steam at a high temperature would remove the beetroot taste entirely.—W. P. S.

Oxalic acid; Formation of — by *Aspergillus niger*. H. Raistrick and A. B. Clark. Biochem. J., 1919, 13, 329–344.

The production of oxalic acid by *Aspergillus niger* when grown in artificial culture media containing the salts of various organic acids as the sole source of carbon has been studied. Good growth of the fungus and good yields of oxalic acid were obtained with salts of succinic, fumaric, malic, tartaric, and acetic acids. With monobasic C_4 acids, C_5 acids, and glycollic and glyoxylic acids there was practically no production of oxalic acid, although in some cases growth was satisfactory. These results are discussed, and it is considered that the first step in the breakdown of sugar to oxalic acid is β - δ -diketoadipic acid. This undergoes hydrolysis into acetic and oxalacetic acids, the latter on further hydrolysis giving oxalic acid and acetic acid. Both molecules of acetic acid are then oxidised to oxalic acid.—J. C. D.

PATENTS.

Beer and low alcoholic malt beverages; Process of brewing —. C. A. Nowak, St. Louis, Mo. U.S. Pat. 1,328,888, 27.1.20. Appl., 13.2.18.

ORTHOPHOSPHORIC acid is added to the wort, in presence of yeast, to provide nutriment for the latter and to decompose carbonates present in the wort, and after fermentation metaphosphoric acid is added to precipitate proteins, which are subsequently removed.—J. H. L.

XIXA.—FOODS.

Gluten; Determination of wet — in low-grade flours. J. Bouyer. Bull. Soc. Pharm. Bordeaux, 1919, No. 2. Ann. Chim. Analyt., 1920, 2, 52–54.

In the analysis of low-grade flours and mixed flours it is sometimes impossible to obtain a coherent cake of gluten; disintegration during the washing process may, however, be prevented by immersing the

cake for a few seconds in ether. The washing and kneading are then continued, with further treatment with ether, if necessary.—W. P. S.

Caseinogen; Composition of —, and method for preparing esters of amino-acids. F. W. Foreman. *Biochem. J.*, 1919, 13, 378—387.

THE amino-acids obtained by the acid hydrolysis of a protein may be converted into the ethyl esters by the action of gaseous hydrogen chloride and alcohol on the dry lead salts. The process is superior to that usually employed in that there is much less loss during the manipulations which the mixture of esters undergo prior to fractional distillation. The amino-acid content of caseinogen is considered, and it is shown that some 97.36% of the molecule is now accounted for. (See further *J. Chem. Soc., Apr.*, 1920.)—J. C. D.

Cocoa [cacao] butter; Digestibility of —. J. A. Gardner and F. W. Fox. *Biochem J.*, 1919, 13, 368—377.

CACAO butter is rather less digestible than butter, and beyond a slight laxative action no undesirable physiological effects were observed to follow the administration of considerable quantities of the fat. —J. C. D.

Beans; Hydrocyanic acid content of Phaseolus lunatus —. H. Lüthrig. *Chem.-Zeit.*, 1920, 44, 166—167.

FOR the determination of hydrocyanic acid in cyanogenetic beans it is recommended that 50 grms. of the beans be steeped in water for about 18 hrs., then ground to a thin paste, acidified with tartaric acid, and steam distilled in an atmosphere of carbon dioxide; the distillate, amounting to about 400 c.c., is collected in a receiver containing dilute silver nitrate solution. The precipitate formed consists of silver cyanide, silver sulphide, etc. Ammonia is added and the mixture warmed until the silver cyanide has dissolved, the solution filtered, and the filtrate acidified slightly with nitric acid. After 18 hrs. the silver cyanide is collected, washed, dried, ignited, and the resulting metallic silver weighed. Nine samples of *Phaseolus lunatus* beans examined yielded from 5.1 to 23.4 mgrms. of hydrocyanic acid per 100 grms. Treatment with emulsin previous to distillation did not appreciably increase the yield of hydrocyanic acid. When the beans had been washed and boiled (cooked) the consumption of three quantities of 200 grms. each did not produce any poisonous symptoms. (See also Guignard, this J., 1916, 1174.)—W. P. S.

Cyanogenesis in Sudan grass. Modification of the Francis-Connell method of determining hydrocyanic acid. P. Menaul and C. T. Dowell. *J. Agric. Res.*, 1920, 18, 447—450.

THE amount of hydrocyanic acid in Sudan grass has been determined. The colorimetric method of Francis and Connell (*J. Amer. Chem. Soc.*, 1913, 35, 1624) for the determination of hydrocyanic acid has been improved, as follows: The distillate containing the hydrocyanic acid is evaporated with 1 c.c. of concentrated yellow ammonium sulphide at 170° C. The residue is heated to 130° C., dissolved in 10 c.c. of warm water acidified with hydrochloric acid, and calcium chloride solution added, drop by drop, till the sulphide ceases to form; then 10% ferric chloride solution is added until the red colour produced is permanent. The solution is filtered and 5 c.c. of ferric chloride solution added to the filtrate. By heating at 130° C. colloidal sulphur is prevented from passing into solution again, and the second addition of ferric chloride produces the maximum intensity of colour. A standard solution

of hydrocyanic acid is prepared from a solution of potassium cyanide in a similar manner, and the two solutions are compared in a Bock-Benedict colorimeter (this J., 1918, 608 A).—J. H. J.

Vitamines; Fat-soluble and water-soluble — present in green plant tissues. H. Steenbock and E. G. Gross. *J. Biol. Chem.*, 1920, 41, 149—162.

CLOVER, spinach, alfalfa (lucerne), lettuce, cabbage, and chard contain fat-soluble A. Lettuce and cabbage are not as rich in this factor as the other plants, which is in accordance with the theory that this accessory factor is associated with certain yellow plant pigments. The water-soluble vitamin is present in alfalfa, clover, and cabbage in approximately the same amount.—J. C. D.

Fat-soluble vitamin; Thermostability of — in plant materials. H. Steenbock and P. W. Boutwell. *J. Biol. Chem.*, 1920, 41, 163—171.

HEATING yellow maize, chard, carrots, sweet potatoes, or squash for three hours in an autoclave at 15 lb. pressure caused no appreciable destruction of the fat-soluble factor. The process of ensilage was also without deleterious action. It is concluded that in plant tissues the factor is comparatively thermostable.—J. C. D.

Maize silage; Role of pentose-fermenting bacteria in production of —. W. H. Peterson and E. B. Fred. *J. Biol. Chem.*, 1920, 41, 181—186.

PENTOSE-FERMENTING bacteria are capable of bringing about decided changes in raw or in sterilised maize tissue. In sterilised silage these organisms develop rapidly and produce acetic acid, lactic acid, ethyl alcohol, and carbon dioxide.—J. C. D.

Chlorine; Estimation of — in feeds, faeces, and urine. J. O. Halverson and E. B. Wells. *J. Biol. Chem.*, 1920, 41, 205—208.

THE official method of the Association of Official Agricultural Chemists (U.S.A.) is modified in that the complete washing out of the silver chloride precipitate is eliminated. Instead, an aliquot portion of the direct filtrate is titrated with ammonium thiocyanate. The solutions employed are 0.05N in strength.—J. C. D.

Chlorogenic acid. Freudenberg. See XV.

PATENTS.

Drying and thickening liquids [e.g. milk] by means of compressed air and heated air or gases. L. Galland, Berlin-Wilmersdorf. Ger. Pat. 310,192, 21.10.17.

THE liquid is sprayed in either a vertical, horizontal, or sloping direction towards a vertical current of compressed air, care being taken to prevent it entering the nozzle of the air pipe. The process is specially applicable to the drying of milk, blood, emulsions, etc.—W. J. W.

Milk and cream; Method of ascertaining the quantity of fat in —. H. M. Høyberg, Frederiksborg, Denmark. U.S. Pat. 1,329,183, 27.1.20. Appl., 2.1.19.

A MIXTURE of 97 parts by volume of the milk, 3.4 parts of an aqueous solution of potassium sodium tartrate and sodium hydroxide, and 0.6 part of isobutyl alcohol, contained in a butyrometer glass, is kept for 15—20 mins. in a water bath at 60°—70° C., and the quantity of fat is then read off directly.—J. H. L.

XIXB.—WATER PURIFICATION; SANITATION.

Water-softening process: Lime-soda —. M. R. Herrle and F. M. Gleeson. Chem. and Met. Eng., 1920, 22, 269—272.

THE effect of insufficient, correct, and excessive additions of lime and soda ash have been experimentally determined. A water of 20° hardness (c.c. standard soap solution) was reduced to 7° hardness by the addition of lime alone, and to 11° hardness by soda alone. Correct additions of lime and soda together reduced the hardness to a minimum value of 0.5°.—C. A. K.

Rivers and streams; Self-purification of —. A. E. Cooper, E. A. Cooper, and J. A. Heward. Biochem. J., 1919, 13, 345—367.

FULLY aerated sewage effluents and polluted river waters may contain considerably less dissolved oxygen than distilled water under the same experimental conditions. The low results appear to be due to various factors, and cannot be prevented by any method so far employed. As, however, the oxygen content is still the same after five days' incubation and subsequent aeration, there seems to be no appreciable error in Winkler's dissolved oxygen absorption test as modified by Rideal and Stewart (this J., 1901, 841). The oxidation of the constituents of sewage proceeds much more slowly at 10° C. than at the standard temperature of 18.3°, and it is important to adhere to a standard temperature for the test. Dilution appears to have comparatively little influence on the rate of oxidation of constituents of sewage, but the rate may be very different in waters of different geological sources. Mud from unpolluted rivers contains a considerable amount of oxidisable matter, and may have a de-oxygenating effect upon the water. In the standardisation of sewage effluents the river-water into which the effluent is actually discharged must be used for dilution in Winkler's dissolved oxygen absorption test. The oxidation by permanganate, or Tidy test, does not appear to be affected by the presence of water from different geological sources.—J. C. D.

Cresols and cresol soap substitutes; Disinfectant properties of —. E. Hailer. Arbb. Reichs-Gesundh.-Amt, 1919, 51, 556—576. Chem. Zentr., 1920, 91, II., 111.

THE disinfectant properties of cresol are diminished in alkaline solution. Such solutions are ineffective with *Staphylococcus*, but on the other hand they are active to typhus bacilli, and with *B. coli* they are not inferior to cresol soap solution. The alkaline cresol solutions are therefore suitable for use in hospitals etc.; they also have the advantage of cheapness. A mixture of equal parts of 25% sodium hydroxide and cresol diluted with 20 times its volume of water gives the best results.—W. J. W.

Poisoning by sodium fluoride. Vallée. See VII.

Brewing water. Lüers. See XVIII.

Dichloroethyl sulphide. Yablick and others. See XX.

PATENT.

Refuse destructor furnaces. A. Brechot, Paris. Eng. Pat. 133,297, 10.9.19. (Appl. 22,274/19.) Int. Conv., 30.9.18.

MATERIAL to be treated is delivered into the combustion chamber on to a bridge, whereon it is dried by hot gases from the furnace which pass above and below. It is delivered from the bridge on to the grate. The walls of the furnace immediately above the grate are inclined outwards from above down-

wards to facilitate discharge of the clinker and slag, and a conduit is formed in the walls through which the air supply for the furnace is passed to preheat it. The air passes from this conduit into the hollow grate, which is formed in two sections adapted to rock on horizontal trunnions. The air is admitted to the charge from the hollow grate through perforations, which are made tapering in cross-section. When the burning of the charge is complete the two halves of the grate are opened downwards simultaneously by means of a lever. The ash-pit is connected by a pipe to the combustion space of the furnace so that hot gas from the clinker and slag passes into the furnace. The furnace may be used for the combustion of low-grade fuel such as turf and the like.—W. F. F.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Digitalis substances. H. Kiliani. Ber., 1920, 53, 240—250. (See also this J., 1919, 477 A.)

AN account is given of some of the properties and reactions of digitaligenin, digitogenic acid, and digitoxigenin. (See J. Chem. Soc., Apr., 1920.) —H. W.

Glycogen; Colorimetric determination of —. R. Thieulin. J. Pharm. Chim., 1920, 21, 91—93.

THE method depends on the red-brown coloration produced when glycogen is treated with iodine; the intensity of the coloration is proportional to the amount of glycogen present. Two c.c. of the neutralised glycogen solution, containing from 0.05 to 0.2% of the substance, is treated with 2 drops of iodine solution (iodine, 1, potassium iodide, 2 grms., water, 20 c.c.), and the coloration is compared with that of standards containing known amounts of glycogen. It is important that 1 drop of iodine solution be used per c.c. of test solution or standard solution.—W. P. S.

Caryacrol; Fusion of sodium p-cymenesulphonate with sodium hydroxide for the production of —. H. D. Gibbs and M. Phillips. J. Ind. Eng. Chem., 1920, 12, 145—149.

BY fusing a mixture of sodium p-cymenesulphonate and sodium hydroxide in the theoretical proportions (1:2 mols.) at various temperatures for different periods, it was found that the best temperature and time are 350° C. and 6 hours respectively, a yield of 74.1% of the theoretical being obtained under these conditions. Trials with varying amounts of sodium hydroxide showed a maximum yield with a proportion of 2.2 mols. per 1 mol. of the sulphonate. When water is added to a melt to obtain a more fluid fusion the time must be increased, and higher temperatures may be employed without deleterious effect. The results demonstrate the advantages of conducting the fusion in an autoclave as compared with the use of an open pot.—S. S. A.

p-Dimethylaminobenzaldehyde; Preparation of —. T. Ingvaldsen and L. Bauman. J. Biol. Chem., 1920, 41, 145—146.

SLIGHT modifications of the process described by Ullmann and Frey (Ber., 1904, 37, 855) are used. —J. C. D.

Urea; Schiff's reaction for the detection of —. D. Ganassini. Boll. Chim. Farm., 1920, 59, 3—5.

SCHIFF'S colour reaction for the detection of urea by means of furfural (Gazz. Chim. Ital., 1877, 7, 348) is given only if the latter contains acetone as impurity. The reaction is given also by allantoin, biuret, and urethane, the colour tending to violet

with the last compound. It is rendered very sensitive as follows: A drop of the liquid to be tested is placed on a microscope slide together with a drop of concentrated nitric acid; in presence of urea, colourless overlapping rhombic or hexagonal crystals of the nitrate separate. When exposed to the vapours from a mixture of equal parts of furiurid and acetone the crystalline residue, if it is urea nitrate, becomes coloured more or less intense reddish-violet, while under the microscope the crystals are seen to be undergoing solution and to be surrounded by a pink halo.—T. H. P.

Glyoxal; Preparation of — by the action of ozone on acetylene. A. Wohl and K. Bräunig. *Chem.-Zeit.*, 1920, 44, 157.

INTERACTION of ozone and acetylene proceeds smoothly when the gases are suitably diluted with air and a certain amount of water is present, a mixture of glyoxal and formic acid being formed. By spraying water into the reaction vessel an aqueous solution is obtained containing 1.5 to 2.0 of glyoxal, and stronger concentrations can be obtained by using this solution for spraying instead of water. By converting the glyoxal into its bisulphite compound and acting on this with aniline, the anilide of anilidoacetic acid is obtained which can be used for the preparation of indigo, avoiding the acetic and chloroacetic acid stages. Alternatively, the glyoxal may be converted into glycollic acid or glycol. The original glyoxal solution contains nitric acid, formed by the action of ozone on the air, and this must be neutralised with calcium carbonate before the solution is concentrated by evaporation.—E. H. R.

Dichloroethyl sulphide [mustard gas]; Determination of — in air. M. Yablick, G. St. J. Perrott, and N. H. Furman. *J. Amer. Chem. Soc.*, 1920, 42, 266—274.

A SOLUTION of selenious acid in sulphuric acid (1:1) is reduced by traces of dichloroethyl sulphide giving an orange-red suspension of selenium; the presence of about 0.005 mgrm. of dichloroethyl sulphide can be detected in this manner. The estimation of the vapour in air is effected by bubbling the mixture through a suitable absorbent, such as a 1% solution of selenium dioxide in water, and adding 10 c.c. of a solution of selenious acid in sulphuric acid of such concentration that a 1% solution of selenious acid in 1:1 sulphuric acid is finally obtained. The solution is then heated for 10 minutes at 85° C. ($\pm 5^\circ$ C.), cooled, and the strength estimated by nephelometric comparison with standard solutions prepared from weighed quantities of the reagents. Amounts of substance between 0.1 mgrm. and 0.01 mgrm. can be determined with a maximum error of 0.005 mgrm. The selenious reagent is not specific for mustard gas; arsine and the substituted arsines and several other toxic gases react with it vigorously. (See further, *J. Chem. Soc.*, Apr., 1920.)

—H. W.

Hexamethylenetetramine; Process for making —. W. Herzog. *Z. angew. Chem.*, 1920, 33, 48.

COMMERCIAL ammonium carbonate is dissolved in 40% formaldehyde solution, the reaction taking place readily without application of heat and with brisk evolution of carbon dioxide. The solution is evaporated to dryness on a water bath under reduced pressure, and the residue is sublimed *in vacuo* or recrystallised from absolute alcohol. To compensate for its variable composition the amount of ammonium carbonate taken should be about 10% in excess of the theoretical quantity. The yield of hexamethylenetetramine is about 66% of the theoretical amount.—W. J. W.

Acetoacetic acid and its esters; Formation of β -methylumbelliferone as a reaction of —. V. Arreguine and E. D. Garcia. *Ann. Chim. Analyt.*, 1920, 2, 36—41.

WHEN 2 c.c. of concentrated hydrochloric acid containing a small quantity of acetoacetic acid is boiled for a few mins. with the addition of 0.1 grm. of resorcinol, condensation occurs with the formation of β -methylumbelliferone; the latter, after the mixture has been cooled and diluted, yields an intense blue fluorescence on the addition of a slight excess of ammonia. The reaction is not given by acetone or by β -hydroxybutyric acid; it will detect as little as 0.00001 grm. of acetoacetic acid in 5 c.c. of urine.—W. P. S.

Organic chemical reagents. V. Preparation of alkyl and alkylene bromides. O. Kamm and C. S. Marvel. *J. Amer. Chem. Soc.*, 1920, 42, 299—309.

IN the preparation of *n*-butyl bromide from the corresponding alcohol by means of hydrobromic acid, addition of sulphuric acid to the reaction mixture is of greater value than an increase in the quantity of hydrobromic acid. The Norris-Bodroux method (this *J.*, 1915, 217; 1916, 652) for preparing primary alkyl bromides has been modified in the following manner. The alcohol is treated with a 25% excess of hydrobromic acid together with some concentrated sulphuric acid. The mixture is heated under a reflux condenser, and the bromide is subsequently removed by direct distillation. The procedure is varied somewhat according to the physical and chemical properties of the alcohol used or of the bromide formed. For example, in the preparation of ethyl and allyl bromides the mixture is not heated under a reflux condenser because of the volatility of the former compound and the chemical activity of the latter; in the preparation of isoamyl bromide a somewhat smaller proportion of sulphuric acid is used in order to avoid charring; halides of high molecular weight, because of their high boiling points, are separated from the reaction mixture mechanically instead of by distillation. Detailed directions are given for the preparation of the following compounds, the corresponding yields being enclosed within brackets; *n*-butyl bromide, b.pt. 101°—104° C. (95—97%); isoamyl bromide, b.pt. 116°—120° C. (88—90%); trimethylene bromide, b.pt. 162°—165° C. (88—95%); trimethylene chlorobromide, b.pt. 142°—145° C. (89%); ethyl bromide, b.pt. 38°—40° C. (90—95%); allyl bromide, b.pt. 69°—72° C. (92—96%); *n*-octyl bromide, b.pt. 196°—200° C. (91%); lauryl bromide, b.pt. 175°—180° C. at 45 mm. (91%). The hydrobromic acid is prepared by the reduction of bromine by sulphur dioxide (Bodroux, this *J.*, 1915, 217); the mixture may be utilised directly without preliminary distillation, the necessary additional quantity of sulphuric acid being added as concentrated acid. Mixtures of constant-boiling hydrochloric and hydrobromic acids (such as are obtained when alkyl bromides are used with aluminium chloride in Friedel-Crafts syntheses) may be readily separated by fractional distillation.—H. W.

Organic chemical reagents. VI. Reagents from n-butyl alcohol. R. Adams and C. S. Marvel. *J. Amer. Chem. Soc.*, 1920, 42, 310—320.

n-BUTYL alcohol may be used for preparing *n*-amyl derivatives and *n*-caproic acid and its derivatives. Detailed instructions are given for the preparation of the following substances, the yields being placed within brackets. *n*-Butyl bromide (preceding abstract); *n*-butyl cyanide, b.pt. 138°—141° C. (75—80%); *n*-valeric acid, b.pt. 183°—186° C. (81%); ethyl *n*-valerate, b.pt. 142°—146° C. (85—90%); *n*-amylamine, b.pt. 102°—105° C. (57—68%); *n*-amyl alcohol (56—61%); ethyl *n*-butylmalonate, b.pt. 141°—145° C. at 40 mm., 235°—

240° C. at atmospheric pressure (89–92%); *n*-caproic acid, b.pt. 200°–205° C. (74%); α -bromocaproic acid, b.pt. 148°–153° C. at 30 mm. (71%); α -aminocaproic acid (65%).—H. W.

Ammonium tetroxalate, a product of the decomposition of isouanyl nitrite. H. Sandqvist and E. Mohlin. Ber., 1920, 53, 171–173.

A CRYSTALLINE deposit, needles or rods, m.pt. 129.5°–130.5° C. (decomp.), from the sides of a bottle containing commercial amyl nitrite which had become extensively decomposed, was found to consist of ammonium tetroxalate. Crystals formed under similar circumstances have been described by Böttger (Bull. Soc. Chim., 1915, [4], 17, 371), who, however, overlooked the nitrogen content and erroneously considered them to be methanetetra-carboxylic acid.—H. W.

Acetone; Analysis of — by Messinger's method. L. F. Goodwin. J. Amer. Chem. Soc., 1920, 42, 39–45.

MESSINGER's method for the determination of acetone (this J., 1889, 138) under proper conditions gives accurate and concordant results. Allowing the solutions to stand, the method of shaking and adding the iodine solution, an excess of acid, and dilution have no effect on the results. If methyl and ethyl alcohols are present they use up a certain amount of iodine.—J. F. S.

Ethylene; Nitration of —. H. Wieland and E. Sakellarios. Ber., 1920, 53, 201–210.

THE action of a nitrating acid consisting of 1 part by weight of nitric acid of sp. gr. 1.4 and 2 parts of sulphuric acid containing 20% SO_3 on ethylene at 0° C. leads to the production of glycol dinitrate, b.pt. 105.5° C. at 19 mm., sp. gr. 1.433 at 17° C., and β -nitroethyl nitrate, colourless poisonous oil, b.pt. 120°–122° C. at 17 mm., sp. gr. 1.468 at 18° C. β -Nitroethyl alcohol prepared by the action of silver nitrate on ethyleneiodhydrin is contaminated with glycol mononitrate and glycol. The purified alcohol is a colourless, odourless liquid, b. pt. 103° C. at 11.5 mm., sp. gr. 1.309 at 13.3° C. (See further, J. Chem. Soc., Apr., 1920).—H. W.

Mercury in organic combination; Method of determining — by means of zinc filings. M. François. J. Pharm. Chim., 1920, 21, 85–91.

THE method, as described previously (this J., 1913, 445, 609 A) may be applied to organic mercury compounds. The substance is dissolved by heating with alcohol, and the solution then treated with hydrochloric acid and zinc filings under the conditions given; the addition of potassium iodide is omitted. With compounds which are insoluble in alcohol the reduction with zinc may be carried out in sodium hydroxide solution to which potassium iodide is added; residual zinc is then dissolved in hydrochloric acid.—W. P. S.

PATENTS.

Tobacco; Treatment of inferior —. S. Hagino, Tokyo, Japan. Eng. Pat. 137,683, 24.3.19. (Appl. 7335/19.)

THE quality of inferior tobacco is improved by moistening the leaves with a mixture of the following liquids: an extract made by boiling resin with sodium chloride solution, an extract made by boiling pine bark with sodium bicarbonate solution, and a solution of an organic salt of iron (prepared, for example, by digesting iron oxide in vinegar).

—J. H. L.

Acetic anhydride; Manufacture of —. F. P. Leach, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 137,701, 4.4.19. (Appl. 8552/19.)

ACETIC anhydride is produced in a continuous process by the interaction of anhydrous sodium acetate and carbonyl chloride, according to the equation, $2\text{CH}_3\text{CO}_2\text{Na} + \text{COCl}_2 = (\text{CH}_3\text{CO})_2\text{O} + \text{CO}_2 + 2\text{NaCl}$. The reaction is started by suspending sodium acetate in acetic anhydride and adding alternately, with cooling, carbonyl chloride and sodium acetate, keeping the latter in slight excess until the desired quantities have been mixed. A portion of the mixture is then run off into a still and the acetic anhydride distilled off in a vacuum, whilst fresh quantities of sodium acetate and carbonyl chloride are added to the mixture remaining in the reaction vessel.—G. F. M.

Iodine dusting powder and process for making same. N. Sulzberger, New York. U.S. Pat. 1,329,148, 27.1.20. Appl., 14.10.15.

AN antiseptic dusting powder is made by treating boric acid with a solution of iodine in a suitable solvent and then evaporating the solvent.—J. H. L.

Aromatic amines; Production of —. E. C. R. Marks, London. From E. I. du Pont de Nemours and Co., Wilmington, Del., U.S.A. Eng. Pat. 138,372, 18.7.17. (Appl. 10,374/17.)

UNSUBSTITUTED poly-arylamines are formed by heating at about 300° C. unsubstituted monoaryl amines in the presence of 0.5–3% of a catalyst containing a halogen, such as an ammonium halide, ferrous chloride, magnesium bromide, chloro- or bromo-benzene, aniline hydrochloride, etc. The reaction is facilitated by the presence of not more than 2% of water. For example, aniline is heated with 1% of ferric chloride for 48 hours at 300° C. in an autoclave provided with a vertical column having a release valve at its apex, through which the ammonia is removed from time to time. The reaction product is fractionated, the lower fractions being returned to the autoclave for redigestion, whilst the fraction boiling above 300° C. consists mainly of diphenylamine, and a tarry residue remains behind in the still.—G. F. M.

Mono- and di- β -hydroxyethylaminobenzoic esters; Manufacture of —. Soc. Chim. des Usines du Rhône, Paris. Eng. Pat. 128,552, 30.5.19. (Appl. 13,760/19.) Int. Conv., 20.6.18.

MONO- and di- β -hydroxyethylaminobenzoic esters are obtained by heating to temperatures varying from 50° to 110° C. a mixture of ethylene oxide (1–2 mols.) and an aminobenzoic ester (1 mol.). The reaction can be accelerated by the addition of small quantities of water or ethyl alcohol. Thus ethyl β -hydroxyethyl-*p*-aminobenzoate, $\text{OH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NHC}_6\text{H}_4\cdot\text{CO}_2\text{C}_2\text{H}_5$, a colourless, crystalline substance, m.pt. 63° C., is produced by heating for several hours in a closed vessel at 50° C. equimolecular proportions of ethylene oxide and ethyl *p*-aminobenzoate; whilst if under similar conditions 2 mols. of ethylene oxide are used together with $\frac{1}{2}$ mol. of water and 1 mol. of ethyl alcohol, ethyl di- β -hydroxyethyl-*p*-aminobenzoate is formed. After crystallisation from benzene it forms white lamellae, m.pt. 94° C.—G. F. M.

Bromoacylized urea compounds; Manufacture of derivatives of —. Farbenfabr. vorm. F. Bayer und Co., Leverkusen, Germany. Eng. Pat., 132,795, 16.9.19. (Appl. 22,766/19.) Int. Conv., 9.8.17.

ON treating bromoacylized urea compounds with acylising agents in presence of condensing agents such as zinc chloride or sulphuric acid, acyl compounds are obtained which have a rapid but lasting sedative and soporific action. Examples are given

of the preparation of acetyl bromodiethylacetylurea, m. pt. 108° — 109° C., from bromodiethylacetylurea (174 parts), acetic anhydride (1000 parts), and zinc chloride (75 parts), the mixture being heated for one hour at 60° C. and then poured into iced water (3000 parts); of acetyl bromoisovalerylurea, m. pt. 108° — 109° C., from bromoisovalerylurea and acetic anhydride; of propionyl bromodiethylacetylurea, m. pt. 103° C., and of benzoyl bromodiethylacetylurea, m. pt. 139° — 140° C., sulphuric acid being employed as condensing agent in each of the latter three examples.—G. F. M.

Dihydroxy - diamino - arseno - benzol - dihydrochloride; Sodium compound of —. C. Suzuki, Tokyo, Japan. U.S. Pat. 1,330,288, 10.2.20. Appl., 7.6.16.

A SOLUTION of sodium alcoholate (ethoxide) is mixed with a solution of dihydroxydiaminoarsenobenzene dihydrochloride, and the resulting sodium compound precipitated by the addition of ether.

—B. V. S.

Saponin or similar substances; Production of — from vegetable extracts rich in sugar or colouring matters. Billwärders Seifen- u. Glycerinfabr. W. Krauss and W. H. Hofmann, Hamburg. Ger. Pat. 314,877, 23.5.18.

AQUEOUS or alcoholic vegetable extracts are treated at 60° C. with aqueous solutions of alkali or alkaline-earth hydroxides until the reagent is in slight excess, and then a mineral acid or an acid salt is added to cause precipitation. The precipitate can be purified by treatment with reducing bleaching agents. The effect of the preliminary treatment with alkali is to double the yield of precipitate, which is deposited as a fine flocculent mass. The precipitate contains saponin in a fairly pure form, and a higher degree of purity can be attained by repeating the solution in alkali and re-precipitation with acid. Decolorisation of the first precipitate can be effected with reducing bleaching agents, e.g., hydrosulphites, sulphurous acid, or sulphites, followed by acidification with mineral acids. The slightly soluble saponin becomes soluble if just sufficient calcined soda is added to cause the dissolved mixture to react slightly alkaline.—H. J. H.

Acetic acid; Concentration of solutions of —. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 314,943, 26.8.16.

ACETIC acid containing bisulphate in solution is extracted with ether. The equilibrium concentration of acetic acid in ether when in contact with the bisulphate solution is almost double that attained in the absence of bisulphate, while only traces of ether are dissolved in the bisulphate solution. The extraction process is also accelerated. On distilling the ether off, a residue of 70—80% acetic acid is obtained from which glacial acetic acid can be fractionated, the fore-runings being returned to the extraction process.—H. J. H.

Penetration of electrolytes into gels. Stiles. See XV.

Turbidimeter for gelatin etc. Sheppard. See XXIII.

PATENTS.

Non-inflammable films or filaments for kinematographic and other industrial purposes; Manufacture of —. W. J. Stevenson, London. Eng. Pat. 138,379, 21.8.18. (Appl. 13,569/18.)

A NON-INFLAMMABLE, impermeable, durable, flexible, and transparent film is obtained from a solution

of cellulose acetate, preferably in tetrachloroethane or benzyl alcohol, containing also triacetin and triphenyl phosphate; the amounts of the two latter are about equal and may vary from 10% to 30% of the weight of the cellulose acetate.—B. V. S.

Coloured photographs or kinematograph films; Producing —. W. Finnigan, London, and R. A. Rodgers, Hove. Eng. Pat. 138,396, 7.1.19. (Appl. 120/19.)

A NEGATIVE is taken through a translucent colourless screen, such as ground glass, in contact with the sensitive film, and a print is obtained from this negative on a sensitised material provided with a coloured dotted screen film between the base and the sensitive film.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; Notes on the German stability tests and on a new hot storage test (75° C.) for —. F. Lenze and B. Pleus. Z. ges. Schiess- u. Sprengstoffw., 1919, 14, 297—299, 315—318. Chem. Zentr., 1920, 91, II., 107.

TESTS with samples of nitrocellulose from various sources and which had been subjected to different methods of purification proved that the manometric and nitric oxide methods did not give sufficient indication of the degree of stability. The use of a bath with a liquid of constant boiling point, such as carbon tetrachloride (75° C.), gives good results.—W. J. W.

Mercury fulminate; By-products in the preparation of —. A. Langhaus. Z. ges. Schiess- u. Sprengstoffw., 1919, 14, 300—304, 318—321, 334—337, 350—353. Chem. Zentr., 1920, 91, II., 106, 107.

THE CONDENSATION liquors contain approximately twenty times as much mercury as the mother liquor. The acidity varies inversely with the mercury content. Control tests of the amount of mercury are made by an electrolytic method; a platinum basin must be used. Mercury settles out from the condensation liquors after 24—48 hours' standing, and in the receivers after 1 day. In the quantitative estimation of the mercury as mercurous chloride hydrogen chloride must not be present in excess, and solution of the mercurous chloride depends on the nitric acid concentration. Mercury in the condensation liquors may also be readily titrated with sodium hypochlorite. The precipitation of chloride from the liquors and neutralisation of these may be carried out simultaneously in one vessel by using sodium chloride solution and soda instead of hydrogen chloride and lime, but the method is more expensive. With lime some lime is always precipitated, or a double compound of lime and mercurous oxide may be formed. Four-fifths of the liquors are volatile, and the residue is explosive. (See also this J., 1919, 442 A.)—W. J. W.

PATENTS.

Explosives. C. Mammelli and L. Bernardini, Rome. Eng. Pat. 138,371, 17.7.17. (Appl. 10,328/17.)

EXPLOSIVE products are obtained by melting together ammonium nitrate and guanidine nitrate or biguanide nitrate, or ammonium nitrate and dicyanodiamide, with or without the addition of nitroguanidine, in such proportions that the product melts below 130° C. Good explosive mixtures are obtained by melting, for example, ammonium nitrate 6—8, dicyanodiamide 0.6—0.8, and nitroguanidine 1.2—2.5 parts by weight. The mixture has high explosive power and great stability, is completely homogeneous, and may be safely handled.—T. St.

Colloid bodies [smokeless powders]; Preparation of —. W. O. Snelling, Allentown, Pa. U.S. Pat. 1,305,946, 3.6.19. (Appl., 14.8.17.

SMOKELESS powder is prepared by mixing nitro-starch with an agent, *e.g.*, liquid trinitrotoluene, which does not gelatinise the nitro-starch during the mixing process, and subsequently heating the mixture to 60°–90° C., to cause "colloidisation" (gelatinisation).

Explosive; Preparation of an —. R. Mewes, Berlin. Ger. Pat. 301,796, 26.2.16.

A COMPOUND of oxygen and nitrogen, with or without chlorine, and in either the liquid or solid state, is mixed with a non-combustible absorbent such as ferric chloride. This mixture is conveyed in suitable containers, in bulk or in cartridge form, to the place where it is to be employed, and a liquid combustible material is there added to it immediately before use.—W. J. W.

Hexanitrotriphenyl phosphate; Production of —. Imhansen und Co., and K. Lehmstadt, Witten. Ger. Pat. 302,501, 20.3.17.

TRIPHENYL phosphate is nitrated with mixed nitric and sulphuric acids or nitric and phosphoric acids. The former mixture at 50°–60° C. gives *p*-trinitrotriphenyl phosphate, and at 80° C. a good yield of the 2,4-hexanitrotriphenyl phosphate. The latter is not sensitive to shock and so is a serviceable explosive. More prolonged nitration at higher temperature gives picric acid sufficiently pure for use.—H. J. H.

Propellant charges containing ammonium nitrate. Verein. Köln-Rottweiler Pulverfabriken, Berlin. Ger. Pat. 303,979, 27.6.17.

To reduce the pressure necessary for forming charges of which ammonium nitrate is an ingredient, and also to avoid evolution of smoke on firing, a mixture of wood charcoal, 2 parts, and lampblack, 1 part, is added to the composition. The lampblack serves further to prevent decomposition of the pressed charges during drying and enables them to sustain a temperature of 35° C. without fracture. To prevent absorption of moisture wood tar may be added to the composition, or the charges may be encased in a protecting composition of nitroglycerin, nitrocellulose, and a eutectic solution of tri- and dinitrotoluenes.—W. J. W.

Explosives; Manufacture of — in a form in which they can be poured. Sprengstoff A.-G. Carbonit, Hamburg. Ger. Pat. 307,040, 4.8.17.

Two metallic nitrates are mixed together in non-molecular proportions and heated to a temperature well below the melting point of either of them. A halogen salt or urea may be added, as well as nitro compounds to increase the power of the explosive. If urea is added, one nitrate only may be used. Typical compositions are: (1) Ammonium nitrate, 90; sodium nitrate, 10 parts. (2) Ammonium nitrate, 90; sodium nitrate, 5; and sodium chloride, 5 parts. (3) Ammonium nitrate, 37.5; urea, 6.25; sodium chloride, 6.25 parts.—W. J. W.

Nitrocellulose; Manufacture of —. Vereinigte Köln-Rottweiler Pulverfabriken, Berlin. Ger. Pat. 307,120, 25.4.18.

INSTEAD of washing the nitrocellulose by displacing the nitration acids with water, the nitrocellulose is caused to travel slowly through the layer of water. Risk of mixing acids and water is thus eliminated.—W. J. W.

Explosives; Manufacture of — from hexanitrodiphenylamine and trinitrotoluene. O. von Schroetter, Oberlössnitz-Radebeul. Ger. Pat. 315,306, 3.2.12.

HEXANITRODIPHENYLAMINE is added to molten trini-

tritoluene to form an explosive mixture, which, on account of its greater density, is more active and less liable to disintegration at higher temperatures than the product obtained by mixing the components and subsequent compression of the mixture, and is also superior in regard to susceptibility to shock or percussion.—L. A. C.

Explosive mixtures. Atlas Powder Co., Wilmington, Del., Assignees of R. L. Hill and A. J. Strane, Tamaqua, Pa., U.S.A. Eng. Pat. 131,524, 1.9.19. (Appl. 21,139/19.) Int. Conv., 1.11.18.

SEE U.S. Pat. 1,299,942 of 1919; this J., 1919, 480 A.

XXIII.—ANALYSIS.

Condensers [; Laboratory —]. F. Friedrichs. Z. angew. Chem., 1920, 33, 29–32.

THE various forms of laboratory condensers devised since the time of Liebig are discussed, and forty-five references to literature are given. The most efficient condenser appears to be the screw-form tube with five threads and internal cooling; this form has also advantages over the spiral form condenser when used for reflux purposes.—W. P. S.

Viscosity measurements. O. Faust. Z. physik. Chem., 1919, 93, 758–761.

VISCOSITY measurements, by the method of noting the time taken by an air bubble in rising through a measured vertical column of liquid, are best made with tubes 24–18 mm. diameter. In these tubes the time is independent of the size of the bubble and the diameter of the tube. (See also J. Chem. Soc., 1920, ii., 166.)—J. F. S.

Analysis; Method of stating the results of —. A. Thiel. Chem.-Zeit., 1920, 44, 31–32.

It is suggested that the results of analysis be expressed in equivalent-units per 100 grms. or 100 c.c. of the original substance.—W. P. S.

Turbidimeter for solutions of gelatin, cellulose, and varnishes. S. E. Sheppard. J. Ind. Eng. Chem., 1920, 12, 167–169.

FOR dealing with limited quantities of liquids an apparatus is described which operates with small constant thicknesses of liquid and comprises two superposed opaque line gratings arranged to rotate relatively to each other (Ives, Elect. World, 1910, 939; J. Opt. Soc. Amer., 1917, 100). Viewed by transmitted light, at such a distance that the grating lines are below the limit of resolution, parallel dark bands are seen. If a scattering, turbid medium be placed in front of the crossed gratings, the visibility limit can be measured by the angle through which the gratings must be turned to make the bands just disappear. Readings with an instrument constructed on this principle can be made as rapidly as with a polarimeter or refractometer, and the result can be expressed as percentage clarity referred to a given thickness of a standard medium, such as distilled water or lacquer solvent.—S. S. A.

Tin salts; Reaction of —. A. Mazuir. Ann. Chim. Analyt., 1920, 2, 9.

WHEN 2 c.c. of a neutral or alkaline solution of a stannic or stannous salt is mixed with 2 c.c. of 10% potassium iodide solution and 2 c.c. of concentrated sulphuric acid is added, a yellow crystalline precipitate of tin iodide is obtained. The precipitate is soluble in chloroform, alcohol, and dilute hydrochloric acid and is decomposed by ether with the liberation of iodine. Arsenic and antimony salts yield a similar reaction, but the arsenic iodide is quite insoluble in hydrochloric acid and the

antimony iodide forms a brick-red flocculent precipitate. Other metals of the antimony group do not interfere with the reaction.—W. P. S.

Lead and bismuth; Separation and determination of —. G. Luff. *Chem.-Zeit.*, 1920, 44, 71.

A nitric acid solution of the two metals is treated with ammonia, added drop by drop, until a slight turbidity forms; this is dissolved by the addition of a few drops of nitric acid, saturated ammonium nitrite solution and sodium nitrite solution are added, the mixture is diluted to about 200 c.c., and heated to boiling; when nitrogen ceases to be evolved, the precipitate of bismuth hydroxide and basic nitrate is collected on a filter, washed with hot water, then dissolved in nitric acid, the solution evaporated and the residue ignited and weighed as Bi_2O_3 . The ignited oxide is treated with nitric and hydrofluoric acids to remove silica, then washed to remove traces of alkali, and again weighed. The filtrate from the bismuth precipitate is acidified with acetic acid and the lead precipitated and weighed as chromate. With modification, the method may be used for the separation of bismuth and cadmium.—W. P. S.

Calcium and magnesium; Estimation of — in different saline media. E. Canals. *Bull. Soc. Chim.*, 1919, 25, 655–658. (See this J., 1919, 159 A, 797 A.)

For the volumetric estimation of small amounts of magnesium it is recommended that the magnesium should first be precipitated as magnesium ammonium phosphate and then one of the two following methods adopted. The precipitate is washed centrifugally with dilute ammonia solution and then dissolved in just sufficient 5% hydrochloric acid, the phosphoric acid in this solution being estimated by titration with an uranium solution (1 c.c. = 0.5 mgrm. P_2O_5), using cochineal as an indicator; or, the precipitate is washed with a saturated aqueous solution of sodium phosphate and then dissolved in hydrochloric acid, the ammonia present being estimated colorimetrically by means of Nessler's reagent. The results are accurate to 0.2 mgrm. of magnesium by the first and to 0.01 mgrm. by the second method.—W. G.

Manganese; Sensitive reaction for —. P. H. Hermans. *Pharm. Weekblad*, 1919, 56, 1344–1346.

CARON and RAQUET's reaction (this J., 1919, 574 A), in which a red coloration is produced by oxidising agents in manganese solutions after addition of potassium oxalate and acetic acid, was discovered independently by the author, and incidentally employed as a test for nitrogen tetroxide in presence of chlorine and bromine. It may also be used for the detection of nitrites. Suitable oxidising agents are potassium permanganate and bichromate, lead peroxide, nitrous acid, nitrogen tetroxide, etc. Some substances, although in themselves powerful oxidising agents, have a negative effect, but can be made effective by addition of osmic acid. Such are hydrogen peroxide, potassium persulphate, chlorine, bromine, iodine, chloric acid, iodic acid, and potassium ferricyanide. For the manganese test, lead peroxide is most suitable, as it is stable and gives no coloration alone. The test is sufficiently sensitive to indicate 0.07 mgrm. manganese, or 0.03 mgrm. sodium nitrate, in 1 c.c. of solution. The red coloration is due to formation of a complex alkali manganese oxalate.—W. J. W.

Cadmium vapour arc lamps. Bates. See IIa.

Phenol. Fischer and Breuer. See III.

PATENTS.

Furnace-gases; Apparatus for ascertaining the composition of —. [Determination of carbon dioxide.] F. Cossor, London. Eng. Pat. 138,156, 23.1.19. (Appl. 1716/19.)

A MEASURING vessel of known capacity is connected to the furnace-flue by way of a hand-controlled stop-valve, and also to a closed vessel containing a solution of caustic potash through which the gas from the measuring vessel is caused to pass. A vertical tube, having a capacity fully equal to that of the measuring vessel, depends from the latter, and is connected by a U-tube to a reservoir of inert liquid (glycerin and water), the level of which coincides with the bottom of the depending tube; and an indiarubber pumping-ball is connected to the upper end of the reservoir through a tube provided with a venting plug and a non-return valve. The gas outlet of the absorption vessel communicates with a hand-controlled vent and with one limb of a manometer, the other limb of the latter being open, graduated, and extending at a slight upward inclination to the horizontal.—W. E. F. P.

Soluble gas constituents; Apparatus for determining —. F. W. Sperr, jun., Oakmont, Pa., and A. A. Kohn, Newark, N.J., Assignors to The Koppers Co., Pittsburgh, Pa. U.S. Pat. 1,316,602, 23.9.19. Appl. 3.12.18.

THE apparatus comprises two concentric chambers, connected in series and a coil in each chamber immersed in a gas-absorbing liquid therein, the length of the coil being greater than the depth of the liquid in which it is immersed. The gas under examination is passed through an injector jet into the lower end of one coil, and the injector action causes circulation of the absorbing liquid through the coil. The gas is afterwards passed in a similar manner through the other coil to remove the last traces of the soluble constituent.

Calculations depending on the relations between the pressures, densities, temperatures, and percentage compositions of gases; Instrument for facilitating — and recording of observations of these quantities. P. G. N. Ommaney, Westminster. Eng. Pat. 138,146, 7.1.19. (Appl. 484/19.)

Fat in milk. U.S. Pat. 1,329,183. See XIX A.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Aktieselskabet Myrens Verksted. Apparatus for drying solid moist substances. 8340. Mar. 20. (Norway, 7.2.18.)

Beeton, and Trufood, Ltd. Drying organic substances. 9044. Mar. 27.

Christie. Driers. 7966. Mar. 17.

Cloke and Smith. Separating and/or concentrating materials. 8591. Mar. 23.

Davies. Emulsifiers. 8954. Mar. 26. (U.S., 23.4.17.)

Ellerm (Ruzicka). Effecting reactions between gases and/or vapours. 8933. Mar. 26.

Fairweather (Aktiebolaget Kväveindustri). Heat treatment of masses or liquids by gases. 7978. Mar. 17.

Galvanizing Equipment Co., and Lane. Furnaces. 8059. Mar. 18.

Head. Roasting or calcining furnaces etc. 8901. Mar. 26.

Larsen. Burning watery materials in kilns. 8485. Mar. 22. (Denmark, 4.6.19.)

Martin and Richards. 8573. See X.

Merz. Evaporation of liquids with recovery of the vapours. 7778. Mar. 16.

Peters. Crystallising-pans. 8345. Mar. 20.

St. Barbe. Briquettes and process of making same. 7788. Mar. 16.

St. Barbe. Binding loose material for briquettes, road surfaces, etc. 7789. Mar. 16.

Sturgeon. Centrifugal separating-apparatus. 8091. Mar. 18.

Syndicaat Electro-Staal, and Vermaes. Rotary kilns. 7713. Mar. 15.

Waterhouse, and Waterhouse, Ltd. Manufacture of crucibles etc. 8046. Mar. 18.

Worthington Pump and Machinery Corporation. Filter press. 8798. Mar. 25. (U.S., 9.3.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

18,471 (1914). Chantraine. Furnaces. Mar. 24.
18,473 (1914). Chantraine. Furnaces. Mar. 31.
10,455 (1918). Elektro-Osmose A.-G. Electro-osmotic process for removing water from materials. (135,817.) Mar. 24.

20,765 (1918). O'Brien. Continuous fractional distillation. (140,140.) Mar. 31.

21,927 (1918). Boland. Drying process and apparatus. (140,145.) Mar. 31.

4967 (1919). Lessing. Rings for filling absorption towers, distilling columns, etc. (139,880.) Mar. 24.

22,076 (1919). British Thomson-Houston Co. (General Electric Co.). Catalyzing material. (140,011.) Mar. 24.

367 (1920). Delaygne. Solution for absorption refrigeration processes. (140,356.) Mar. 31.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Bean. Method of producing gas. 8256. Mar. 19.

Carpenter. Purification of coal gas etc. 8699. Mar. 24.

Engelke. 9050. See III.

Field. Coal substitute. 7658. Mar. 15.

Franklin. Fuel. 8971. Mar. 26.

Good Inventions Co. Combustion of liquid etc. fuel. 8270. Mar. 19. (U.S., 6.6.16.)

Hart. Production of carbon from waste materials etc. 8718. Mar. 24.

Hislop. Fuel. 7783. Mar. 16.

International Coal Products Corp. Manufacture of briquettes. 8955. Mar. 26. (U.S., 18.2.18.)

Kormann. 7994. See XII.

Lund. Gas producers etc. 9010. Mar. 27.

Pfeifer. Production of gas etc. 8327. Mar. 20.

Poppe. 7998. See IX.

St. Barbe. 7788 and 7789. See I.

Smith, and Whitehall Petroleum Corp. Oil-distilling apparatus etc. 8104. Mar. 18.

Smith and Tulloch. Gas producers. 8593. Mar. 23.

Thompson. Furnaces for manufacture of gases etc. 8949. Mar. 26. (U.S., 1.6.18.)

Trotter. Production of gasoline. 7956. Mar. 17.

U.S. Industrial Alcohol Co. Liquid fuels. 8797. Mar. 25. (U.S., 12.10.17.)

Wade (Standard Oil Co.). Distilling petroleum. 8361. Mar. 20.

Williams. Manufacture of gas-purifying material. 8279. Mar. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

987 (1918). Bouillon. Dehydrating peat. (140,112.) Mar. 31.

16,820 (1918). Soc. de Chimie et Catalyse Industrielles. Production of rich gases from petroleum residues. (140,128.) Mar. 31.

3916 (1919). Smith. Gasification of coal. (123,738.) Mar. 31.

12,923 (1919). Bildt. Producer-gas furnace. (139,957.) Mar. 24.

14,848 (1919). Steel. Manufacture of fuel from anthracite duff. (139,977.) Mar. 24.

26,395 (1919). Vickers and Dickson (Clayton). Composite fuel. (140,025.) Mar. 24.

III.—TAR AND TAR PRODUCTS.

APPLICATION.

Engelke. Treating hydrocarbon oils, tars, asphalts, etc. 9050. Mar. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

15,440 (1919). Burt, Boulton, and Heywood, and Miles. Manufacture of carbazole. (139,981.) Mar. 24.

21,360 (1919). Morris and Co., and Morris. Sulphonation and chlorination of aromatic substances. (140,007.) Mar. 24.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

Ges. f. Chem. Ind. in Basel. Manufacture of substantive *o*-oxyazo dyestuffs, copper compounds thereof, and their application in dyeing. 8920. Mar. 26. (Switz., 1.5.19.)

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bouillon and Worms. Apparatus for producing cellulose threads. 7634. Mar. 15.

British Cellulose and Chemical Manuf. Co., Briggs, Clotworthy, and Dreyfus. Manufacture of fibres and fabrics. 7929. Mar. 17.

British Cellulose and Chemical Manuf. Co., and Roy. Production of artificial filaments. 8880. Mar. 26.

Bronnert. Manufacture of viscose silk. 8000 and 8451. Mar. 17 and 22.

Fort, Lumsden, Mackenzie, and Robinson. Scouring vegetable yarns and fabrics. 8972. Mar. 26.

Goldberg. Protecting from fire inflammable substances. 7792. Mar. 16. (Ger., 27.6.19.)

Hart. Degumming ramie fibre. 8599. Mar. 23.

Langwell and others. 8115. See XVIII.

Minton. Drying paper etc. 8908—8911. Mar. 26.
 Paul. Recovery of grease from waste liquors from wool-scouring. 8766. Mar. 25.
 Soc. la Soie Artific. de la Voulte. Waterproofing and strengthening threads and fabrics. 9056. Mar. 27. (Fr., 11.2.20.)

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Fort, Lumsden, Mackenzie, and Robinson. Scouring and bleaching yarns etc. composed of vegetable fibres containing dyed effect threads or fibres. 8366. Mar. 20.
 Ges. f. Chem. Ind. in Basel. 8920. See IV.
 Tootal. Dyeing. 8391. Mar. 22.
 Vallays. Dyeing-vats. 7811. Mar. 16. (Fr., 21.3.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

7094 (1919). Saundevan, Ltd., and Evans. Fireproofing fabrics. (110,209.) Mar. 31.
 8360 (1919). Sharp. Means of fastening dyes in material, and waterproofing same. (110,222.) Mar. 31.
 14,599 (1919). Gaston and Rushton. Dye jigs. (139,971.) Mar. 21.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Enderli. Manufacture of formates. 7922. Mar. 17.
 Greatham. Extraction of potash from blast-furnace dust and recovery of metalliferous residue. 8380. Mar. 22.
 Nitrogen Corporation. Production of nitrogen compounds. 7665. Mar. 15. (U.S., 1.9.17.)
 Nitrogen Corporation. Production of ammonia. 7967. Mar. 15. (U.S., 17.3.19.)
 Poppe. 7998. See IX.
 Soc. Anon. l'Azote Français. Manufacture of ozone. 8471. Mar. 22. (Switz., 22.3.19.)
 Wilderman. Production of hypochlorites and chlorates. 7832. Mar. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

7661 (1918). Hulin. Preparation of anhydrous metallic chlorides. (110,114.) Mar. 31.
 17,991 (1919). Barnes. Preparation of barium hydroxide from barium sulphide. (110,297.) Mar. 31.
 21,939 (1919). Barbe. See XVI.
 25,676 (1919). Salzwirk Heilbronn A.-G. Process for making sodium sulphate. (131,214.) Mar. 31.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Central School of Science and Technology, Imperial Trust, Mellor, and Moore. Manufacture of pottery etc. 8336. Mar. 20.
 Hancock. Manufacture of pottery and porcelain. 8747. Mar. 25.
 Marlow. Gas-fired ovens or kilns for tiles, pottery, etc. 8037. Mar. 18.
 Saavedra. Vitrefied product. 8183. Mar. 22.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Buckle. Manufacture of bricks. 8255. Mar. 19.
 Cochrane. Manufacture of cement from blast-furnace slag. 8761. Mar. 25.
 Fabriks Aktiebolaget Kronsten. Insulating and building material. 7901. Mar. 17. (Sweden, 19.3.19.)
 Kirkpatrick and Monnoyer. Manufacture of compositions for covering roads etc. 8001. Mar. 17.
 Poppe. Utilisation of combustion gases of brick etc. ovens, and manufacture of sulphurous products. 7998. Mar. 17.
 St. Barbe. 7789. See I.

St. Barbe. Manufacture of binders for road-making etc. materials. 7790. Mar. 16.
 Smith. Manufacture of concrete blocks, briquettes, etc. 7818. Mar. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

16,530 (1914). Mellersh-Jackson (Krupp A.-G.). Manufacture of Portland cement. Mar. 31.
 14,789 (1919). Lambert. Hardening and preserving permeable soft woods. (139,974.) Mar. 21.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Annable. Extraction of copper from its ores. 7791. Mar. 16.
 Blair. Open-hearth furnaces. 7986 and 8098. Mar. 17 and 18. (U.S., 12.9.16 and 20.7.17.)
 Blanch. Manufacture of tungsten from its ores. 7618. Mar. 15.
 British Thomson-Houston Co. (General Electric Co.). Treatment of metals. 8213. Mar. 19.
 Champion. Cast-iron welding flux. 7657. Mar. 15.
 Clark, and Metallurgical Plant Construction Co. Heat treatment of metallic etc. objects. 8079. Mar. 18.
 Cochrane. 8761. See IX.
 Conroy, and Harper, Sons, and Bean. Furnace for tinning etc. 7771. Mar. 16.
 Duke. Alloys. 8701. Mar. 21.
 Edser and Wood. Concentration of ores by flotation. 8359. Mar. 20.
 Greatham. 8380. See VII.
 Hadfield. Manufacture of steel. 8103. Mar. 18.
 Marks (Scovill Manuf. Co.). Melting and reducing metals. 7663. Mar. 15.
 Martin and Richards. Treatment of pulverulent or granular material with gases, particularly roasting of ores etc. 8573. Mar. 23.
 Mathys (U.S. High Speed Steel and Tool Corp.). High-speed tool material. 8728. Mar. 24.
 Metallbank u. Metallurgische Ges. Bearing metals. 8727. Mar. 21. (Ger., 18.1.17.)
 Moeller and Schwere. Extraction of metals from complex ores. 8019. Mar. 18.
 National Malleable Castings Co. Steel. 8956. Mar. 26. (U.S., 21.5.15.)
 National Malleable Castings Co. Alloyed steels 8957. Mar. 26. (U.S., 21.5.15.)
 National Malleable Castings Co. Preparing iron for castings. 8962. Mar. 26. (U.S., 17.11.15.)
 Preston. Colouring metal. 7751. Mar. 16.
 Stock. Production of metals in electric furnace. 8719. Mar. 21.
 Sulman. Treatment of low-grade garnierite ores. 8268. Mar. 19.
 United Lead Co. Hard lead alloys. 8960. Mar. 26. (U.S., 2.10.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

12,590 (1917). Krupp A.-G. Grusonwerk. Treatment of ores. (109,271.) Mar. 31.
 5811 (1918). Gontermann. Basic Bessemer process for producing steel. (115,027.) Mar. 31.
 2288 (1919). Boisselier. Solder for aluminium. (121,715.) Mar. 21.
 10,132 (1919). Cunningham, and Stein and Atkinson. Furnaces for heat treatment of metals. (110,238.) Mar. 31.
 13,597 and 17,785 (1919). Leathart, and Locke, Blackett, and Co. Refining lead. (140,278.) Mar. 31.
 14,111 (1919). Cunningham. Preparing aluminium or its alloys for electro-plating. (139,967.) Mar. 21.
 17,573 (1919). Wale and Wale. Composition for coating metals with tin or tin alloys. (110,294.) Mar. 31.
 23,746 (1919). Soc. des Alliages et Bronzes Forgeables. Tilting crucible or melting-pot furnaces. (110,015.) Mar. 21.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Beswick. Electric storage batteries. 8065. Mar. 18.

Marks (Scovill Manuf. Co.). Electric furnaces. 7664. Mar. 15.

Scovill Manuf. Co. Automatic control mechanism for electric furnaces. 8711. Mar. 24. (U.S., 26,618.)

Soc. Métallurgique du Frayol. Electric furnaces. 8444. Mar. 22. (Fr., 7,120.)

Stock. 8719. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

10,455 (1918). Elektro-Osmose A.-G. *See* I.

14,106 (1918). Jungner. Primary galvanic batteries with unalterable electrolyte. (118,843.) Mar. 31.

20,375 (1918). Imbery. Electric muffle furnaces. (140,138.) Mar. 31.

21,831 (1918). Fenton. Electric furnaces. (139,843.) Mar. 24.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Arlt. Apparatus for separating oil or fat. 8805. Mar. 25.

Kormann. Treating oil. 7994. Mar. 17.

Paul. 8766. *See* V.

Quick. Treatment of animal and vegetable oils. 8354. Mar. 20.

Rankin and Self. Extraction of oils, fats, alkaloïds, etc., by volatile solvents. 7803. Mar. 16.

COMPLETE SPECIFICATION ACCEPTED.

6142 (1919). Naaml. Vennoots. A. Jurgens' Vereen. Fabr. Recovering oils and fats from soap-free waste water. (124,220.) Mar. 24.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATION.

British Thomson-Houston Co. (General Electric Co.). Protecting-compositions. 7944. Mar. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

290 (1919). Flakes A/S., and Schou. Manufacture of painting and priming compositions. (140,147.) Mar. 31.

18,392 (1919). Barbe. Manufacture of a white pigment. (140,301.) Mar. 31.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Allenet et Cie. Vulcanising rubber. 8117. Mar. 18. (Fr., 15,120.)

Tudor (Tudor). Utilisation of waste rubber. 8810. Mar. 25.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Bray (Indian Wood Products Co.). Manufacture of catechin and catechu tannic acid. 8681. Mar. 24.

Knudsen. Tanning fish skins. 8416. Mar. 22.

Knudsen. Manufacture of fish glue and isinglass. 8417. Mar. 22.

Marris, and Walker and Sons. Process for tanning. 8861. Mar. 26.

Ross, and Walker and Sons. Epilation of skins. 8739. Mar. 25.

COMPLETE SPECIFICATION ACCEPTED.

7479 (1918). Weiss. Manufacture of horny masses from casein. (115,439.) Mar. 31.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATIONS ACCEPTED.

18,536 (1919). Norsk Hydro-Elektrisk Kvaelfstof-aktieselskab. Fertilisers containing nitrogen and phosphoric acid. (132,496.) Mar. 24.

24,039 (1919). Barbe. Process for granulating cyanamide. (140,331.) Mar. 31.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Langwell, and Power Gas Corp. Fermentation of cellulose. 8115. Mar. 18.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Baker and Sons, Head, and Prescott. Treatment of food products etc. 7950. Mar. 17.

Becton, and Trufood, Ltd. 9044. *See* I.

Horlick. Food compound. 8310. Mar. 20. (U.S., 22,118.)

Marris, Ross, and Walker and Sons. Preserving animal and vegetable matter. 8860. Mar. 26.

Sherman. Preserving meat. 7960. Mar. 17.

Wood. Food compositions. 8229 and 8230. Mar. 19. (U.S., 19,319.)

COMPLETE SPECIFICATIONS ACCEPTED.

1083 (1919). Wanquier et Cie. Desiccation of potatoes and other vegetable substances. (122,422.) Mar. 31.

5028 (1919). Whyte and Fothergill. Apparatus for treating sewage and other effluents. (140,189.) Mar. 31.

6142 (1919). Naaml. Vennoots, Jurgens' Vereen. Fabr. *See* XII.

17,070 (1919). Chalas. Dry and soluble extract of raw meat. (129,639.) Mar. 31.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Bielouss. Treatment of aromatic materials. 8804. Mar. 25.

Commercial Research Co. Side-chain oxidation. 8208. Mar. 19. (U.S., 7,419.)

Imray (Monsanto Chemical Works). Production of saccharin. 8470. Mar. 22.

Lombaers. Extraction of caffeine from coffee beans. 8276. Mar. 19. (Holland, 13,619.)

21,360 (1919). Morris and Co., and Morris. *See* III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

Elliott. Photography. 8176. Mar. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

4390 (1919). Smith. Screen plates and films for colour photography. (139,871.) Mar. 24.

28,247 (1919). Finnegan and Rodgers. Producing coloured photographs or cinematograph films. (140,349.) Mar. 31.

XXII.—EXPLOSIVES; MATCHES.

COMPLETE SPECIFICATION ACCEPTED.

26,827 (1919). Mellgren. Manufacture of igniting composition for matches. (140,026.) Mar. 24.

XXIII.—ANALYSIS.

COMPLETE SPECIFICATION ACCEPTED.

3171 (1919). Johnson and Brearley. Apparatus for testing the hardness of materials. (140,165.) Mar. 31.

I.—GENERAL; PLANT; MACHINERY.

Distillation and rectification. L. Gay. Chim. et Ind., 1920, 3, 157—166.

In a continuous column the part below the inlet for the liquid to be rectified serves for the volatilisation, and the part above for the rectification of the liquid. According to one method of working, in which each section of the lower part receives a supply of heat and the upper part is cooled throughout its entire length, the contact between the liquid and the vapour phases is reduced to a minimum. In the other method the whole of the heat is supplied to the lowest section, which is often a boiler, and the cooling is confined to the reflux condenser mounted on the top of the column; in this method the contact between the phases is at a maximum. It is shown that the second method is the more efficient, and a number of formulæ, tables, and curves are given from which it is deduced that in the second method the number of sections required in the lower or vaporising portion of the column is governed by the composition of the liquid to be rectified and is practically independent of the amount of heat supplied, whereas in the upper or rectification portion of the column the number of sections necessary does depend upon the amount of heat supplied to the bottom section, but has a minimum value which depends on the desired composition of the condensed liquid to be collected.

—W. H. C.

PATENTS.

Evaporation of water from aqueous liquids. A.-G. Kummel & Matter, Aarau, Switzerland. Eng. Pat. 123,716, 24.10.18. (Appl. 17,387/18.) Int. Conv., 26.2.18.

In the process in which the vapour given off from a liquid on evaporation is heated by compression and used to evaporate more of the same liquid, part of the compressed vapour is blown into the liquid by one or more open steam jets, while part passes through a coil or other known type of heat transmitter.—B. M. V.

Separating; Method of and apparatus for — or separating and recovering (and if desired washing) oil, grease, fat, or fatty matter or the like or other material from water or other liquids or for the separation of two liquids of different densities. L. Linden, London. Eng. Pat. 138,655, 19.7.18. (Appl. 7430/18.)

A SEPARATING chamber is divided into three compartments transversely to the direction of the flow of liquid. The first and third compartments are narrow and are formed by downward projections from the roof. The liquid enters at the liquid level at one end of the chamber, passes down the first compartment to the lower part of the chamber, and then horizontally across the chamber to the third compartment, where it passes upwards to the outlet at the same level as the inlet. Transverse baffle plates of short height prevent disturbance of the liquid in the middle compartment, whilst permitting light material to rise to the surface. This material is withdrawn through a pipe at the liquid level or an opening in the roof by raising the head of liquid. Fatty material may be first melted and washed by the injection of steam through pipes below the floating material. Below the level of the horizontal current of liquid are placed transverse baffle plates of short height for directing the heavy material, falling out from the current, into pockets formed in the bottom of the chamber. These pockets have exit valves below, and are provided with perforated pipes for the treatment of the deposited sludge before removal if desired.—J. H. J.

Mixing machines. J. R. Webb, Wolverhampton, and Ransome & Sons Machinery Co., Ltd., London. Eng. Pat. 139,018, 11.3.19. (Appl. 6096/19.)

A SHAFT revolves in a trough-like vessel and carries a number of discs or wheel-like mixing members inclined to the shaft and to each other. The trough-like container need have only one aperture for filling and emptying, being rotated through about 180° for the latter purpose.—B. M. V.

Condensing apparatus for refrigerating machines. L. Chew and W. F. Jennings, London. Eng. Pat. 139,361, 14.5.19. (Appl. 12,131/19.)

ONE or more vertical series of horizontal tubes is divided into groups by headers at the ends of the tubes, the groups decreasing in number (or size) of tubes from the bottom upwards, so that the velocity of the vapour, which passes upwards inside the tubes in zig-zag fashion and decreases in volume because of condensation, may remain constant. The tubes are cooled by a water spray outside, and their ends are reduced in diameter so that they may be fastened (e.g., by welding) into the headers and yet lie very close to each other in order to maintain a uniform film of cooling water. The interiors of the headers are provided with baffles sloping downwards to effect separation of the liquid and vapour.—B. M. V.

Drying cylinders; Steam inlet and water outlet of —. J. O. Lundberg, Borge, Norway. U.S. Pat. 1,331,994, 24.2.20. Appl., 24.6.19.

THE hollow trunnion of a drying cylinder is provided with a removable cap which does not rotate with the cylinder; the cap carries a steam inlet pipe, a water outlet pipe extending into and bending down to near the lowest point of the cylinder, and a window to permit observation of the water tube.—B. M. V.

Dryer. R. C. Newhouse, Wauwatosa, Assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,332,137, 24.2.20. Appl., 26.6.18.

A CYLINDRICAL casing contains a number of tubes extending the length of the casing. The tubes have a segmental cross-section, and are so arranged that an annular chamber is formed between the casing and the tubes, and radial spaces separate the individual tubes. The annular chamber and the radial spaces are all in communication with one another.—L. A. C.

Dry-kiln. O. W. Degen, Alameda, and W. Degen, San Francisco, Cal. U.S. Pat. 1,332,164, 24.2.20. Appl., 9.8.18.

A CHAMBER containing the goods to be dried is connected with a furnace by a duct; the furnace is provided with a chimney and also with a sheet metal air-pipe leading from the outer air across the fire to a point in the duct leading to the dryer, so that clean warm air is drawn into the dryer. Dampers are arranged so that the products of combustion can be sent, as desired, up the chimney or into the dryer along with the clean air.—B. M. V.

Filter [; Ultra —]. J. F. Wait, Niagara Falls, - N.Y. U.S. Pat. 1,331,732, 24.2.20. Appl., 30.8.17.

AN ultra-filter is constructed of a colloidal membrane supported by a closely woven wire fabric with a smooth surface next the membrane. The wire fabric is backed by a plate with grooves for leading away the filtrate. The whole is fixed in an apparatus adapted to withstand high pressures, with charging and pressure connections on one side of the filter and discharge and negative pressure connections on the other side.—J. H. J.

Separator; Revolving ——. A. B. Carstens, Monterey, Mexico, Assignor to The American Metal Co., Ltd., New York. U.S. Pat. 1,331,802, 24.2.20. Appl., 1.10.18.

A SEPARATOR for molten materials of differing specific gravity consists of a rotary cylindrical vessel provided with two sets of tap holes diametrically opposed in the ends. The axis of the cylinder is slightly inclined to the horizontal, and axially disposed openings in the ends serve for the admission of material and heat to the interior.—T. St.

Heating or cooling apparatus. R. Achard, Lyon, France. U.S. Pat. 1,332,992, 24.2.20. Appl., 26.12.17.

A NUMBER of short doubled-walled tubes (the spaces between the two walls being narrow) are arranged horizontally in groups, with vertical pipes connecting alternate ends of the tubes. The liquid to be heated or cooled is passed through the vertical pipes and the short tubes, and the heating or cooling medium through the jackets of the double-walled tubes.—B. M. V.

Atomising liquids for purposes of drying, concentration, mixing, or reaction; Apparatus for ——. L. Galland, Berlin-Wilmersdorf. Ger. Pat. 307,152, 21.10.17.

Rows of jets are grouped in one or more clusters in an atomising or drying chamber. Each row or cluster has its own separate supply of compressed air and liquid. Drying of the atomised liquid is effected more quickly than is possible by the use of long atomising tubes passing through the chamber.—J. S. G. T.

Kilns for burning cement, lime, dolomite, etc.; Compressed air inlet for ——. Amme, Giesecke und Konegen A.-G., Brunswick. Ger. Pat. 315,775, 11.5.18.

THE mouth of the inlet is divided into channels by a grating composed of rods of rhombic cross-section, each of which can be separated into two parts of triangular cross-section. The inner side of the grating, which is the more liable to damage by heat and mechanical wear, is therefore easily replaced, whilst the sound rear portion can be retained; the device also facilitates the clearing of the narrowest parts of the air channels if these become choked.—D. F. T.

Cooling chambers. Eng. Pat. 139,383. SEE XIXA.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coking plants; Standardisation of ——. O. M. Schadeck. Stahl u. Eisen, 1919, 39, 1349—1350.

THE necessity of standardisation of existing coking plants is discussed. No actual standards are suggested, but the author recommends the standardisation of pipes, dampers, arches, and the like, and the construction of standard units in new plants.—A. G.

Coal gas; Composition of the unsaturated hydrocarbons present in ——. F. S. Sinnatt and L. Slater. Analyst, 1920, 45, 85—87.

COAL gas was passed at the rate of 10 litres per hr. through wash-bottles containing bromine; at the end of the absorption period the liquid in the bottles was washed with dilute sodium hydroxide solution, then with water, and dried over anhydrous potassium carbonate. Two experiments were made, 700 litres of gas being used in the first and 1500 litres in the second, the weights of liquid bromides obtained being 235 and 520 grms. respectively. The liquid was distilled under 15 mm. pressure, the fractions boiling below 100° C. and between 100° C. and 145° C. being collected separately. The fraction boiling below 100° (15 mm.) was then fractionally distilled. From the results of the two experiments it is calculated that the composition of the unsaturated hydrocarbons was respectively ethylene, 83.8, 84.3; propylene, 13.4, 11.8; butylene, 1.7, 2.3; and amylene, 1.0, 1.5% by vol. The gas contained 3.5—4.5% of unsaturated hydrocarbons.—W. P. S.

[Gas] purification; Oxide ——. G. W. Anderson. Gas J., 1920, 149, 688—690.

THE best working results are obtained when 3—4 cb. ft. of oxide is provided for every 100,000 cb. ft. of gas per annum. Figures are quoted from working results of a number of plants running on gas containing 1.0—1.2% H₂S and 2% of air. Four purifier boxes were connected in series, the first one being disconnected and recharged as soon as any H₂S was detected at the outlet of the third box. The oxygen-content of the purified gas should not be higher than 0.2—0.3% and the temperature should not exceed 26°—30° C., the inlet temperature being 20° C.; 0.25% of steam per 1000 cb. ft. of gas may be admitted to keep the oxide moist. A mixture of "Lux" oxide with 30%—40% by volume of bog-ore is recommended. Such a mixture, operating under the conditions mentioned, can be discarded after once or twice revivifying. The same effect is obtained by the rotation system, which has been successful chiefly in plants where the quantity of available oxide in the purifiers was small in proportion to the amount of gas produced. The size of the purifying plant has an important bearing on its efficiency, and the design of the plant should proceed on the following lines:—If the gas velocity be 0.2 in. per sec., the section of each box should be 0.7 sq. ft. per 1000 cb. ft. output in 24 hours. If the total depth of oxide in each box exceeds 24—30 in., a divided flow of gas should be resorted to. For regeneration of the oxide outside the purifiers 0.67—0.87 sq. ft. of surface area is required per 1 cb. ft. of oxide in the purifiers. An estimate of the plant necessary to deal with a yearly output of 450 million cb. ft. of gas is given.—A. G.

Benzene [petrol] from lignite tar; Production of — by cracking. F. Fischer and W. Schneider. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 122—149. Chem. Zentr., 1919, 90, IV., 1074—1075. (See this J., 1919, 672 A.)

BENZENE has been obtained hitherto from lignite

tar either by heating under pressure or by superheating at normal pressure; the behaviour of the tar when heated to the boiling point for a long time has now been examined. The fractions of tar from Riebeck's montan works which boil above 275° C. were partially decomposed when heated at 300°–315° C. for 13 hours. The specific gravity fell, and 20% distilled below 200° C., 73% below 250° C., and 88% below 275° C. Protracted heating of the tar fraction at 350°–500° C. lowered the specific gravity of the decomposition distillate to 0.81–0.83, and a yield of 66.9% was obtained, which fell to 63% after an acid-alkali wash. The products boiling below 300° C. may be regarded as newly formed and amount to 46.8%. The distillate has the composition:—B. pt. 60°–100° C., 4.2% (sp. gr. 0.681 at 20° C.); 100°–150°, 6.9% (0.743); 150°–200°, 11.3% (0.7799); 200°–250°, 19.7% (0.8198); 250°–300° C., 32.4% (sp. gr. 0.8502 at 20° C.). The yield of products boiling below 150° C. was less than is obtained by the other methods previously used. The products obtained by the different methods are compared in the following table:—

Lignite tar cracked by	Specific gravity of fraction.		Bromine number.	
	below 100° C.	100°–150° C.	below 100° C.	100°–150° C.
1. Heating under pressure ..	0.667	0.758	69	58
2. Slow heating .	0.681	0.743	112	98
3. Superheating at ordinary pressure ..	0.715	0.818	150	97

The products under Series 3 were treated with zinc chloride, which reduced the bromine number more than the alkali-acid wash. The yield of unsaturated compounds is much less where heating under pressure is used, probably because the compounds being retained for a time in an autoclave become polymerised. Experiments were made to see if polymerisation occurred in the protracted distillation as here practised. The tar was distilled and paraffin crystallised out at 5° C. After removing fractions boiling below 250° the tar was heated to 280°–330° C. The specific gravity of the distillate (0.88–0.89) indicated little decomposition. A further heating for 64 hours at 335°–350° C. gave after the acid and alkali wash 6.7% of a light oil up to 150° C., indicating considerable decomposition. The residue was a semi-solid mass (13.9%) from which a lubricating oil could be obtained with viscosity at 20° C., 35.5° (Engler), flash point 108°, sp. gr. at 20°, 0.992, setting point 11° (without stirring). The corresponding fraction from a tar rapidly distilled *in vacuo* had a viscosity at 20°, 19.2° (Engler), setting point 15° (without stirring), flash point 197°, sp. gr. at 20°, 0.965. The protracted distillation had led to a certain thickening of the oil. The disadvantages of the lignite benzines are the pungent smell and high percentage of unsaturated compounds. Decomposition under pressure reduces the latter, as also does washing and hydrogenation. In the future it is possible that these products will form the raw material for chemical manufactures.—H. J. H.

[Petroleum] oil-field emulsions. J. L. Sherrick. J. Ind. Eng. Chem., 1920, 12, 133–139.

To be accepted by transporting companies in the United States crude petroleum must not contain more than 2% of water, and this necessitates treatment of emulsions in the field. The emulsions in Goose Creek (Texas) oil-fields consist of salt solution and oil containing asphalt, and experimental

results obtained with them are applicable to the products of that district in general. When subjected to an electrical current the water particles migrated to the anode. The negative charge on the water particles could be neutralised and the water precipitated by the addition of cations which were strongly adsorbed, such as ferric ion. The results obtained with ferric chloride and ferric nitrate showed that both ions of an added electrolyte are effective in precipitating the charged particles. The effect of ether in reducing the stability of such emulsions is probably due to its solvent action upon the asphalt, rather than to any increase in the density of the two liquid phases. A mixture of ether and carbon bisulphide of the same sp. gr. as the emulsion will also cause water to separate. It is probable that the action of certain commercial preparations used for treating emulsions is due to their being hydrophilic colloids.

—C. A. M.

Paraffin was (pentacontane $C_{50}H_{102}$) found in Lancashire coal; Solid —. F. S. Sinnatt and M. Barash. Inst. Min. Eng., Nov. 11, 1919.

A DEPOSIT of several tons weight was found over 30 years ago in the Arley mine at a depth of 440 yards. This consisted of a dark brown, brittle, tasteless, and odourless wax. It contains no sulphur, nitrogen, ash, or halogens, and is practically insoluble in all solvents in the cold, but dissolves in hot benzene, toluene, chloroform, carbon tetrachloride, and aniline. The wax is unaffected by strong alkalis and acids, except by hot concentrated sulphuric acid. Hot liquid bromine has no action on the wax. On bleaching a hot benzene solution with animal charcoal, a white amorphous solid was produced, m. pt. 93.0° and solidified at 92.7° C. Under 15 mm. pressure the wax boiled at 420°–422° C., and about 85% distilled without decomposition. The sp. gr. is 0.9422 when cold and 0.7940 at the melting point. The substance has the formula $C_{50}H_{102}$, and is the highest homologue of the paraffin series so far discovered occurring naturally.

Fuel; Artificial —. L. Lane, Loughor, and D. H. Williams, Grovesend, S. Wales. Eng. Pat. 139,094, 2.7.19. (Appl. 16,523/19.)

THE fuel consists of a mixture of anthracite duff, waste pitch, sodium nitrate, carbonaceous shale, and/or "clod," with or without a small quantity of dried clay. The waste pitch is a grease produced in the lubrication of rolls or similar machinery or in the manufacture of tin-plate. "Clod" is mineralised mud mixed with carbonaceous clay. The coal is heated and mixed with the nitre before adding the waste pitch, and the mixture is briquetted and left to harden for 24 hours.—A. G.

Coal; Agglutinant for the conglomeration of —. L. A. E. Irazusta, Zarauz, Spain. Eng. Pat. 139,106, 7.8.19. (Appl. 19,477/19.)

COAL is briquetted with the aid of 3–4% of an agglutinant composed of 3% of tallow or other greasy substance and 97% of tar.—A. G.

Fuel; Artificial —. B. G. Seccombe and J. Sandiford, Manchester. Eng. Pat. 139,115, 25.8.19. (Appl. 20,800/19.)

COAL slack is briquetted with clay, lime, fibrous material, salt, nitre, alum, and sulphur.—A. G.

Pulverulent fuel installations for use in connection with furnaces. Quigley Furnace Specialties Co., Inc., New York. Eng. Pat. 126,638, 7.5.19. (Appl. 11,386/19.) Int. Conv., 8.5.18.

CRUSHED coal freed from iron by means of a magnetic separator is dried in a rotary dryer and conveyed to storage-bins which feed the pulverisers. A suction fan conveys air and pulverised coal from the pulveriser to a cyclone-separator from which the main body of air returns to the pulveriser and is used over and over again. The coal dust is delivered to a storage-bin with a gate discharge, through which it falls into a blowing tank comprising a large upright cylinder set upon the platform of a weighing-machine of the "quick reading, net" type. From the tank onward a compressed-air system of transportation for the pulverised coal is employed. The outflow of fuel from the tank is controlled by internal mechanism operated by a bell-crank and lever which can be locked in any desired position by a quadrant and latch device. The flow of fuel to any particular furnace on the distribution main can be regulated by the weight of fuel sent from the blowing tank. Accumulations of pulverised coal in the main can be cleared by means of an auxiliary compressed air line. The fuel is injected into the furnace by means of a jet, secondary air being supplied for combustion by means of a concentric pipe. The advantages of this system are that only such quantity of coal is pulverised as is needed for immediate use, and the powdered coal being kept in air-tight storage bins, oxidation is retarded, and hence spontaneous combustion is not likely to occur.—A. G.

Storage of acetylene or other gas; Fillings for tanks or the like intended for the —. A. U. Särnmark, Göteborg, Sweden. Eng. Pat. 123,534, 17.2.19. (Appl. 3927/19.)

THE filling material is composed of ceramic or other porous material reinforced by loose strands of metal wire, such as iron, of short length evenly distributed throughout the mass. To prevent entanglement the strands are straight or only slightly bent. The reinforced mass may be made into briquettes or slabs, which are inserted in the tanks. (Reference is directed to Eng. Pat. 23,856 of 1910; this J., 1911, 349.)—J. S. G. T.

Liquid hydrocarbons; Refining —. A. E. Dunstan, Sunbury-on-Thames. Eng. Pat. 139,233, 3.6.18. (Appl. 9114/18.)

OXIDISABLE sulphur compounds present in mineral oils are removed by the action of an alkaline solution of a hypochlorite, such as sodium hypochlorite.—A. E. D.

Motor fuel for internal combustion engines. G. F. Dinsmore, Boston, Mass. U.S. Pat. 1,331,054, 17.2.20. Appl., 19.3.19.

CRUDE wood naphtha is mixed with petroleum distillate (kerosene). The acetone is dissolved by the kerosene, and the solution is separated from the undissolved methyl alcohol.—A. E. D.

Oil-cracking still. J. L. Gray, St. Louis, Mo. U.S. Pat. 1,331,909, 24.2.20. Appl., 21.2.17. Renewed 13.11.19.

OIL is superheated in a cast-iron cylindrical casing containing straight lengths of wrought-iron pipe arranged parallel to the axis of the cylinder and embedded in its wall. These pipes are connected by means of return bends, so as to form continuous

conduits passing from side to side from the lower to the upper part of the casing.—C. A. M.

Liquid fuel; Production of —. Konsortium für Elektrochem. Industrie G.m.b.H., Munich. Ger. Pat. 315,290, 30.8.17.

ACETALDEHYDE and paraldehyde are mixed in proportion adjusted to give the desired volatility. The mixture, which burns with a non-luminous and non-smoky flame, has approximately the same calorific value as methylated spirit.—H. J. H.

Lubricating oil [from mineral oils]; Process for obtaining — by means of sulphurous acid. Allgem. Ges. für chem. Industrie m.b.H., Berlin. Ger. Pat. 315,289, 20.7.17.

THE portion soluble in liquid sulphur dioxide which is extracted from suitable hydrocarbon oils is treated with dry ammonia gas, and the ammonium salts thus formed are removed. The excess of ammonia is expelled by passing air through the heated oil. The product contains an extremely small quantity of ammonium sulphite and ammonium sulphate, which remains dissolved in the oil or finely suspended. The lubricating oil produced has a high viscosity and a very low solidifying point.—J. F. B.

Aluminium chloride residues [from treatment of mineral oils]; Utilisation of —. L. S. Abbott, Port Arthur, Tex., Assignor to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,332,018, 24.2.20. Appl., 1.7.19.

PART of the carbon in the residues is burned to heat the remaining carbon to incandescence, and a current of heated chlorine is then passed through the incandescent mass.—W. J. W.

Lubricating oil purifying and reclaiming systems. The De Laval Separator Co., New York, Assignees of F. W. Kennedy, Trenton, N.J., U.S.A. Eng. Pat. 134,196, 13.8.19. (Appl. 19,904/19.) Int. Conv., 23.10.18.

Combustion products; Apparatus for generating — under pressure. C. M. Pattison, Pentre, Wales. U.S. Pat. 1,331,523, 24.2.20. Appl., 27.11.18.

SEE Eng. Pat. 129,725 of 1917; this J., 1919, 673 A.

Hydrocarbons; Treatment of liquid — for the transformation thereof. N. C. and C. E. Cassal and B. H. Gerrans, London. U.S. Pat. 1,330,844, 17.2.20. Appl., 12.9.17.

SEE Eng. Pat. 117,087 of 1916; this J., 1918, 501 A.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Defecation sludge obtained in the manufacture of sugar; Production of terpenes and other products by dry distillation of —. H. Stoltzenberg, Berlin-Wilmersdorf. Ger. Pat. 316,503, 8.8.17.

To prevent decomposition the sludge is dried immediately it is produced without the addition of any other substances, and the dried product is distilled. The oily and aqueous fractions of the distillate are worked up separately to resin substitutes, pyridine bases, acetone, and Pyrrole Red. An alternative method is to separate the sludge into three fractions by precipitation and treat these separately: a resinous fraction yielding a high percentage of terpenes and resin; a fraction with a high nitrogen content yielding mainly bases; and a fraction rich in fatty acids yielding principally acetone.—L. A. C.

Electric incandescent lamps. Siemens und Halske A.-G., Siemensstadt, Germany. Eng. Pat. 112,264, 22.11.17. (Appl. 17,211/17.) Int. Conv., 29.12.16.

In electric incandescence lamps, more particularly those known as gas-filled carbon lamps, rare gases specially purified to remove the last traces of nitrogen are used as the lamp-filling medium. The life of the filament is much increased thereby and its load capacity considerably augmented.—J. S. G. T.

Leading-in conductor [e.g., for electric lamps]. J. H. Anderson, Cleveland, Ohio, Assignor to General Electric Co. U.S. Pat. 1,331,085, 17.2.20. Appl., 28.8.15.

THE conductors are composed of a metal having a higher coefficient of expansion than the vitreous material into which they are sealed, and they are provided with one or more thin radial flanges at the sealing point.—B. V. S.

Vacuum tubes; Production of electropositive electrodes in —. W. Kossel, Munich. Ger. Pat. 307,674, 26.1.18.

A LESS electropositive material is converted into a more electropositive substance *in vacuo* in the absence of oxygen. As an example, amalgams are in general more electropositive than the corresponding metals, e.g., zinc.—J. S. G. T.

Discharge tubes; Incandescence cathode for —. F. Skaupy, Berlin. Ger. Pat. 310,712, 16.6.18.

In cathodes of the Wehnelt type the support for the material affording emission of electrons is composed of osmium. The range of possible substances which may be employed as sources of electronic emission is thereby extended on account of the higher temperature at which osmium may be used compared with platinum and iridium.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Lignite tar; Action of concentrated and fuming sulphuric acid on the fraction 200°–300° C. of —. W. Schneider and O. Jantsch. Ges. Abhandl. Kenntn. Kohle, 1918, 3, 191–99. Chem. Zentr., 1919, 90, IV., 1073.

THE fraction 200°–300° C. of a tar from the Riebeck Montan works freed from phenols and bases was shaken repeatedly with concentrated sulphuric acid and 59.4% was dissolved. The process was continued with fuming acid containing respectively 9% SO₃ and 15% SO₃, when a further 29.2% of the oil dissolved, leaving 11.2% of a colourless oil, 90% of which distilled between 200° and 300° C. and had sp. gr. 0.772 at 20° C. The residue solidified on cooling. The same fraction of a low temperature coal tar treated similarly left almost the same percentage of residue insoluble in acid, but a larger proportion dissolved in the concentrated acid. It is concluded that the proportion of paraffin is approximately the same in the fraction of both tars, whereas the lignite tar fraction contains the smaller proportion of unsaturated hydrocarbons (soluble in strong sulphuric acid) and a larger proportion of aromatic and hydroaromatic hydrocarbons (soluble in fuming sulphuric acid). 500 c.c. of a lignite distillation tar fraction (200°–300° C.) washed free of phenols and bases was treated once with 550 c.c. of concentrated sulphuric acid, leaving 48% undissolved. The acid tar treated with water gave 18.2% of neutral oil and 21% of oily sulphonic acid. The neutral oil was a moderately viscous lubricant, 40% of which distilled over up to 287° C. when decomposition set in.—H. J. H.

Catechol. B. Elsner. Monatsh., 1919, 40, 361–362.

AT dilutions not greater than 1%, with excess of cold barium hydroxide solution, catechol gives a precipitate of a very sparingly soluble barium salt, C₆H₂O₂.Ba₃11₂O, in the form of silver-grey leaflets with a pearly lustre. Since resorcinol and quinol give no such precipitate, the reaction is suggested as a means of separation, which is probably superior to that of depending upon the use of benzene.

—J. K.

PATENTS.

Sulphonation, nitration, and chlorination of aromatic substances; Apparatus applicable for the —. H. N. Morris and Co., and H. N. Morris, Manchester. Eng. Pat. 139,234, 5.6.18. (Appl. 9256/18.)

THE apparatus consists of a number of reaction chambers each divided into two compartments, one above the other, with communicating passages and condensing chambers above; the upper compartment of each reaction chamber is fitted with two or more atomisers through which the reacting substances are introduced and the lower compartment with coils for the control of the temperature.

—D. F. T.

Carbazole; Purification of —. South Metropolitan Gas Co., and W. Kirby, London. Eng. Pat. 139,441, 11.11.19. (Appl. 28,279/19.)

THE precipitate produced by the addition of water to a solution of carbazole in concentrated sulphuric acid is obtained in comparatively large crystals which can easily be removed by filtration if the dilution is effected by exposure to a moist atmosphere.—D. F. T.

Side-chain oxidation. [Preparation of benzoic acid from toluene.] V. Coblenz and H. W. Walker, Assignors to Commercial Research Co., New York. U.S. Pat. 1,332,028, 24.2.20. Appl., 7.4.19.

BENZOIC acid is manufactured from toluene by "stratifying" this with nitric acid of 20–43% concentration at a temperature somewhat below the boiling point of the toluene, the materials being left in contact until reaction is complete and escaping vapours condensed and returned to the reaction mixture.—D. F. T.

Retene and its derivatives; Preparation of aromatic nitro-compounds from —. R. Arnot, Zürich. Ger. Pat. 315,623, 2.8.18.

RETENE, retenequinone, or high-boiling resin oil (tar tallow) is treated with nitric acid of sp. gr. greater than 1.43 in the presence or absence of fuming sulphuric acid. *Examples.*—Dinitroretene, prepared by the action of nitric acid of sp. gr. 1.48 to 1.52 at 15° C. on retene or tar tallow, is a flocculent yellow compound soluble with difficulty in aqueous alkalis, and soluble in most organic solvents; on reduction it forms an amine which can be diazotised and coupled with the usual components. Nitroretene-sulphonic acid, a yellowish-brown compound, is prepared by the action of nitric acid and 20% oleum on retene.—L. A. C.

Naphthalene and other crystalline substances which can be sublimed; Purification of —. Mitteldutsche Teerprodukten- und Dachpappenfabr. P. Riehm, Grifte. Ger. Pat. 315,958, 6.3.18.

NAPHTHALENE, phthalic anhydride, camphor, indigo, arsenious acid, cinnabar, ammonium chloride, or the like, is purified by fractional sublimation in an apparatus consisting of an inner chamber into which the vapour is first led, one or more outer chambers surrounding the inner chamber on all sides, and a final cooling chamber. In the case of naphthalene, large crystals of a high degree of purity are de-

posited in the inner chamber; the product in the outer chambers is somewhat less pure, while the last fraction deposited in the final chamber is of an oily nature.—L. A. C.

Coumarone resin. Ger. Pat. 302,543. See XIII.

IV.—COLOURING MATTERS AND DYES.

Azo-derivatives of indoxyl. J. Martinet and O. Dornier. Comptes rend., 1920, 170, 592—594.

WHEN the requisite amount of a diazo compound is added to a mixture of ice and an indoxyl melt neutralised by sulphuric acid, azo-derivatives of indoxyl are readily obtained. The authors have, in this way, prepared 2-methyl-, 3-methyl-, 4-methyl-, 2,4-dimethyl- and 2,3,5-trimethylbenzeneazindoxyls and α - and β -naphthaleneazindoxyls. All of these compounds decompose on melting. (See further J. Chem. Soc., 1920, i., 335.)—W. G.

[*Light*] filters. Miethe and Stenger. See XXI.

PATENT.

Purifying substances by sublimation. Ger. Pat. 315,958. See III.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Textiles; Testing the mildew resistance of —. B. S. Levine and F. P. Veitch. J. Ind. Eng. Chem., 1920, 12, 139—141.

IN testing the resistance offered by fabrics to mildew the incubation period should not be less than 30 days under aerobic conditions of growth in subdued light, and at a suitable humidity and temperature. Six discs about 1½ in. in diameter are cut from the fabric to be tested and immersed in running (or frequently changed) water for at least 2 days to remove water-soluble fermentable or fungicidal substances. They are then pressed between absorbent paper and placed in six bacteriological Petri plates containing 10 to 15 c.c. of agar jelly free from nutrient substances. The plates, which must not be air-tight, are incubated for 7 to 10 days in a closed chamber at 20°—25° C. If a well-developed growth has appeared the test is discontinued. Otherwise the discs are inoculated with stock cultures of *Alternaria*, *Cladosporium* and a pink *Mucor*, and the incubation renewed for 3 to 4 weeks. After this period the amount, nature, and extent of the growth, and the amount of discoloration and the strength of the fabric are noted, and the sample classified in accordance with an arbitrary scale in which 0 represents susceptibility to mildew with tendering of the cloth, and 10 "mildew-proof," with no growth of mould and no discoloration of the cloth. Laboratory results thus obtained agreed fairly well with the results of practical tests in which pieces of treated and untreated cloth were stretched in the form of tents and exposed to weather conditions for upwards of a year.—C. A. M.

Flax and hemp fibres; Differentiation of —. R. Haller. Neue Faserstoffe, 1919, 1, 229—230. Chem. Zentr., 1920, 91, II., 48.

THE fibres of flax and hemp show quite different swelling phenomena on treatment with concentrated caustic soda. Flax swells uniformly, and the contents of the central canal show up distinctly, whilst the fibre substance becomes uniformly transparent. In the case of hemp the contours become irregular, the fibre remains non-transparent, and the wall of the central canal does not stand out

distinctly. The diameter of the flax fibre increases on an average by about 83%, and that of the hemp fibre by only 25%. The flax fibre in contact with the alkali makes likely worm-like contortions; the hemp fibre also bends about but less vigorously. On treatment with cuprammonium reagent the flax does not show barrel-shaped swellings, but the hemp fibre does. If the fibres are dyed with a strong solution of Dianil Blue PH in concentrated caustic potash lye and examined under the microscope, the flax shows knotty swellings and cross lines at irregular intervals which are more deeply dyed; in the case of hemp there are numerous cross lines, but these are not appreciably darker in colour than the rest of the fibre.—J. F. B.

Aeroplanes; Material and dopes for the planes of —. A. Fuchs. Chim. et Ind., 1920, 3, 167—172.

DETAILS are given of the various materials used for planes and of the dopes or varnishes used to render them waterproof. Cellulose acetate and other materials used as bases for the dopes are discussed, as well as the most appropriate solvents. Materials for increasing the plasticity of the film when dry and for reducing its liability to fire, the methods of applying the dopes, of drying the films, and of recovering the vaporised solvents are considered.

—W. H. C.

PATENTS.

Fibrous plants [yucca]; Process of treating — for the recovery of fibres. W. Loehr, Bloomington, Cal. U.S. Pat. 1,330,127, 10.2.20. Appl., 28.5.19.

YUCCA plants are crushed, boiled in an alkaline solution until the cellular tissue is softened, treated with dilute solution of alum, washed in cold water, and the fibre then shaken and dried.—J. F. B.

Vegetable fibres; Process for making — lustrous. P. Kraiss, Dresden, and O. Röhm, Darmstadt. Ger. Pat. 315,398, 24.9.18.

FIBRES in the raw or manufactured form are treated for a long time with a solution of the enzymes of the pancreatic gland at a moderate temperature, then washed and dried. Flax, ramie, and nettle fibres so treated acquire a permanent silky gloss.

—J. F. B.

Papers for use as a dielectric for electrical condensers and other purposes. F. Haigh, Stoke-on-Trent. Eng. Pat. 138,226, 9.4.19. (Appl. 8969/19.)

EXTREMELY thin tissue paper is coated with a homogeneous substance possessing good electrical insulating properties, such as pyroxylin, collodion, nitro-cellulose, or cellulose acetate. The thin paper is supported by a backing of a heavier paper, the two papers being pressed together in a moist condition during manufacture (Eng. Pat. 24,981 of 1911). The coating is then applied to the thin paper while in contact with the support, and the backing is removed before the paper is used.—J. F. B.

Paper, yarns, and fabrics; Process for waterproofing —. H. T. Böhme A.-G., Chemnitz. Ger. Pat. 315,412, 13.12.16.

THE goods are treated with water-soluble oils and sizing agents. Complete waterproofing of paper is effected by precipitating the oil from its aqueous emulsion by means of weak acids or acid salts on the fibre, with the simultaneous use of sizing agents. The oils may be added to the pulp in the hollander.

—J. F. B.

Sponge; Manufacture of an elastic artificial — from plant structures. J. Hach and E. Dreyfuss, Kaiserslautern. Ger. Pat. 315,185, 9.2.18.

THE leaves and stems of various peat mosses, especi-

ally *Sphagnum cymbifolium*, are torn up in a "rag-devil" and treated in the half-dry condition with calcium hydroxide, the excess of which is subsequently neutralised with dilute acetic acid. The cell walls are thereby hardened or "tanned" and permanently preserve their elastic condition. The mass has the properties of a natural sponge.

—J. F. B.

Artificial silk; Apparatus employed in manufacture of —, J. Clayton, Coventry. Eng. Pat. 139,104, 5.8.19. (Appl. 19,297/19.)

Paper making machines; Dryer for —, J. E. Alexander, Port Edwards, Wis. U.S. Pat. 1,390,366, 10.2.20. Appl. 26.11.17.

Drying cylinders; [Doll-head bearings of] textile and like —, E. Farrell, Salford. Eng. Pat. 139,261. (Appls. 1876, 25.1.19, 7073, 21.3.19, and 9681, 16.4.19.)

Impregnating or treating textile fabrics and other materials; Apparatus for —, J. D. Taylor, London. U.S. Pat. 1,331,729, 21.2.20. Appl. 14.11.17.

SEE Eng. Pat. 106,805 of 1917; this J., 1917, 869.

Adhesives. Ger. Pats. 316,080 and 316,234. See XVII.

Saccharification of cellulose. Ger. Pat. 304,400. See XVI.

Saccharification of cellulosic material. Ger. Pat. 304,399. See XIXa.

Product for nitration from wood cellulose and cotton. Ger. Pat. 300,844. See XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Printing white reserves on wool. M. Battagay. Bull. Soc. Ind. Mulhouse, 1919, 85, 103—141.

THE strong reducing properties of wool distinguish it from cotton. Consequently discharges on wool must be brought about by reduction. Theoretical considerations, supported by experiment, indicate the hydrosulphites—especially if they be mixed with a covering material such as zinc oxide and lithopone—to be most suitable. A suitable paste is 200 grms. of sodium tungstate, 200 grms. of thickening (e.g., 1 part of maize starch, 1 of water, 8 of gum tragacanth), 500 grms. of hyalidite, and 20—50 grms. of glycerin. The tungstate is fixed in a bath of a barium salt. The substituted amines, formed by reduction of the dyestuff, unite with the wool and determine the possibility of future discoloration. Naphthylamines substituted in the 1- and 8-positions give bad discolorations. *p*-Phenylene-diamine is inert. In the latter part of the paper the chemical and physical properties of wool are summarised, and its relationship to the proteins is shown.—A. J. H.

Discharges on wool. E. Jaquet. Sealed note 1432, Dec. 12, 1903. Bull. Soc. Ind. Mulhouse, 1919, 85, 142. Report by M. Battagay, *ibid*, 142—143.

A METHOD for obtaining white discharges on wool by means of a mixture of sodium hydrosulphite, albumin, zinc oxide, and gum is described. Battagay reports this discharge to be liable to discoloration (see preceding abstract).—A. J. H.

PATENTS.

Washing textiles. L. Elkan Erben, G.m.b.H., Berlin. Ger. Pat. 315,835, 21.11.17.

AN electric current is passed through a solution of saponin and sodium chloride whilst this is being used for washing textiles.—L. A. C.

Water-glass; Means for preventing the harmful effects of fabrics cleaned with —, W. Reichel, Munich. Ger. Pat. 316,293, 16.1.17.

FABRICS cleaned with water-glass are rinsed afterwards in a dilute solution of ammonium chloride to prevent them from causing irritation on coming in contact with the human skin.—L. A. C.

Colouring product and tinctorial mordant, R. H. and M. H. Vegas, Buenos Aires, Argentina. U.S. Pat. 1,330,992, 17.2.20. Appl. 17.6.18.

SEE Eng. Pat. 129,761 of 1918; this J., 1919, 760 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sodium perborate and perborate soap powders; Determination of available oxygen in —, H. Trickett. Analyst, 1920, 45, 88—91.

THE iodometric method yields the most trustworthy results, but, in the case of soap powders and the like previous removal of the soap is necessary. A method which may be applied directly to perborates and soap powders consists in treating the perborate solution with sodium hypochlorite solution in a nitrometer and measuring the volume of the liberated oxygen. The results obtained agree with those found by the iodometric method. Titration of perborates with permanganate is not very reliable; the best results are obtained by adding a slight excess of the perborate solution to a definite volume of permanganate solution acidified with sulphuric acid, and then titrating the excess with permanganate. The titration should be carried out at 15°—20° C., and the acid concentration should be 5 of sulphuric acid on the total volume. The gasometric determination of perborates by decomposition with permanganate is untrustworthy.

—W. P. S.

"Buffer" system; primary phosphate-bicarbonate-free carbonic acid, in place of the system; primary phosphate-secondary phosphate. W. Windisch and W. Dietrich. Woch. Bran., 1920, 37, 81—83.

THE authors investigated the changes of surface tension of solutions of eucupine dihydrochloride resulting from the liberation of the capillary-active free base (cp. Traube, this J., 1915, 853) under the influence of secondary potassium phosphate before and after treatment of the solutions with carbon dioxide. It is concluded that excess of carbon dioxide effects a practically complete conversion of secondary potassium phosphate into the primary salt and potassium bicarbonate. In living and breathing tissues, and in fermenting liquids, therefore, all the phosphate must be present as primary salt in equilibrium with potassium bicarbonate and free carbon dioxide. Primary and secondary phosphates can only coexist after production of carbon dioxide by respiration or fermentation has ceased.

—J. H. L.

Water-glass; Colloidal method for increasing the volume of adhesive —, J. D. Macdonald. J. Ind. Eng. Chem., 1920, 12, 174—176.

ON adding an electrolyte to water-glass the colloidal silica is coagulated, but if the solution is stirred during the addition, and for some time afterwards,

the gel particles cannot coalesce, but are redissolved, i.e., "peptised." By adding brine about two-thirds saturated in a thin stream to the water-glass whilst this is mechanically stirred it is possible to increase the volume of the water-glass solution up to about 25% without impairing the viscosity or adhesive properties of the liquid, which will contain from 3 to 4% of sodium chloride. The final viscosity of the solution may be varied to a considerable extent by small changes in the concentration of the brine. The treated adhesive does not deteriorate when kept out of contact with the air.

—C. A. M.

Lead chloride; Vapour pressure of —. E. D. Eastman and L. H. Duschak. U.S. Bureau of Mines, Tech. Paper 225, June, 1919. 14 pages.

In connection with the treatment of ores by a process involving a chloridising roast and volatilisation of the chlorides of the metallic constituents, the vapour pressure of lead chloride was determined. The method employed was a determination of the weight of substance required to saturate a quantity of inert gas at constant temperatures and pressures. The vapour pressures for temperatures between 500° and 850° C. are given and are shown on a graph, as well as those for solid lead chloride down to 400° C. Values for the vapour pressure estimated from the "smoothed" graph are: 400°, 0.00174; 500°, 0.141; 600°, 2.82; 700°, 22.4; 800°, 116; 900°, 433 mm. of mercury at 0° C. The melting point was determined as 495° C., and the boiling point as 945° C. at 754 mm. The heat of vaporisation at the melting point was calculated to be 40,600 cal.

—W. J. W.

Marine algæ as foods. Gloess. See XIXa.

Titration of mixed acids. Kolthoff. See XXIII.

Halogens. Lamb and others. See XXIII.

Ammonium molybdate. Neubauer and Wolferts. See XXIII.

PATENTS.

Nitric acid; Manufacture of highly concentrated — from dilute nitric acid. A. Clemm, Mannheim. Ger. Pats. (A) 303,313 and (B) 304,233, 2.12.16.

(A) DILUTE nitric acid is converted into barium nitrate by the addition of barium sulphide. The barium nitrate is freed from water and heated with concentrated sulphuric acid, and the residual barium sulphate is reduced. Strontium sulphide may be employed instead of barium sulphide. (B) The dried barium nitrate is treated with an excess of concentrated sulphuric acid at the ordinary temperature, and the mixed acid obtained, which is of such a concentration that it may safely be transported in iron vessels, is separated from barium sulphate by decantation or filtration in a closed heated filter. Residual nitric acid is removed from the barium sulphate by washing with concentrated sulphuric acid, and the sulphuric acid remaining in contact with the barium sulphate is utilised by adding the requisite amount of barium nitrate and heating the mixture, as described in the previous patent.—L. A. C.

Nitric acid; Concentration of aqueous —. H. Pauling, Berlin-Lichterfelde. Ger. Pat. 305,553, 31.5.17.

THE aqueous nitric acid and the dehydrating agent with which it is mixed, e.g., sulphuric acid, are heated, before or after mixing, and the heated mixture is submitted to the action of a current of dry air or other inert gas, also heated if necessary;

the evolved nitric acid vapours may be further treated with sulphuric acid. A similar process can also be applied to the dehydration of other substances, such as alcohol and acetic acid.—D. F. T.

Nitrogen oxides; Process for recovery of —. *Process for recovery of nitrous oxides.* P. A. Guye, Geneva, Switzerland. U.S. Pats. (A) 1,331,104 and (B) 1,331,105, 17.2.20. Appl., 4.1.19.

(A) NITROGEN oxides are recovered from a mixture with other gases by oxidation and subsequent liquefaction by refrigeration, the rate of oxidation being regulated so as to produce a mixture of oxides of nitrogen which will not solidify above 0° C. (B) Nitrogen oxides are recovered from a mixture with other gases by liquefying them at a temperature not exceeding -20° C. by means of a refrigerating liquid capable of dissolving nitrogen oxides without chemical interaction.—W. J. W.

Alumina; Manufacture of —. K. J. P. Orton and G. W. Robinson, Bangor. Eng. Pat. 139,005, 26.2.19. (Appl. 4827/19.)

AN aluminiferous mineral containing a high percentage of iron oxide, e.g., slate, is finely powdered and heated with 3—4 times its weight of nitre cake to a cherry-red heat for a short time. The product is lixiviated with water, and the slightly acid solution, diluted to about 15,000 parts per 100 parts of the mineral, is heated to 70°—80° C. until no more hydrated ferric oxide separates. Alumina and any remaining ferric oxide are precipitated from the filtered solution, and the ferric oxide is removed by the usual method.—L. A. C.

Zinc sulphate; Process for the purification of solutions of —. Comp. des Prod. Chim. d'Alais et de la Camargue, Paris. Eng. Pat. 139,443, 17.11.19. (Appl. 28,471/19.) Int. Conv., 12.9.19.

COPPER or/and cadmium sulphates present in a solution of zinc sulphate are removed by placing plates of copper or cadmium respectively and zinc, externally connected by an electrical conductor, in the solution. A difference of potential is set up between the two plates; copper (or cadmium) is deposited on the plate of the same metal, and the equivalent weight of zinc is dissolved from the zinc plate. A plate of carbon or of a metal less readily attacked than zinc by the SO₄ group is employed instead of copper or cadmium if the sulphates of both these metals are present.—L. A. C.

Ammonia-saturator. A. Roberts, Evanston, Ill., Assignor to American Coke and Chemical Co., Chicago, Ill. U.S. Pat. 1,331,784, 24.2.20. Appl., 17.4.15. Renewed 9.5.19.

THE apparatus comprises a tower closed at the upper end and communicating at its lower end with a hopper which has a bottom discharge, and is provided with a baffle parallel to one side. Slanting baffles project alternately from the opposing walls across the internal space of the tower over which the liquid flows from a connecting pipe at the top. Gas intake and discharge connexions communicate respectively with the bottom and top of the tower.

—W. J. W.

Carbon dioxide gas; Process of and apparatus for producing —. R. C. Newhouse, Wauwatosa, Assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,332,138, 24.2.20. Appl., 27.6.19.

A gas rich in carbon dioxide is produced by treating incandescent carbon with a compound containing oxygen under such conditions that the percentage of nitrogen in the product is a minimum, then burning the gas produced to calcine a carbonate, and collecting the resulting gases.—L. A. C.

Sulphur present in natural sulphates; Utilisation of —. Badische Anilin und Soda-Fabrik, Ludwigshafen. Ger. Pat. 305,123, 29.9.17.

THE gas obtained by heating sulphates, e.g., gypsum, and a combustible material in a current of air is separated from free sulphur, mixed with air, and passed over a catalyst consisting of an infusible material saturated with a solution of an iron salt. The catalytic material is first brought to the temperature required to start the reaction, but as the reaction proceeds, i.e., oxidation of carbon monoxide and sulphur compounds to carbon dioxide and sulphur dioxide, the heat of combustion is sufficient to maintain the desired temperature.—L. A. C.

Magnesium carbonate or ammonium magnesium carbonate; Manufacture of —. "Lipsia" Chem. Fabr., Mügeln. Ger. Pat. 306,335, 25.11.17.

A SOLUTION containing ammonium carbonate, such as the filtered liquor obtained in the ammonia-soda process, is treated with the requisite quantity of free ammonia, and added to a solution of a magnesium salt.—L. A. C.

Sulphur dioxide; Manufacture of — from calcium, barium, and strontium sulphites. Chem. Fabr. vorm. Weiler-Ter Meer, Uerdingen. Ger. Pat. 307,121, 23.3.18.

SULPHUR dioxide is prepared by heating calcium, barium, or strontium sulphite with magnesium salts, such as crude magnesium chloride or sulphate, or mixtures of the same.—L. A. C.

Nitrogen and hydrogen; Synthetic production of compounds of —. H. Harter and H. Braun, Berlin-Schöneberg. Ger. Pat. 310,623, 18.7.17.

IN the synthetic production of compounds of hydrogen and nitrogen the contact mass is constructed of iron tubes and rods. The rods are so treated that iron, ferrous oxide, and ferric oxide are all present in the mass. The conditions of the reaction are so adjusted that hydrogen peroxide is formed during the reaction, and to assist in its production suitable metals capable of combining with hydrogen are added to the iron. The contact mass is packed in a number of narrow iron tubes arranged within a wider iron tube.—L. A. C.

Salts; Removal of iron from inorganic —. E. Natho, Essen-Bredency. Ger. Pat. 315,837, 31.5.18.

SATURATED solutions of aluminium, potassium, and sodium sulphates can be freed completely from iron by treating them with sulphite-cellulose waste liquor; alternatively dilute solutions may be treated and then concentrated by evaporation; the iron is precipitated as iron-tannin compounds together with dextrans.—D. F. T.

Glauber's salt; Removal of iron from —. E. Natho, Essen-Bredency. Ger. Pat. 315,940, 31.5.18.

THE salt is treated with an oxidising agent, such as bleaching powder, and calcium chloride, and then heated to 400° C.; the iron is eliminated as volatile ferric chloride; if no oxidising agent is used a temperature of 1400° C. is necessary.—D. F. T.

Mercuric oxide; Manufacture of high-grade —. Consortium für Elektrochem. Industrie, Munich. Ger. Pat. 315,657, 1.5.18.

MERCURIC oxide containing much free mercury, such as is obtained by the electrolytic method of production, is treated with solutions of organic substances, preferably such as possess the character of protective colloids. The free mercury then separates rapidly from the suspension.—D. F. T.

Sulphur; Purification of —. J. J. Hood, London. U.S. Pats. (a) 1,331,615 and (n) 1,331,646, 24.2.20. Appl., 13.12.19.

LIQUID sulphur is passed through (a) ignited alumina or (n) ignited magnesia.—L. A. C.

Chlorides; Manufacture of metallic —. W. Hoop, Stockport, and E. Newbery, Manchester. U.S. Pat. 1,331,257, 17.2.20. Appl., 26.8.18.

SEE Eng. Pat. 131,039 of 1918; this J., 1919, 718 A.

Magnesium chloride; Production and utilisation of —. G. H. Bailey and G. W. A. Foster, Assignors to The British Aluminium Co., Ltd., London. U.S. Pat. 1,331,688, 24.2.20. Appl., 29.9.17.

SEE Eng. Pat. 109,996 of 1916; this J., 1917, 1177.

Ammonia; Production of — from cyanamide. B. Brodtkorb, Notodden, Assignor to Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania, Norway. U.S. Pat. 1,332,100, 24.2.20. Appl., 4.9.18.

SEE Eng. Pat. 120,034 of 1918; this J., 1919, 322 A.

Alumina; Manufacture of —. E. E. Dutt, Jabalpur, India. U.S. Pats. (a) 1,332,113 and (n) 1,332,115, 24.2.20. Appl., 18.10.18. (n) Renewed 29.11.19.

Water vapour. Eng. Pat. 137,547. See XXIII.

VIII.—GLASS; CERAMICS.

Glass batches; Use of mixtures of sulphate and water-glass as a substitute for alkalis in —. L. Springer. Sprechsaal, 1920, 53, 21.

VARIOUS mixtures of sodium sulphate and water-glass have been used as substitutes for other sources of soda in the manufacture of glass. The composition of water-glass varies considerably, but if the material is analysed and the results of the analysis used in calculating the amounts of soda, silica, and sodium sulphate required, the use of water-glass introduces no technical difficulty and increases the fusibility of the batch.—A. B. S.

Crystal glass; Use of specially pure Glauber's salt for the production of high-grade —. K. Killer. Sprechsaal, 1920, 53, 93-94.

GLAUBER'S salt can be used as the sole means of introducing soda into high-grade glass provided the salt is sufficiently pure. The chief impurities are sodium chloride, iron, and free sulphuric acid.

—A. B. S.

Soda-lime silicate glass; Electrical conductivity of —. R. Ambronn. Ann. Physik, 1919, [4], 58, 139-161. Chem. Zentr., 1920, 91, 11, 175-176.

MEASUREMENTS of the electrical conductivity of thirteen different glasses containing only Na₂O, CaO, and SiO₂ showed that the relation between conductivity and temperature can be expressed by a simple exponential equation in which the exponent is the reciprocal of the absolute tempera-

ture, and that the conductivity is zero unless the sum of the calcium and sodium atoms is at least 11 to each 100 atoms of the glass substance; in this connexion 1 atom Na is equivalent to 1 atom Ca.

—L. A. C.

Magnesia bodies. A. Berge. Sprechsaal, 1920, 53, 1—3, 9—11.

CERAMIC wares containing magnesia mature at a lower temperature than others, and the author has endeavoured to ascertain whether the use of magnesia bodies might be a means of saving fuel in the production of pottery. It was found that some of the German magnesium-bearing deposits are useful substitutes for the magnesite imported from Austria. The author examined 27 mixtures of magnesia with quartz, kaolin, and felspar, and describes the results obtained. It is concluded that the addition of magnesia is a suitable means of lowering the maturing point of various bodies without introducing serious technical difficulties. Some clay should be present in order to provide the necessary plasticity, about 10—15% being usually sufficient. Discoloration and blisters occur if the earlier stages of burning are hurried, as vitrification commences before all the carbonaceous matter has burnt out. The lower maturing point should effect a saving in fuel, but unless magnesia of sufficient purity can be obtained at a low price, the cost of the ware will not be reduced by the use of magnesia.—A. B. S.

Fireclay mixtures for high temperatures. R. M. Howe. Blast Furnace and Steel Plant, 1920, 8, 157—160.

VARIOUS materials which are commonly added to mortars made for use at high temperatures are often very harmful. They are added to increase the strength of the mortar at low temperatures and to reduce the shrinkage of the clay or porosity of the mixture. The addition of ground silica or alumina is useful, but Portland cement, lime, asbestos, water-glass, salt, and carborundum all lower the fusing point of fireclays to which they are added. The addition of 15% lowered the fusing point of fireclays to the following extent: Portland cement 320° C., lime 400° C., asbestos 250° C., water-glass 50° C., salt 500° C., and carborundum 20° C. A mixture of fireclay with 10% of asbestos and 10% of water-glass had a fusion point below cone 11 (1350° C.) as compared with 1730° C. for the clay alone. When this mixture was used as a mortar for laying bricks built four courses high and then heated under a load of 11 lb. per sq. in. to 1250° C., a large part of the mortar was fused and squeezed out of the joints. Arches similarly treated collapsed. The principal trouble in the use of fireclay alone as mortar is due to the shrinkage of the clay, and this may be avoided by the addition of a suitable proportion of grog or ground firebrick. Such an addition increases rather than diminishes the heat-resistance of the mortar and gives strong and firm joints even at 1350° C.—A. B. S.

Glazes; Transparent — for ivory and white ware. G. Heinstein. Sprechsaal, 1920, 53, 31—32, 44—46.

THE yellow colour of glazes containing lead oxide, alumina, or quartz is not suitable for ivory and white ware. The yellow tint disappears when the lead oxide is completely replaced by any other metallic oxide, and by replacing only 0.25 equivalent of lead oxide a good ivory glaze may be produced. If a little boric acid is added somewhat less lead may be used. The following three mixtures are recommended:—*Frit*: calcined soda, 15.90, 31.80, 44.70; chalk, 10.01, 20.02, 30.03; red lead, 17.32, 14.42, 57.11; Zettlitz kaolin, 7.76, 44.00,

43.00; quartz, 72.36, 75.38, 75.38; crystallised boric acid, 0.00, 62.03, 62.03; *Mill mix*: frit, 261.29, 289.62, 248.76; Zettlitz kaolin, 18.12, 20.70, 20.70 parts by weight. The first is suitable for ivory and inferior whites, and the second and third are suitable for ivory and good whites. Zinc oxide is the most satisfactory substitute for lead oxide in ivory glazes, but if alkaline-earth compounds must be used magnesia is the best substitute, then lime, strontia, and baryta in the order named. Zinc oxide and magnesia also reduce the tendency of the glaze to craze, except in the presence of boric acid.

—A. B. S.

Devitrification phenomena [in glazes], and their prevention. R. Berg. Sprechsaal, 1920, 53, 19—20.

WHEN a glaze which had been in regular use for earthenware was applied to wall tiles and fired in a wall-tile oven, at the same temperature, for the same length of time and using the same coal as before, it showed marked "blinding," especially near the edges. The defect was found to be due to the absorption of a portion of the glaze by the body, and it was cured by making the glaze more viscous by the addition of 5% of zinc oxide. If the slight opacity produced by zinc oxide is objectionable, the proportion of lime and potash or the total number of RO oxides may be increased.—A. B. S.

PATENTS.

Glass manufacture. B. G. Bealor, Aspinwall, Pa. U.S. Pat. 1,331,796, 24.2.20. Appl., 7.6.17.

AN apparatus for making glass consists of a tank, a glass-drawing well formed of refractory shields within the tank, a pair of movable refractory blocks, provided with fluid conduits and with their opposite faces spaced apart to an increasing distance at the glass-line as the blocks are increasingly immersed. Means are provided for drawing a sheet of glass from between the blocks in a plane at right angles to their faces.—A. B. S.

[Glass] colour-fitter or absorbing screen for artificial light. M. Luckiesh and D. A. Dewey, Cleveland, Ohio, Assignors to General Electric Co. U.S. Pat. 1,331,937, 24.2.20. Appl., 21.8.15. Renewed 29.11.19.

A COLOUR filter for giving the light of artificial illuminants the character of daylight is made of glass containing manganese, copper, and cobalt oxides in the proportion of 1 part of manganese dioxide to 2 parts of copper and cobalt oxides.

—A. B. S.

Quartz and other materials fusible with difficulty; Formation of hollow articles from — by means of an electric arc. Deutsch-Englische Quarzschmelze G.m.b.H., Charlottenburg. Ger. Pat. 315,539, 23.1.18.

AFTER the electrodes have been placed in position and the materials charged into an electric furnace an arc is started by ionisation of the intervening air instead of by means of a combustible conductor, to prevent contamination of the mould by the ash from the conductor.—J. A. C.

Quartz; Melting — by means of carbon resistances. Deutsch-Englische Quarzschmelze G.m.b.H., Charlottenburg. Ger. Pat. 317,421, 31.7.18.

BEFORE melting quartz by means of electrically heated carbon resistances embedded in the same, the resistances are heated for a sufficient time to volatilise impurities present in the quartz. The carbon is protected by a layer of sand or other suitable material, and should not be heated so long that the whole or a greater part of it is converted into graphite.—L. A. C.

[*Tunnel kiln for*] heat treatment of bricks, pottery, and the like. A. C. Ionides, jun., London. Eng. Pat. 139,267, 31.1.19. (Appl. 2470/19.)

Bricks, pottery, etc., are fired in a tunnel kiln divided into sections, the accommodation in each section being proportional to the time required in that stage of the heating or cooling. The goods are heated by passing the products of combustion of a mixture of gas and air through the corresponding part of the kiln. The firing section of the tunnel communicates with three parallel and connected preheating and cooling tunnels. Preheating is effected by radiation from the cooling goods, the cars carrying fresh goods passing along a central track with a track containing cooling goods on each side of it. The gas burners are placed in the side walls of the tunnel and are of the type described in Eng. Pat. 136,296. They may be provided with extended combustion passages (Eng. Pats. 108,701 and 114,223; this J., 1917, 1086; 1918, 229A) placed transversely across the cars, and are supplied with a mixture of gas and air at constantly related pressures, mixing being effected prior to ignition in proportions suitable for complete combustion. Additional tunnels may be provided adjacent to the other tunnels to serve as a drying chamber, which is heated by a directly fired air-heating device at the end of the chamber.—A. B. S.

Porcelain. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 139,315, 13.3.19. (Appl. 6303/19.)

In the manufacture of porcelain a portion of the free silica usually employed is replaced by zirconia or the oxide of some other rare metal. When a mixture of 45% of clay, 35% of felspar, and 15% of zirconia or zircote cement (containing 81% ZrO_2 and 14% SiO_2) is made into porcelain, the product may be heated to 800° C. and plunged into water without loss of mechanical strength. The modulus of rupture of such zirconium porcelain was found to be 7400 as compared with 4390 for ordinary porcelain. The electrical resistances of both porcelains are alike at ordinary temperatures, but at 286° C. that of zirconium porcelain was found to be 2.43 megohms and that of ordinary porcelain only 0.832 megohm. The zirconium porcelain is less porous than ordinary porcelain.—A. B. S.

Silicon carbide; Manufacture of —. O. Hutchins, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,331,435, 17.2.20. Appl., 15.7.19.

Silicon carbide is made in the usual manner from a furnace charge of silica and carbon, of which the upper portion is richer in silica than the lower portion.—A. B. S.

Enamel for enamelling articles in sheet metal or cast metal. C. Musiol, Brussels. U.S. Pat. 1,332,058, 24.2.20. Appl., 12.6.19.

A AORON-FREE enamel for sheet or cast metal is composed chiefly of a triple silicate of aluminium, sodium, and calcium, mixed with a fluoride.

—A. B. S.

Furnaces. Eng. Pat. 139,276. See X.

IX.—BUILDING MATERIALS.

Portland cement raw mixture; Analysis of —. J. C. Witt. Philippine J. Sci., 1919, 15, 107—120.

THE methods employed for determining the calcium carbonate content of Portland cement raw mixture (on which the proportioning of the materials is usually based) are critically surveyed, attention being drawn to the causes of errors due to the

nature of the constituents themselves and to the various kinds of apparatus and procedure adopted.

—W. E. F. P.

Cement; Effect of fineness of —. D. A. Abrams. Proc. Amer. Soc. for Testing Materials, Vol XIX. Part II., 1919. Bull. 4, Structural Materials Research Lab., Lewis Inst., Chicago.

A LARGE number of experiments have been made on the effect of fineness of grinding of Portland cement on the qualities of the concrete made from it. The experiments covered fifty-one different samples from seven commercial mills, and the cements were ground to four to seven degrees of fineness; the amount of residue left on a No. 200 sieve by the different samples varied from 2 to 43% of the cement. For a given sample of cement, the strength of the concrete increased with the fineness for all proportions of mixture, consistencies of the wet concrete, qualities of the aggregate, and ages of the concrete; but the strength of the concrete does not vary according to the fineness of the cement if different cements are used. The fineness of the cement has a greater effect in increasing the strength of concretes having a small proportion of cement, but the effect decreases with the age of the concrete. An increase in strength of from 2.5 at 7 days to 1.4% at 12 months is shown for each 1% reduction in the residue of the cement on the No. 200 sieve. The hardening of the concrete is thus accelerated by finer grinding of the cement. The density of the concrete and its expansion or contraction when stored in water or air respectively are not dependent on the fineness of the cement. With the usual concrete mixtures containing 20 to 25% of cement, the strength was increased about 1% by an increase of 1% in the cement content, and an increase in the proportion of cement had a greater effect on the strength of poor mixtures than on rich mixtures. The strength of the concrete varied inversely with the amount of water used, and a stronger concrete may be obtained with equal ease of working by using a larger proportion of cement.

—W. F. F.

Slags; Disintegration of blast furnace —. K. Endell. Stahl u. Eisen, 1920, 40, 213—222, 255—262.

CHEMICAL analysis does not give any definite means of distinguishing stable slags from unstable ones, though a high proportion of magnesia and alumina or more than 5% $FeO+MnO$ appears to favour stability. Thin sections of various slags were examined microscopically. As a rule stable slags contain notable quantities of the following groups of minerals distributed in a ground mass of indeterminate composition: melilites, resembling those found in some basalts, with a flocculent and zonal structure, feeble double refraction, refractive index above 1.51, straight extinction, optically monoaxial with negative sign; a second series of melilites with the same general optical characters, but greater refraction due to the introduction of ferrous or manganous oxide; varieties of olivine; opaque skeletons of magnetite or manganese oxides present in slags rich in iron and manganese; fern-like globulites of manganous and ferrous sulphide which appear to be characteristic of stable slags. Unstable slags are largely composed of disintegrating melilites, readily distinguished in polarised light by their grey blue colour and the characteristic appearance of their edges, by their higher degree of refraction and yellowish red interference colours. Variations in structure occur in old slags and in some of a special character. The stability or otherwise of a fresh slag can be predicted with a fair degree of certainty by micro-petrographic investigation, as stable slags do not contain disintegrating melilites after being exposed to the weather for two or three weeks.

Unstable melilites which do not disintegrate on weathering are formed by very rapid cooling and occur in the outer crust of large blocks of slag and in slag which has been allowed to flow through troughs. This is due to the fact (previously established by the author) that ferrous and manganous oxides rapidly diffuse from the molten interior to the cooler exterior of a silicious mass, thus enriching the latter and making it more stable than the former. The more slowly cooled interiors of large blocks frequently contain altered melilites which eventually cause the slag to fall to powder. On reheating for 48 hours at 1200° C. stable slags are not affected, but unstable ones show a large increase in the number of fragments of melilite, the increase being roughly proportional to the rapidity with which the slag was originally cooled. The changes effected by reheating are only visible in thin sections under the microscope. An increase in the size of the crystalline grains also occurs. An examination of a series of synthetic basic slags corresponding to those obtained in the Thomas and Gilchrist process of steel manufacture showed that the disintegration of slags is not likely to be due to calcium orthosilicate, but to mixed crystals of calcium aluminosilicates (melilites); and that the presence of manganous oxide or a mixture of manganous and ferric oxides in a slag increases its stability. Synthetic basic slags containing 11–13% Al_2O_3 and 3–4% Fe_2O_3 and/or MnO disintegrated readily, but those containing 17% Al_2O_3 were more stable, and those containing 21–22% Al_2O_3 showed no signs of disintegration. Similarly, synthetic slags containing 10% or more MgO were quite stable. Any disintegration likely to occur in large masses of slag takes place within the first fortnight. Disintegration is not primarily due to the chemical composition of the slag, but to its physical structure. Slags which are more than six weeks old and have shown no obvious signs of disintegration may safely be used as aggregate for concrete. The metastable constituents found in some slags are highly stable under ordinary atmospheric conditions.—A. B. S.

Light-weight artificial stone from blast-furnace slag; Schol process for the manufacture of —.

A. Guttmann. Stahl u. Eisen, 1920, 40, 326–331. The blast-furnace slag used as raw material should contain 35–38% SiO_2 and not less than 47–44% CaO . Manganese and magnesia should be present in small proportion only. The slag is prepared in a light and highly porous condition by projecting the molten material in a horizontal direction into a limited quantity of water so that the process is aided by the development of steam. The spongy mass has apparent specific gravity 0.14–0.22, and forms a serviceable insulator against heat and sound. It is crushed, sifted, and the portion between 3.5 and 12 mm.-mesh size used as basis. The moistened fines are mixed with quicklime in proportion 3:1. The latter is thereby slaked and more dry fines are added to bring up the proportion to 85%. This constitutes the cementing material. One part of cement and six parts of the granular basis are mixed wet and the product pressed into brick form in moulds. The bricks are subjected to steam heat at 60°–80° C. for 6–8 hrs., whereby considerable hardening occurs owing to the hydraulic properties of the mixture. The hardening continues when they are stored for a month in the open. This may be accelerated by a hardening under high-pressure steam.—H. J. H.

Refuse destruction. Grempe. See XIXb.

PATENTS.

Artificial stone or slabs of marble-like appearance; Production of —. H. Grönroos, Copenhagen. Eng. Pat. 138,799, 4.6.19. (Appl. 14,182/19.)

A moist mixture of equal parts of powdered porce-

lain or pottery, pipeclay, and glass-refuse is compressed in a mould under a pressure up to 2850 lb. per sq. in., and the resulting slabs are heated to 900°–1200° C. for 15 mins. so as to fuse the glass. When a glossy surface is required, a layer of crushed glass refuse is placed in the bottom of the mould prior to filling it with the mixture.—A. B. S.

Thermal insulating bodies; Manufacture of —.

H. J. C. Forrester, Birmingham. From International Isolations Kompani A./S.-Ikas, Christiania. Eng. Pat. 139,318, 15.3.19. (Appl. 6522/19.)

A HEAT-INSULATING material is made by mixing 2 parts of dried and finely ground "moler" (diatomaceous earth) with 3 parts of a granular or gritty substance such as dressed cork, peat, sawdust, etc., which has previously been heated to 150°–200° C. to cause it to expand and drive out part of the air and so prevent damage to the moulded pieces later. Water in small quantities is added slowly to the mixture with continual stirring until it attains a dough-like consistency, and the mass is then moulded, dried slowly, heated slowly to 250° C. and afterwards to about 1000° C. The final product has sp. gr. about 0.3.—A. B. S.

[Plaster] mixture; Plastic — and process for making the same. M. K. Armstrong, Winnetka, Ill. U.S. Pat. 1,331,554, 24.2.20. Appl., 2.7.19.

A PLASTER is made by deflocculating clay or clay soil in a fluid in the presence of an electrolyte and adding finely ground calcined gypsum.—A. B. S.

Kilns for burning cement etc. Ger. Pat. 315,775. — Sec I.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Ore-oxygen gasified directly or indirectly in the blast-furnace; Method for calculating the proportion of —. H. Thaler. Stahl u. Eisen, 1920, 40, 317–321.

THE reactions of oxygen in the iron blast-furnace are of three types:—(1) $\text{C} + \text{O} = \text{CO}$, (2) $\text{MO} + \text{C} = \text{M} + \text{CO}$, and (3) $\text{MO} + \text{CO} = \text{M} + \text{CO}_2$. Reaction 2 may be termed "direct" reduction and reaction 3, "indirect" reduction of the ore. If the material balance sheet of the furnace operation is known it is possible to calculate to what extent the direct and indirect processes contribute to the production of iron from its ore, and thus form an opinion as to the efficiency of operation. Indirect reduction corresponds to greater thermal economy and represents the ideal, although in normal practice only 60–65% of the reduction is of this type. In the results of eight calculations the lowest figure was 36.4%, and the highest 69.4%. When the actual CO content of the blast-furnace gas exceeds that theoretically obtainable from the blast alone, the "direct" gasified ore-oxygen equals three-fourths of the total gasified ore-oxygen plus one-fourth of the difference between the oxygen content of the CO actually in the gas and that obtainable from the blast alone, minus three-fourths of the oxygen content of the difference between the actual CO_2 content of the blast-furnace gas and that in the charge. If the CO content of the gas is less than that theoretically obtainable from the blast, the "indirect" gasified oxygen equals one-half the sum of the total gasified ore-oxygen and the difference between the oxygen content of the CO obtainable from the blast and that actually present in the gas.—H. J. H.

Blast furnaces; Comparison of electric and coke-fired —. M. Guédra. Rev. Mét., 1919, 17, 13–15.

In electric blast-furnaces at Trollhättan the heat

expended in obtaining 1000 kilos. of pig iron was 2,155,262 cals. The author's trials on coke-fired blast furnaces of 90 tons capacity using 1100 kilos. of coke per ton showed that 3,927,130 cals. was required to produce 1000 kilos. of pig. Thus there is a difference of 1,771,863 cals. in favour of the electric furnace, although only 60–70% of the electric energy was utilised. The calorific value of 1 kilo. of gas from the electric blast furnace is 2257 cals., against 638 for the coke-fired furnace. On account of the greater quantity of gas produced in the latter the total calories per ton of cast iron is 3,582,370, against 1,665,485 for the electric furnace, but a large part of the gas produced in the coke furnace is used to heat the blast to about 720° C.—T. H. Bu.

Coke-oven gas; Heating of a Martin furnace with cold —. F. Springorum. *Stahl u. Eisen*, 1920, 40, 9–13.

Gas, low in sulphur and with a high hydrogen content, is brought directly from the coke ovens and introduced at atmospheric temperature along with a blast of air into the furnace by means of tuyères. The tuyères are situated at either end of the furnace, the direction of the gas being regulated by means of reversible valves fitted with water-seals. The gas burns with a scarcely visible flame, giving a reducing atmosphere over the bath of metal. Tests of a few months' duration were carried out on two Martin furnaces of 30 and 100 metric tons capacity respectively, and the output and quality of the steel compared favourably with the output and quality of the steel from the same furnaces heated by means of ordinary producer gas.—J. W. D.

Heating metallurgical furnaces with heavy oil. A. Gouvy. *Chim. et Ind.*, 1920, 3, 143–156.

PETROLEUM in Russia during the war with the use of petroleum residue (mazout) has shown that heavy oil can be used with advantage for metallurgical furnaces. For the heat treatment of shells and for metallurgical work in general it is preferable to atomise the oil by compressed air and to avoid the use of steam. A cutting blowpipe flame which would burn the surface of the metal is avoided by providing a combustion chamber in front of the treating chamber so that the latter is filled with a tranquil flow of hot gas. The complete combustion of the oil is ensured by providing in the combustion chamber a bridge wall which becomes incandescent. For boiler firing the oil is atomised by steam into a brick-lined combustion chamber.—W. H. C.

Metallurgical processes in the acid and basic converter on the basis of spectro-analytical observations. L. C. Glaser. *Stahl u. Eisen*, 1919, 40, 73–80, 111–117, 188–191.

THE application of the spectroscope to the study of the converter flame yields additional information to that derived from its visual appearance, and besides portraying the purely metallurgical processes enables conclusions to be drawn as to the temperature and fluidity of the bath. Results of spectroanalytical observations on the acid process show that it is possible to ascertain when a desired carbon content has been reached and to control the composition of the metal bath. This results in a saving of additions. The heats can be satisfactorily tapped according to the spectrum. The spectroscope as applied to small Bessemer working is of value in determining the time of ignition of the carbon and in controlling the composition of the bath when making special material and producing cast ingot iron. In the case of the basic process it is possible by ascertaining the point of lowest carbon content to determine the degree of dephosphorisation. In both processes it is possible to judge the

progress of the blow, and to measure and regulate the necessary additions of scrap.—T. H. Bu.

Chrome-nickel steel; Influence of deoxidation and duration of solidification on electro —. E. Kothny. *Stahl u. Eisen*, 1920, 40, 41–45.

CHROME-NICKEL steel (C 0.40, Mn 0.42, Si 0.22, P 0.030, S 0.015, Cr 0.18, Ni 2.51) was prepared in an Héroult furnace and just sufficient ferromanganese and ferrosilicon added to remove red-shortness. The bath was then treated with two oxidising slags and half the charge at once poured. More ferromanganese was added to the steel remaining in the furnace, and, after half an hour, the second half of the charge was poured. Each half was cast into 3 ingots, the first portion being poured into a well heated sand mould, the second portion into an iron mould previously heated to 400° C., and the remainder into an iron mould at 50° C. The time taken for solidification of the two "sand" ingots was 35 min., and that for all four ingots cast in iron moulds was 13–15 min. The "sand" ingots solidified suddenly throughout, and showed a coarsely crystalline uniform structure when broken. The iron-mould ingots solidified progressively from the outside towards the centre and gave corresponding fractures. The fractures gave no indication of the difference in deoxidation treatment. The ingots were rolled down from 230² to 110² sq. mm. cross-section, and annealed for 10 hours at 700° C. Tensile and impact test-pieces were then prepared, some of which were tested without further treatment, and others after being quenched in water from 820° C. and reheated for 15 min. at 600° C. and at 250° C. respectively. The results showed that the quickly solidified, well deoxidised material corresponded in every way to commercial standards, but that incomplete deoxidation gave rise to a granular structure, and slow solidification to a fibrous structure in the heat-treated steels.—T. St.

Gold ore; An unusual process in the treatment of —. B. L. Gardiner. *J. Chem. Met. Soc.*, S. Africa, 1920, 20, 109–117.

THE ore consists of granulated quartz mixed with oxides and hydroxides of iron, and containing also a certain amount of iron and magnesium sulphates. Direct cyaniding extracted only about two-thirds of the gold, the remainder being so entangled in, and coated with oxidised iron compounds that finer grinding, preliminary acid washes, or the use of stronger solutions of cyanide did not improve the extraction. By baking the ore at 200°–300° C., however, iron hydroxides were decomposed with the formation of a porous mass of ferric oxide from which the gold was readily leached, an extraction of 90% being obtained in the laboratory. To carry out the process on the large scale a rotary dryer was used. Only that part of the ore which passes a screen of 1½ inch aperture is treated in the dryer, the remainder being treated in the usual way. The ore, as it comes from the dryer, is mixed with slaked lime (10 lb. per ton) and dumped into the sand leaching vats. By working in this manner the extraction was increased from about 63% to 86% at a cost of about 2s. 2d. per ton.—A. R. P.

Gold-silver alloys; Action of aqua regia on — in the presence of ammonium salts. W. B. Pollard. *Chem. Soc. Trans.*, 1920, 117, 99–103.

GOLD-SILVER alloys after a short time resist the action of aqua regia owing to the formation of a protective coating of silver chloride on the surface of the metal, but complete solution may be readily effected in the presence of ammonium chloride, or ammonium chloride and nitrate. With 5 grms. of each salt and 5–10 c.c. of aqua regia 0.5–1.0 gm. of alloy can be easily and quickly dissolved. On diluting the solution with water the silver chloride

is completely precipitated. A secondary reaction occurs during solution whereby some of the ammonia is oxidised to nitrogen, and also in some cases the formation of purplish-brown crystals, having the composition $3\text{AgCl}\cdot 4\text{AuCl}_3\cdot 8\text{NH}_4\text{Cl}$, was observed. This double salt is immediately decomposed by water with precipitation of silver chloride.

—G. F. M.

Powdered coal; Utilisation of — for heating copper smelting furnaces. G. de Venancourt. Rev. Mét., 1920, 17, 2—12.

THE theoretical advantages attending the use of pulverised fuel are found to be confirmed in practice in the case of reverberatory copper-smelting furnaces. The feed hoppers for the ore charges are best placed in double line on either side of the furnace. The material in the furnace is then continuously exposed to the gases of combustion and protects the sides from the heat. The output of the furnaces is increased even with inferior grades of fuel. Particulars of trials on furnaces of the water-jacket type are given, the furnaces being found to retain their heat well. Trials made by the Tennessee Copper Co. showed that a smaller percentage of coal was required than when coke was used for heating by previous methods. In a new type of furnace the pulverised coal was introduced independently of the air. With 50% coke in the charge the results were satisfactory, but not entirely when using powdered coal alone. Nearly all coals, even lignites, may be employed, but they must be dry, very fine, and contain a certain quantity of volatile material.—T. H. Bu.

Copper; Standardisation of —. O. Nielsen. Metall u. Erz, 1920, 17, 4—10.

THE author reviews previous proposals for standardising copper specifications, and also the current specifications of many railways etc. He recommends that the properties specified should be confined to those which come into question in the service for which the copper is required. Thus a specification stating the conductivity requirements should suffice for copper for electrotechnical purposes, except in special cases when it would be necessary also to specify certain mechanical properties. Only in the case of copper required for the preparation of alloys is it necessary or desirable to define the chemical composition.—T. St.

Zinc furnace; The combustion chamber of the Hegeler —. O. Mühlhaeuser. Metall u. Erz, 1920, 17, 1—4.

THE furnace is divided into two similar portions by a dividing wall which runs the whole length of the furnace and serves to support the back ends of the muffles in both portions. Each portion is divided into 18 sections, and each section contains 24 muffles in six rows of four, one above the other. Producer-gas is supplied at one end of the furnace to both portions equally, and passes forward through all the sections on either side of the central wall, air being supplied separately to each section in amount sufficient to consume an aliquot part of the gas. The air may be preheated, and the exhaust gases on leaving the last sections may be utilised for this purpose, or for heating boilers, or both. Baffle arrangements are provided between the sections to mix the gases in the gas stream and so ensure uniform heating of all the muffles.—T. St.

Zinc retorts; Permeability of —. O. Mühlhaeuser. Metall u. Erz, 1919, 16, 191—195, 219—233.

IN a series of experiments, each lasting several weeks, carried out to determine the permeability of the retorts during zinc distillation, daily determinations were made of the pressure in the furnace and in the retort, and of the nitrogen content of

the retort gases. From the tabulated results the author draws the following conclusions. The permeability of a new retort depends on the porosity of the material and the nature, length, depth, and number of small fissures developed during the drying, baking, and heating up in the furnace. It steadily diminishes during the first fortnight of use, and eventually attains an almost constant value which varies for each retort in the furnace. This is attributed to the gradual filling up of the cracks by the glazing of the outside of the retort by the heat, and by molten slag dropping from the roof of the furnace, as well as to the alteration in the chemical nature of the clay (transformation of the alumina and silica into zinc spinel, tridymite, and sillimanite). The permeability sometimes increases abnormally for a day or two and then falls back to its original constant value. This may be due to overheating of the retort, thereby loosening the glaze, or making it more liquid and, therefore, less able to withstand the pressure of the gases, or it may be due to the development of new fissures which are then gradually filled up from either the inside or the outside of the retort. The former condition may be counterbalanced by an increase of slag within the retort or by the oxidising action of the flame causing the separation of ferrite from the ferrous silicate and thus rendering it more viscous.

—A. R. P.

Zinc; Polishing and etching of — for micro-examination. H. H. Hayes. Inst. of Metals, 12.4.20. [Advance copy.] 1 page.

To study the effects of different methods of annealing zinc the following rapid method of polishing and etching was developed. After polishing on standard French emery papers the specimen is rubbed on chamois leather smeared with "Globe" polish and finally with the tip of the finger, then cleaned with water-free ether and dried in a hot air blast or on linen. The micro-section is held in zinc-tipped forceps and immersed in fuming nitric acid (sp. gr. 1.5) for 1 min. and immediately rinsed in water and dried in a hot air blast.—T. H. Bu.

Zinc; Solubility of — in cyanide solutions. H. A. White. J. Chem. Met. Soc., S. Afr., 1919, 20, 97—101.

WEIGHED and measured strips of thin sheet zinc were subjected to the action of solutions of potassium cyanide and calcium hydroxide for various periods, under conditions similar to those obtaining in practice during the precipitation of gold in extractor boxes; and the amounts of zinc dissolved per unit of area exposed were calculated. The consumption of zinc by cyanide in the presence or absence of free alkalinity, was greatly reduced by de-aerating the solutions; and the amount dissolved by aerated cyanide solutions was much greater when the metal was in contact with carbon than when in contact with lead. In aerated solutions containing 0.03% KCN, the degree of alkalinity had little effect on the rate of solution of zinc, whether the latter was freely suspended or in contact with lead. Alkalinity equivalent to 0.03% NaOH did not interfere with the precipitation of gold from cyanide solutions; but, in the absence of cyanide, practically no zinc was dissolved by lime water of strength equivalent to 0.04% NaOH. From de-aerated solutions of potassium aurocyanide no gold was precipitated by zinc, alone or in contact with lead, in the absence of free cyanide; and the best precipitation of gold was obtained by the use of a zinc-lead couple in solutions containing free cyanide. It is concluded that close regulation of cyanide strength, alkalinity, and aeration of the solution is necessary to keep the consumption of zinc within reasonable limits; and that a zinc consumption corresponding even approximately to the amount of gold precipitated is not attainable.—W. E. F. P.

Brass; Casting in high tensile —. N. J. Maclean. Inst. of Metals, 12.1.20 [Advance copy.] 18 pages.

Is experiments to produce an alloy which when cast in sand moulds would give results 50% better than Admiralty gun-metal, additions of manganese, vanadium, titanium, and cadmium, and later nickel and iron, to brass were tried. The alloy finally chosen was Cu 60%, Zn 31%, Ni 3%, Fe 2%, Pb 0.25%, Mn 0.5%, phosphor-tin 0.25%. A special hardener consisted of Cu 75%, Ni 15%, Fe 10%, which was melted in a crucible and granulated by blowing a stream into a tank of water. Special precautions were taken to keep the zinc content of the alloy and the pouring temperature constant. Scrap metal was melted into ingots, which were analysed. The charge was then made up of scrap, new metal, a quantity of hardener, and zinc. The alloy gave sound castings which, cast in sand moulds, had a breaking strength of 20 tons per sq. in., an elastic strength of 10 tons per sq. in., and an elongation of 15% on 2 ins.—T. H. Bu.

Aluminium; Action of hard waters on —. R. Seligman and P. Williams. Inst. of Metals, 11.4.20. [Advance copy.] 25 pages.

OXYGEN is absolutely essential to attack on aluminium by water. The presence of impurities in the aluminium is not on the whole detrimental, the electro-positive metals serving to restrain corrosion. Hard worked metal is attacked relatively easily, but corrosion does not predominate on hardened spots. The composition of the water is the chief factor, pitting being definitely dependent on the simultaneous presence of the chlorides and bicarbonates of either calcium or sodium and probably other metals. Corrosion is always accentuated where the products of corrosion can accumulate. The formation of blisters may be due to the presence of cavities in the aluminium. Treatment of the aluminium to augment the protective film of oxide normally covering the surface gave only slightly enhanced resistance, but chemical treatment of tap water is capable of removing its property of pitting aluminium. Additions of lime water and of small quantities of nitrates or chromates are effective. Effective protection can be obtained by use of an outside source of electricity or by contact with a more electro-positive metal such as tin or zinc.—T. H. Bu.

Aluminium; Protective coating for —. L. von Grotthuss. Metall u. Erz, 1920, 17, 39—40.

ALUMINIUM sheets are given a protective coating by making them the cathodes in a bath, maintained at 60°—65° C., consisting of a solution of a sulpho-compound of molybdenum, zinc sheets forming the anodes. After a short time the aluminium becomes coated with a dark-brown to black deposit which withstands rolling, bending, etc. Sheets thus protected are unaffected by tap- or sea-water.—T. St.

Lead sulphate; The problem of reducing —. F. N. Flynn. Eng. and Min. J., 1920, 109, 487—489.

THE usual method of working up fume containing lead sulphate by extraction of the zinc with sulphuric acid and smelting of the residue in the blast furnace after briquetting, presents considerable difficulties, and the author proposes the following wet method. The wet material is dried, and any acid evolved is recovered. The dry residue is extracted with a nearly saturated solution of sodium, calcium, or magnesium chloride containing a certain amount of ferrous chloride or other easily oxidisable salt to act as depolariser. After settling the clear liquor, containing approximately 1% of lead, is decanted and electrolysed using a lead or iron cathode and an insoluble anode (e.g., graphite,

magnetite, duriron). The amount of ferrous chloride present must be greater than that equivalent to the amount of lead precipitated during the operation. When the electrolyte contains only 0.01% of lead the electrolysis is stopped and the solution is treated with sulphur dioxide or calcium sulphite to reduce ferric chloride, and then agitated with lime to precipitate the accumulated sulphuric acid and thus preserve the solvent action of the solution for lead sulphate. This purified solution is used over again in the process. The lead is precipitated as an adherent deposit on the cathode, as nodules, and as powder. The cathodes are washed, melted and cast into pigs; the nodules and powder, after washing, are melted in a dross reduction furnace.—A. R. P.

Dross losses in metal melting. E. H. Schulz and H. Winkler. Metall u. Erz, 1919, 16, 215—218.

THE amount of dross produced on melting brass increases with the zinc content of the alloy and also with the fineness and degree of oxidation of, and amount of impurities in, the scrap-metal added. Thus, on melting a 2½-ton charge consisting of 67% scrap and 33% new metal a loss of 4% was obtained, whereas when the mixture consisted of 80% scrap and 20% new metal, the loss was 11% of the charge, and the relative amount of copper lost was also greater. An alloy of zinc with 2.89% of copper and 3.75% of aluminium was made by melting the latter two metals separately in small furnaces, pouring them into the molten zinc contained in crucibles, and casting the alloy in iron moulds. After removing any prills of metal from the dross and allowing for this, 0.51% of the zinc, 11.80% of the copper, and 12.20% of the aluminium were lost as dross. The total metal loss calculated on the final alloy was 1.4%, of which that due to zinc was 0.48%, to copper 0.39%, and to aluminium 0.53%. Two charges of zinc-aluminium (2.5% Al) alloy scrap were melted down, the first, consisting of 50% finely divided and strongly oxidised material and 50% of coarser and cleaner scrap, gave 69% of clean alloy; the second consisting entirely of the dirty scrap, yielded only 40.5% of alloy. These considerable losses were due to the large amount of oxidised material present holding up the metal so that it was necessary to employ a high temperature in melting with consequent volatilisation and oxidation of much of the zinc. Similar losses were obtained in melting scrap zinc; they varied from 10% to 26%, according to the amount of finely divided and dirty scrap present. Scrap aluminium is usually melted in a reverberatory, and the difficulty of separating metal and dross is much greater on account of the low specific gravity of the former. Hence the losses to be expected depend to a much larger extent on the amount of dirty and oxidised material present, and, while a loss of only 5% may be experienced with careful working on sheet or other coarse form of metal, with very fine, and oily turnings, the loss is likely to be over 20%.—A. R. P.

Welding; Comparison of the different methods of —. P. Schimpke. Metall, 1919, 243—245. Chem. Zentr., 1920, 91, II., 81.

WELDS made by the use of a coke fire or water-gas give the strongest joints. The use of hydrogen is economical only for sheets up to 5 mm. thickness. Acetylene-welding is superior to all other methods for sheets, whilst for thicker material (up to 12 mm.) water-gas is superior. Benzol-welding costs 50% more than acetylene welding, while the use of coal-gas is about as expensive as that of hydrogen. Welding in a coke fire is the most costly method. Autogenous and electrical welds are considerably stronger than soldered joints.—A. R. P.

PATENTS.

Steel; Rail —. C. H. Wills, Detroit, Mich. U.S. Pat. 1,331,175, 17.2.20. Appl., 6.7.17.

STEEL of the following composition C 0.35—0.055%, P not to exceed 0.1%, Si not to exceed 0.27%, Mn 0.7—1.10%, and Me trace—1.0%, is quenched from 1500°—1650° F. (815°—900° C.) and drawn at 1000°—1200° F. (540°—650° C.).—J. W. D.

Nickel-manganese steel; Process for improving non-magnetic —. F. Theubert, Berlin-Weissensee. Ger. Pat. 310,101, 19.5.18.

By the addition of 1—6% of silicon to nickel-manganese steel the elastic limit and specific electrical resistance are raised and the alloy can be more easily worked, while its non-magnetic character remains unaltered.—A. R. P.

Steel alloy. Stahlwerke R. Lindenberg A.-G., Remscheid-Hastent. Ger. Pat. 316,149, 18.7.15. Addition to 299,192.

A HARD and highly tenacious steel contains 0.1% less carbon than that described in the chief patent (this J., 1919, 908 A); if a case-hardened steel is required the carbon content is 0.08—0.15%.

—L. A. C.

Nickel-plated iron and steel objects; Process for preventing — from rusting. E. Kronenberg, sen., Seligen. Ger. Pat. 316,053, 2.12.17.

IRON or steel objects are heated in oil at 200° C., cooled, freed completely on the surface from oil, covered with a thin coating of copper, nickel-plated in a citric acid nickel bath using a weak current, and dried at 200° C.—L. A. C.

Heat treatment of metals; Furnaces for —. H. W. Brighton and P. Peakman, Manchester. Eng. Pat. 138,981, 4.2.19. (Appl. 2737/19.)

A CLOSED muffle heated externally by means of producer gas is combined with a generator for supplying gas to the interior of the muffle. The gas leaving the muffle is used to assist in heating it externally. Partially carbonised fuel from the generator is conveyed to the producer, where carbonisation is completed.—J. W. D.

Furnaces for hardening or tempering steel tools or for heating or annealing metals, glass, pottery, or the like. J. R. C. August, Halifax. Eng. Pat. 139,276, 12.2.19. (Appl. 3410/19.)

A GAS-fired furnace in which the combustion chamber has inclined sides, a roof with a rounded corner or baffle between the gas supply jet and the combustion chamber orifice, and a floor which gradually slopes upwards from the end where the gas and air are delivered to the end where they enter the furnace. The pipes for supplying the gas and air pass back and forth through a series of chambers connected by spaced conduits giving a good heating surface, these chambers being cast inside a hood arranged on the top of the furnace and heated by the products of combustion from the furnace.

—J. W. D.

Conglomerates of fine ores, iron filings, flue dust, purple ore, and the like; Solidifying —. C. Giesecke, Harzburg, Germany. Eng. Pat. 139,229, 4.10.16 (Appl. 3369/18.)

BLOCKS or masses of fine ore or the like formed in a press are fed evenly, together with finely-divided fuel into a shaft furnace, wherein they are submitted to such a degree of heating and subsequent cooling and are caused to pass through the various

zones of the furnace with such rapidity that the sintering heat does not extend to the core of the agglomerated masses, whereby a conglomerate is produced having a well-sintered crust with a less sintered or completely unsintered and consequently easily reducible core.—J. W. D.

Alumino-thermic method; Manufacture of metals and alloys by the —. British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 139,247, 3.1.19. (Appl. 212/19.)

FERRO-zirconium or ferro-silico-zirconium is produced by forming briquettes of the oxides of the metals, intimately mixed with finely-divided aluminium, a portion at least of which is in the flaky condition, and then igniting the briquettes.

—J. W. D.

[*Aluminium*] *solder.* Miralite, Ltd., and W. G. Grever, London. Eng. Pat. 139,402, 21.7.19. (Appl. 18,141/19.)

A SOLDER for soldering aluminium and alloys rich in aluminium consists of Al 2.4, P 2.4, Zn 26.2, Sn 69%.—T. St.

Flotation apparatus and process. J. M. Callow, Salt Lake City, Utah, and H. P. Corliss, Pittsburgh, Pa., Assignors to Metals Recovery Co., Augusta, Me. U.S. Pat. 1,331,238, 17.2.20. Appl., 3.7.19.

IN a flotation apparatus the air is delivered through a porous layer composed of a mixture of a synthetic resin and a granular substance moulded into form and hardened by the application of heat.—T. St.

Copper; Process for hardening —. D. T. Beckham, Geneva, Tex. U.S. Pat. 1,331,479, 24.2.20. Appl., 13.3.19.

COPPER is hardened by heating it to a high temperature and then subjecting it to continual pressure until cold.—T. St.

Smelting-furnaces; Open-side water-jacket for —. A. B. Carstens, Monterey, Mexico, Assignor to The American Metal Co., Ltd., New York. U.S. Pat. 1,331,803, 24.2.20. Appl., 1.10.18.

A WATER-JACKET for a metallurgical furnace, forming, for example, the bosh wall of a blast furnace, consists of a series of superposed separable cells arranged to overflow successively from one to the other and from the top to the bottom of the jacket.

—T. St.

Furnace; Open-hearth —. F. Carter, Minneapolis, Minn., and D. McLain, Milwaukee, Wis. U.S. Pat. 1,331,804, 24.2.20. Appl. 12.3.17.

A NARROW furnace chamber with a high roof and contracted end portions is provided with vertical air-intake ports extending the full width of the contracted portions, and inclined oil burners, which pass through the end walls of the furnace chamber and extend across the path of air from the vertical ports.—T. St.

Roasting furnace. H. Alinder, Assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,332,152, 24.2.20. Appl., 2.4.17.

IN a furnace with superposed hearths the rabble arms carried by the central vertical shaft are detachable, and when in position are secured by a projecting locking device.—T. St.

Roasting zinc-blende or other material containing sulphur; Process and furnace for —. Fellner und Ziegler, and W. von Escher, Frankfurt. Ger. Pat. 312,383, 21.12.17.

THE roasting gases are led backwards over a fresh charge of ore in order to preheat and ignite it,

after which the gases pass forward again thereby completing the roasting. The operation is carried out in a furnace consisting of two rotating tubes, one above the other, the lower tube being progressively widened towards the discharging end. The air is led in at the charging end of the tube in which the final roasting is carried out, and prevented from overflowing into the other tube. At the discharging end of the former tube the hot gases pass into the second tube and ignite the charge therein. Working in this manner it is claimed that no external heat is necessary, as the final roasting is carried out in the presence of the hottest gases.—A. R. P.

Martin furnace; Process for substituting coke or the like for pig iron in operating a —. Thyssen und Co. A.-G., and F. Thomas, Mülheim. Ger. Pat. 316,027, 21.1.16.

COKE covered with a protective layer of milk of lime, calcium sulphate paste, water-glass, or the like, is added to the charge of a Martin furnace instead of pig iron; the covering material melts, rises with the slag, and allows the coke gradually to come in contact with the molten iron.—L. A. C.

Casting metal; Method of —. C. McKnight, jun., Sewickley, Pa. U.S. Pat. 1,331,816, 24.2.20. Appl., 20.12.19.

To reduce porosity and inclusions at or near the surfaces of cast ferrous alloys, the moulds are coated with a sufficient quantity of a material as will combine with the dissolved gases and metallic oxides in the molten metal without materially affecting the physical properties of the metal.—J. W. D.

Strain-hardened metals; Coated —. W. R. Whitney, Niskayuna, N.Y., Assignor to General Electric Co. U.S. Pat. 1,331,888, 24.2.20. Appl., 15.6.18.

FERROUS metals under strain are prevented from becoming brittle during treatment with a hydrogen-generating agent by coating them with a material impermeable to hydrogen.—J. W. D.

Sodium-lead alloy. W. Stockmeyer, Minden, and H. Hanemann, Charlottenburg. Ger. Pat. 304,244, 25.3.17.

THE alloy consists of lead and sodium with less than 0.5% Cu. For example, an alloy containing 1% Na and 0.2% Cu is more ductile than that containing no copper, and may be drawn hot without breaking.—A. R. P.

Autogenous cutting of metals; Process for the —. Deutsche Wildermann-Werke Chem. Fabr. G.m.b.H., and C. Waldeck, Lülsdorf. Ger. Pat. 307,179, 7.5.18.

THE metal is exposed to the action of a jet of chlorine or a mixture of chlorine and other suitable gases whereby volatile or water-soluble compounds of the metal are formed. Iron, zinc, aluminium, copper, and lead may be cut by the process, which is also suitable for use under water.—A. R. P.

Alloy. K. Hunger, Mülheim. Ger. Pat. 309,243, 6.1.18.

AN alloy suitable for use as bearing metal contains lead and about 5% of a mixture of two parts of zinc and one part of magnesium.—L. A. C.

Tin-plate scrap; Process for detinning —. Chem. Fabr. Buckau, Magdeburg. Ger. Pat. 309,277, 12.1.18.

THE operation is carried out by treating the scrap with undiluted chlorine at 300° C., and removing the vapour of tin tetrachloride from the reaction chamber as fast as it is formed. By this means attack of the iron is avoided.—A. R. P.

Tin; Process for recovering — from waste tin plate or the like. T. A. Eklund, Stockholm. Ger. Pat. 316,111, 20.3.19. Int. Conv., 1.2.19.

SCRAP tin or the like is treated with hydrochloric acid in the presence of an oxidising agent (an alkali nitrate), or tin sludge is dissolved in hydrochloric acid in the presence of an alkali nitrate, and the solution containing quadrivalent tin is used for detinning scrap tin plate, yielding a solution containing divalent tin. The solution obtained in either case is electrolysed, using a current of about 1 volt, an anode of carbon, block tin, or tinned iron, and a cathode of tin, iron, or other metal. Crystalline tin is deposited on the cathode, and the exhausted bath is re-oxidised and used for the treatment of more waste tin.—L. A. C.

Coating metals with lead; Process for —. Montag und Laube, Hannover-Linden. Ger. Pat. 310,176, 14.9.17.

THE metal is treated by the "contact" process to coat it with a thin film of lead which adheres tenaciously. Thicker coatings of lead are then readily deposited on this by electrolysis in the usual way.—A. R. P.

Metallic surfaces; Coating — with lead, tin, zinc, or alloys of the same. Berlin-Burger Eisenwerk A.-G., Berlin. Ger. Pat. 315,712, 17.12.18.

A THIN layer of the coating metal or alloy is first deposited on the metallic surface by electrolytic means, the article is then dipped in a molten bath of metal of the same composition, and is covered with a poor heat conductor to prevent rapid cooling. Iron surfaces are first treated with an acid, and then with a sand blast to remove carbon.—L. A. C.

Metal turnings; Production of briquettes from —. Magnet-Werk G.m.b.H. Eisenach, Eisenach. Ger. Pat. 315,989, 26.4.18.

METAL turnings or the like are compressed with simultaneous heating by means of an electric current.—L. A. C.

Copper baths; Revivifying electrolytic —. Hüttenwerk Niederschöneweide A.-G. vorm. J. F. Ginsberg, Berlin-Niederschöneweide. Ger. Pat. 316,048, 13.12.17.

COPPER anodes containing cuprous oxide, either alone, or with other anodes, are used in an electrolytic copper bath to avoid the necessity for adding copper sulphate to the bath.—L. A. C.

Graphite; Means for enclosing pieces of — in refractory metals. G. Ising and H. Borofski, Brunswick. Ger. Pat. 316,180, 3.10.18.

THE formation of metallic carbides on the addition of pieces of graphite to a molten metal, e.g., iron, to produce a metal having a surface with low friction, is prevented by first coating the graphite with copper or other suitable metal.—L. A. C.

Wrought iron; Mechanical puddling in the manufacture of —. H. Maplethorpe, West Bromwich. Eng. Pat. 139,359, 5.5.19. (Appl. 11,229/19.)

Iron and steel; Manufacture of —. H. B. Clapp, Wimbledon, Assignor to D. R. Blair, London. U.S. Pat. 1,330,846, 17.2.20. Appl., 23.12.18.

SEE Eng. Pat. 134,283 of 1918; this J., 1920, 28 A.

Zinc; Extraction of —. E. S. Berglund, Trollhättan, Assignor to S. Hult, Stockholm, Sweden. U.S. Pat. 1,331,740, 24.2.20. Appl., 12.9.18.

SEE Eng. Pat. 120,549 of 1918; this J., 1919, 467 A.

Open-hearth furnace. J. O. Griggs, Youngstown, Ohio. U.S. Pat. 1,331,989, 24.2.20. Appl., 2.6.19.
SEE Eng. Pat. 127,785 of 1918; this J., 1919, 540 A.

Brass borings, brass turnings, and like material; Separation and extraction of dust and iron from —. W. Sowden, Leeds. U.S. Pat. 1,332,078, 24.2.20. Appl., 20.7.17.
SEE Eng. Pat. 105,174 of 1916; this J., 1917, 556.

Alloys for thermo-couples. Ger. Pat. 306,359.

XL.—ELECTRO-CHEMISTRY.

PATENTS.

Storage cells; Electric —. C. J. V. Fery, Paris.
Eng. Pat. 124,211, 7.3.19. (Appl. 5706/19.)
Int. Conv., 30.4.17.

In secondary cells of the type in which the electrolyte is incorporated with an absorbent material such as sand, pumice powder, or the like, the negative element is located horizontally at the bottom of the containing vessel, and the positive element is placed vertically and above the negative element. The negative element may be formed by pouring on to the bottom of the containing vessel a paste of litharge and water acidulated with sulphuric acid and embedding therein a leaden wire which is bent to serve as one terminal of the cell. The positive electrode may consist of a leaden cylinder having ribs, between which the active material is introduced, a spirally wound leaden wire serving to retain this material in place. The device eliminates deformation of the positive electrode and prevents sulphating of the negative electrode on open circuit.—J. S. G. T.

Spongy-lead electrodes [for accumulators]; Manufacture of —. E. Noll, Frankfurt. Ger. Pat. 315,592, 17.11.15.

A mixture of a reducible lead compound and a reducing agent such as charcoal or sugar, especially the latter, is heated under pressure. For example, plates composed of a mixture of lead oxide and reducing agent are heated by immersion in a lead bath, and are then cooled without access of air by immersion in water. Plates so made possess a very uniformly porous structure.—J. S. G. T.

Paper for use as dielectric. Eng. Pat. 138,226.

XII.—FATS; OILS; WAXES.

Olive oil; Lipolytic enzymes in —. T. M. Rector.
J. Ind. Eng. Chem., 1920, 12, 156–158.

EMULSIONS of 50 c.c. of olive oil, 4 grms. of gum tragacanth, 2 c.c. of toluene, and 50 c.c. of water, were vigorously shaken and left for periods up to 30 days in a closed flask. In the case of unheated oil the acid value rose progressively from 0.7 to 3.6. The acid value of oil which had been heated to 75° C. rose to 22.8, and that of oil heated to 100° C. to 10.3, whilst after heating to 125°, 150°, and 175° C. the oil showed values of 5.3, 3.1, and 1.7 respectively. The lipolytic enzyme in filtered olive oil retains its activity for several years. The "foots" obtained in the purification of olive oil contains an anti-

hydrolytic enzyme. For example, the acid value of an olive oil, emulsified as described, increased to 8.8 in 25 days, whereas after the addition of unheated "foots" the acid value only rose to 1.4. The effect of this anti-enzyme is nullified by heat.
—C. A. M.

Pine-seed oil. O. von Friedrichs. Svensk Farm. Tidsskr., 1919, 23, 445, 461. Chem.-Zeit., 1920, 44, Rep., 67.

THE fatty oil from the seeds of *Pinus silvestris*, L. is a light, yellow, mobile, nearly odourless oil. A sample had the following characters.—Sp. gr. 0.9307; solidif. pt., -30° C.; $[n]_D^{15} = 1.4799$, $[n]_D^{40} = 1.4714$; acid value 0.92; saponif. value, 190.7; Hehner value, 94.75; Reichert-Meissl value, 0.79; and iodine value (Hanus), 159.2. The oil contained about 0.11% of volatile fatty acids, mainly butyric acid. There was 90.4% of non-volatile fatty acids, 7.5% glycerol, and 1.29% of crude phytosterol (m. pt. 135° C.). The fatty acids consisted of about 3% of solid fatty acids (palmitic acid, with 5% of stearic acid) and 97% of liquid acids (36.2% oleic, 56.2% linolic, and 7.6% linolenic acid).—C. A. M.

Fir-seed oil. O. von Friedrichs. Svensk Farm. Tidsskr., 1919, 23, 500. Chem.-Zeit., 1920, 44, Rep., 67.

THE fatty oil, as obtained by extraction with ether in Sweden from the seeds of *Picea abies*, Karst. (*Pinus abies*, L.) is a pale yellow mobile oil, with a somewhat bitter taste, recalling that of turpentine, and a faintly aromatic odour. A sample had the following characters:—Sp. gr. at 15° C. 0.9295; solidif. pt., -26 C.; $[n]_D^{15} = 1.4801$, $[n]_D^{40} = 1.4718$; acid value, 1.0; saponif. value, 191.8; iodine value (Hanus), 154; Hehner value, 92.65; and Reichert-Meissl value, 1.06. The oil contained 91.6% of non-volatile acids composed of 0.7% of palmitic acid and 99.3% of unsaturated acids (oleic 42.75, linolic 49.55, linolenic 7.7%). It also contained about 0.14% of butyric acid. The phytosterol had the characteristics of sitosterol.—C. A. M.

Marine animal oils; Reactions in the hydrogenation of —. T. Arentz. Tidsskr. for Kemi, 1919, 16, [11–13]. Chem.-Zeit., 1920, 44, Rep., 67.

THE solid fats obtained by the hydrogenation of marine animal oils do not show the same relationships between their physical and chemical constants as do natural fats. The refractive index and sp. gr. are both higher than the anticipated values. This is due to the formation of isomeric compounds of acids of the oleic series, which have a higher m. pt. The relative absorption of hydrogen was greater in the case of C_{16} – C_{18} glycerides than in that of C_{20} – C_{22} glycerides. When the hydrogenation is rapid the hardening process takes place in stages, and relatively unsaturated compounds are present in association with those completely saturated.

—C. A. M.

Yellow-tail fish oil. H. A. Gardner and A. Reilly. Circ. 86, Paint Manufacturers' Assoc., U.S.A., and Nat. Varnish Manufacturers' Assoc. Feb., 1920. 4 pp.

YELLOW-TAIL fish oil is obtained from the *Seriola dorsalis* which is abundant on the Southern and Lower Californian coast. The oil is cloudy, of light colour, faint odour, and unpleasant taste, and has the following characters: Iodine value (Hanus), 177 (filtered oil, 180); saponif. value, 190; acid value, 0.6; sp. gr. 0.9322. On exposure on a glass plate it dried in 105 hours to a fairly firm film as compared with 95 hours for raw linseed oil. With an addition of 10% of lead and manganese linoleate liquid drier it dried in 15 hours as compared with 12 hours for raw linseed oil prepared in the same manner. When mixed with an equal

weight of raw linseed oil, with and without drier, the drying results were about intermediate between those for the two oils separately.—A. de W.

Coconut oil and palm-kernel oil; Solubility of — in alcohol and acetic acid. J. R. N. van Kregten. *Ölten en Vetten*, 1919, 4, 185. *Chem. Zentr.*, 1920, 91, II., 203.

THE solubility of coconut oil and palm kernel oil in alcohol and acetic acid may be employed for estimating the composition of mixtures of these oils, but previous estimations lack uniformity, as fatty acids were not removed. In obtaining the results tabulated below the coconut oil contained 0.032% and the palm-kernel oil 0.060% of fatty acids, calculated on a mol. wt. of 200. Different experiments showed a divergence of only $\pm 1^\circ\text{C}$. The influence of water in the solvent on the critical temperature of solution is shown in the following table; 1 gm. of oil and 5 c.c. of the solvent were employed in each determination:—

Solvent.	Critical temperature of solution.			
	Sp. gr. at 15°/15°C.	Vol. %	Coconut oil.	Palm-kernel oil.
Alcohol ..	0.7942	99.06	20.2°C.	28.7°C.
	0.7981	99.10	30°C.	38.8°C.
	0.8001	98.75	35.5°C.	44.2°C.
	0.8020	98.36	39.5°C.	47.9°C.
Acetic acid. .	Sp. gr. at 15°/4°C.	% Acetic acid.		
	1.0573	99.25	17.9°C.	32.5°C.
	1.0579	99.05	26°C.	41.5°C.
	1.0581	98.85	30.9°C.	46.5°C.

The critical temperatures of solution of various mixtures of the two oils are also given.—L. A. C.

Saponification values [of oils and fats]; Influence of ester transposition in the determination of —. A. M. Pardee and E. E. Reid. *J. Ind. Eng. Chem.*, 1920, 12, 129—133.

TEST saponifications of benzyl formate, benzyl acetate, and methyl benzoate were made in the presence of various alcohols, a tube 1 m. long being used as reflux condenser. The results obtained with ethyl alcohol as medium confirmed Henriques' conclusion (this J., 1898, 673, 853), that in saponification there is transposition of esters, the loss being more pronounced with benzyl acetate, in which case ethyl acetate is formed and greatly increases the volatility, than with methyl benzoate, which yields ethyl benzoate and decreases the volatility. Hence low results may be expected when acetates are saponified in the presence of ethyl alcohol unless effective condensers are used. Inaccurate results are also obtained with isobutyl alcohol, methyl alcohol, or iso-amyl alcohol as medium. The best medium for saponification in general is normal butyl alcohol, which gave excellent results even with benzyl acetate.—C. A. M.

Oils; Action of nitric acid on saponifiable —. L. G. Radcliffe and C. Polychronis. *J. Soc. Dyers and Col.*, 1920, 36, 65—76.

THE action of nitric acid upon oils varies with the nature of the fatty acids which they contain. Saturated fatty acids, such as stearic acid, are but little affected by cold strong nitric acid or by fuming 99% acid, but are oxidised by hot nitric acid, with the formation of isonitrostearic acid and other compounds. Unsaturated fatty acids, such as oleic acid, react very slowly with strong nitric acid in the cold, but when treated with fuming nitric acid, even at a low temperature, yield nitrated products, while at the same time water is formed, probably through the nitration of the

hydroxyl group produced by the action of the nitric acid on the double linkage. Nitration of such acids as oleic acid lowers the iodine value (e.g., from 89.4 to 7), whilst the nitrated product has a definite hydroxyl value. Products free from nitrogen are never obtained by saponification. Nitrated oleic acid is probably a mixture of several substances containing NO_2 or NO groups. The action of nitric acid upon the glycerides of such unsaturated acids is probably of a similar character. Ordinary strong (72%) nitric acid has but little action upon such unsaturated glycerides. The nitration of castor oil, ricinoleic acid, and tricinolein proceeds in a similar manner, the hydroxyl groups forming nitric esters, while a nitrogen derivative is also formed of the nitro-oleic type. For the nitration of saponifiable oils at low temperatures nitric acid of sp. gr. 1.5 to 1.52 is required, although Brightman (this J., 1917, 985) has shown that under certain conditions castor oil can be readily nitrated by means of dilute nitric acid. The use of sulphuric acid with the nitric acid causes the reaction to be more energetic, but does not increase the amount of nitrogen in the products, which are much darker in colour. Sulphonated oils may be readily nitrated by boiling them with dilute (50—60%) nitric acid. Various fish oils contained from 3.19 to 3.43% of nitrogen after nitration, whilst nitrated whale oil contained 3.15% and had iodine value 15.6. Nitrated castor oil can dissolve an appreciable amount of nitric acid and still remain clear.—C. A. M.

PATENTS.

Oils; Method of hydrogenating —. G. Martin, Manchester. Eng. Pat. 139,239, 27.11.18. (Appl. 19,567/18.)

OIL, etc. is hydrogenated by a continuous process in an apparatus of the type described in Eng. Pat. 129,461/16 (this J., 1919, 645 A). A portion of the oil is preheated, while another portion is mixed in a second tank with a catalyst and then heated to the same temperature as the first portion. The oil from both tanks is mixed and introduced into a reservoir, whence it falls in a thin stream through a series of connected conduits, contained in a steam-heated chest, and encounters a current of hydrogen issuing from perforated pipes within each conduit. The unabsorbed hydrogen rises into the oil reservoir, whence it is pumped back into the gas reservoir, whilst the hydrogenated oil passes through a cooler, and is then forced through a filter by means of a pump.—C. A. M.

Catalyser for effecting hydrogenation and process of making same. Process for producing catalysers for hydrogenation. Process for hydrogenation. Process for producing catalysers and for effecting hydrogenation therewith. B. W. Elder, Los Angeles, Cal., Assignor to The Allbright-Nell Co. U.S. Pats. (A) 1,331,903, (B) 1,331,904, (C) 1,331,905, and (D) 1,331,906, 24.2.20. Appl., 7.6.18.

(A) Block nickel is rendered catalytically active by pulverising it by mechanical means in the presence of a protective liquid. (B) A practically inactive catalytic substance is converted into a highly active catalyst by converting it into a powder by a combined process of rubbing, squeezing, and percussive action. (C) Oil and hydrogen are brought into intimate contact at a suitable temperature with a finely powdered nickel catalyst produced by mechanical means from block nickel. (D) Oil is made to flow over catalytically active abraded nickel surfaces at a suitable temperature and in the presence of hydrogen.—C. A. M.

Lipase; Preparations containing —. R. Willstätter, Munich. Ger. Pat. 316,504, 5.9.18.

STABLE concentrated lipase preparations are obtained by absorbing lipase from an emulsion or suspension of the same by means of kieselguhr, kaolin, tale, barium sulphate, charcoal, or the like.

—L. A. C.

Glycerin from soap lyas; Process for obtaining —. R. Blum and C. Francke, Berlin. Ger. Pat. 310,045, 3.5.18.

SOAP lyas are concentrated by evaporation, and treated with ozone or ozonised air, whereby sulphur compounds are completely oxidised and rendered innocuous, whilst the fatty acids are converted into solid hydroxy-acids which can be readily separated. The ozone treatment may also be applied prior to acidification.—C. A. M.

Galls; Manufacture of stable preparations [detergents] from animal —. O. Lietz, Kiel. Ger. Pat. 315,352, 27.9.16.

ANIMAL galls are treated in ammoniacal or alkaline solution with hydrogen peroxide, with or without the addition of hypochlorites, and the active constituents are precipitated as a hard mass by the addition of acid. The product may either be employed as a washing powder in the solid form mixed with alkaline carbonates, or may be dissolved in alkalis or alkaline salts.—L. A. C.

Detergents; Manufacture of —. G. Bethmann, Frankfurt. Ger. Pat. 316,210, 8.9.17.

A SOLUTION of a zinc or cadmium salt is added to the solution obtained by decomposing glue by means of an alkali or alkaline-earth oxide or hydroxide or a dilute mineral acid. The product, evaporated to a thick liquid or to dryness, lathers well, and may be used as a soap substitute.—L. A. C.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Oil absorption of pigments. H. A. Gardner and R. E. Coleman. Circ. 85, Paint Manufacturers' Assoc., U.S.A., and Nat. Varnish Manufacturers' Assoc. Feb., 1920. 13 pp.

THE oil absorption of a pigment is defined as the amount of oil absorbed by unit weight of pigment when mixed together in a manner independent of mechanical forces or influences developed by actual grinding. The limit of absorption is characterised by that stage at which the surface of each pigment particle becomes thoroughly wetted by the liquid. In determining oil absorptions a medium must be chosen which has little effect in varying the degree of dispersity of the pigment. The air-dried pigment is well shaken in a wide-mouth stoppered bottle to eliminate packed particles, and 20 grms. is then weighed into a small jelly glass, 2½ in. diam. at the top and 3½ in. deep. Raw, well-settled linseed oil is then run on to the centre of the quantity of pigment, either drop by drop or 0.5 c.c. at a time, diminishing the rate of flow as absorption proceeds. The unmoistened portions of the pigment round the sides should be brought on to the oil by means of a stiff-bladed palette knife in order to ensure equal distribution. The small lumps that form should be equally distributed throughout the mass by stirring lightly without using pressure. Oil is then dropped on to the formed balls or lumps of paste and not on to the dry pigment. The end point is judged by the disappearance of all dry pigment and by the paste lump becoming softer and smearing the sides and bottom of the glass on stirring round. The tem-

perature of the ingredients should be maintained at 70°–100° F. (21°–38° C.). The result is returned as c.c. of oil per 100 grms. pigment. The oil absorptions of several common pigments are given. On the basis of the figures obtained the authors state that when similar amounts of thinners are added to pastes derived from unit weights of different pigments, paints of similar consistencies are obtained. (Cf. de Waele, Proc. Oil and Colour Chemists' Assoc., II., 13, 115–118; this J., 1919, 395 R.)

—A. de W.

Ultramarine; Studies on the constitution of —. L. Bock. Z. angew. Chem., 1920, 24, 23–24. (See also this J., 1915, 561.)

FURTHER evidence of the relationship between ultramarines and aluminate-silicates (zeolites) is brought forward. In the ultramarines the sulphur compounds take the place of the combined water in the zeolites. Experiments on the action of ammoniacal silver chloride solution on artificial ultramarines indicate that the silica-rich sulphur-rich and silica-poor sulphur-rich ultramarine blues are definite compounds of formulae, $2(\text{Na}_2\text{O}, \text{Al}_2\text{O}_3, 3\text{SiO}_2)\text{Na}_2\text{S}_4$ and $3(\text{Na}_2\text{O}, \text{Al}_2\text{O}_3, 2\text{SiO}_2)\text{Na}_2\text{S}_4$ respectively. A table is given showing the known ultramarines and their relationship to natural and artificial silicates.—J. K.

Bauxite as a pigment. A. Cobenzl. Farben-Zeit., 1919, 25, 20. Chem. Zentr., 1920, 91, II., 86.

THE blue colour of bauxite is due to ferrous sulphide in an easily oxidisable colloidal form, and the aluminium hydroxide itself takes no part in the production of the colour. A similar colour may be observed in barium sulphate that has stood for a long time in moist packages. In this case the organic matter in the water has reduced a little sulphate to sulphide, which has then been attacked by the acid present in the sample, and the liberated hydrogen sulphide has reacted with the iron compounds present with the production of colloidal ferrous sulphide.—A. R. P.

Bauxite as a pigment. M. Ragg. Farben-Zeit., 1919, 25, 151. Chem. Zentr., 1920, 91, II., 86.

THE author agrees with Cobenzl (see preceding abstract), that the blue colour of bauxite is due to colloidal ferrous sulphide. The occurrence of blue bauxite indicates that the mineral is composed of the residues from the solution of aluminous limestones which have become mixed with organic material of animal and vegetable origin. The decomposition of the latter has then produced the hydrogen sulphide required for the production of the blue colour.—A. R. P.

Varnishes and boiled oils; Determining the acid value of —. H. A. Gardner and R. E. Coleman. Circ. 87, Paint Manufacturers' Assoc., U.S.A., and Nat. Varnish Manufacturers' Assoc. Feb., 1920. 9 pp.

ACID values of oils or varnish media containing colloidally dispersed phases cannot be determined by the usual method of solution in alcohol and titration with dilute alkali, as the end point is indefinite owing to absorption of the alkaline base by the disperse phase. By using a neutralised mixture of equal volumes of purified 90% benzol and denatured alcohol as solvent the colloidally dispersed phase is brought into molecular solution, and can then be titrated as usual. Uncertainty of end point may be overcome by allowing to stand one or two minutes and observing the upper layer of oil and solvent, which at neutralisation should be clear and faintly pink.—A. de W.

Dopes for aeroplanes. Fuchs. See V.

Yellow-tail fish oil. Gardner and Reilly. See XII.

PATENTS.

Coumarone resin soluble in alcohol; Method for producing a —. Rütgerswerko A.-G., Berlin. Ger. Pat. 302,543, 9.6.17.

CAUDE solvent naphtha or heavy benzol, without previous removal of the bases or phenols or after removal of the bases, and with or without the addition of phenols, is subjected to polymerisation by the action of sulphuric acid or of sulphonic acids; on account of the presence of phenols the coumarone resin obtained in the usual way by subsequent distillation is soluble in alcohol and therefore suitable for the preparation of varnishes.—D. F. T.

Resin; Production of — from wood containing the same. Aktiebolaget Cellulosa, Stockholm. Ger. Pat. 315,731, 20.5.16. Int. Conv., 26.4.16.

WOOD rich in resin, such as Swedish pine, is heated under pressure with sufficient concentrated alkali solution, with the addition of a soluble neutral salt such as sodium chloride, to dissolve the wood and convert the resin into the alkali salts of the resin acids. Fatty acids and lignin precipitated together with the resin are soluble in alcohol and resemble resin in their properties, and thus have no deleterious effect upon the product. Oil of turpentine, methyl alcohol, ammonia, and amines distil over if the vapour is allowed to escape during the heating.—L. A. C.

Dope or substitute for celluloid, vulcanite, and the like. W. T. Robinson-Bindley and A. W. Weller, London. U.S. Pat. 1,331,127, 17.2.20. Appl., 20.2.19.

SEE Eng. Pat. 134,565 of 1918; this J., 1920, 14 A.

Terpenes etc. from defecation sludge. Ger. Pat. 316,503. See IIb.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchoucs; Scientific principles for the recognition of artificial — in technical rubber analysis. C. Harries. Gummi-Zeit., 1919, 33, 222—223. Chem. Zentr., 1920, 91, II., 143.

THE rubber is swollen in ten times its quantity of chloroform and then treated with 5.5—6% ozono until a sample no longer decolorises bromine; the solution is cautiously evaporated below 20° C. in a vacuum, and after drying in a vacuum for several days the ozonide is decomposed by boiling for an hour with twelve times its weight of water. Ozonides of caoutchoucs derived from isoprene and dimethylbutadiene decompose fairly smoothly with very little resin formation. A little of the filtered solution is treated with a few drops of ammonia solution, then acidified with acetic acid and boiled, when, except in the case of abnormal sodium caoutchoucs, the vapours show Knorr's pyrrole reaction and redden a pine shaving which has been wetted with hydrochloric acid. Ordinary Elberfeld isoprene caoutchouc yields 46% levulinic aldehyde and 60% levulinic acid together with formic acid and a little acetylacetone. The sodium-carbon dioxide isoprene-caoutchouc of the Badische Co. behaves similarly but more easily yields acetylacetone and succinic acid. The estimation of the various decomposition products is effected in the manner which has been described earlier. "Normal" dimethylbutadiene-caoutchouc yields acetylacetone almost quantitatively. The most difficult estimation is that of butadiene-caoutchouc; this yields only succinic dialdehyde, the phenylhydrazone of which is unstable but is readily converted by dilute hydrochloric acid into a white polymeric base melting at 184°—185° C. Vulcanised rubbers should be first extracted with acetone and then ozonised in the pre-

sence of calcium carbonate; in this way the resulting aldehydes and ketones are preserved from resinification, whilst the sulphuric acid and the organic acids are found in combination with calcium.—D. F. T.

Synthetic caoutchouc; Analytical estimation of —. G. Hubener. Gummi-Zeit., 1919, 33, 361—362. Chem.-Zentr., 1920, 91, II., 143—144.

"METHYL-RUBBER," whether raw or lightly vulcanised, undergoes bromination slowly and yields a product containing a higher proportion of bromine than that expected for a tetrabromide. Extraction of the bromide with carbon bisulphide and titration of the insoluble portion showed that raw and lightly vulcanised methyl-rubber on bromination yield a tetrabromide $C_{11}H_{16}Br_4$ and a bimolecular proportion of methyl bromide; hard vulcanised methyl-rubber gives no methyl bromide.—D. F. T.

Rubber goods and reclaimed rubbers; Rapid determination of "golden antimony" (antimony sulphide) in —. W. C. Schmitz. Gummi-Zeit., 1918, 33, 2—3. Chem.-Zentr., 1920, 91, II., 144—145.

TWO grams of the material is heated with 45 c.c. of sulphuric acid in a 300 c.c. Kjeldahl flask for 20 min.; the cooled solution is then treated with 3 grms. of ammonium persulphate and gently reheated for 10—15 min. longer after it has become colourless. The cooled liquid is diluted, almost neutralised with ammonia regardless of any precipitate, feebly acidified with hydrochloric acid, and then saturated with hydrogen sulphide. The precipitate is dissolved in hydrochloric acid containing tartaric acid, and the filtrate, after expulsion of the hydrogen sulphide, is titrated with potassium bromate using methyl orange as indicator. If the original material contains no iron the precipitation can be omitted; the colourless solution in sulphuric acid is heated for 20 min. with 5 grms. of potassium sulphate; a little potassium metabisulphite is introduced and the sulphur dioxide expelled by boiling; after repeating this operation twice more the liquid is diluted with 40 c.c. of water, and 10 c.c. of hydrochloric acid and a considerable quantity of tartaric acid added; titration is then effected as in the earlier process. The whole estimation needs 2—4 hours.—D. F. T.

PATENTS.

Rubber; Process for regenerating vulcanised —. S. van Raap, Amsterdam, Holland. Eng. Pat. 122,188, 3.1.19. (Appl. 227/19.) Int. Conv., 8.1.18.

GROUND waste rubber is dissolved with the aid of mechanical treatment at 150° C. in the smallest possible amount of an oil, such as linseed oil or castor oil, which is capable of combining with sulphur; the mixture is then heated at 160°—170° C. with sufficient sulphur and for a sufficient time to convert the oil into a solid mass; after having been rolled this is subjected to further treatment, with or without the addition of new rubber, and is finally vulcanised.—D. F. T.

Rubber and other heavy plastic material; Machine for treating —. Machines for kneading or mixing rubber and other heavy plastic material. F. H. Banbury, Ansonia, Conn., U.S.A. Eng. Pats. 119,241 and 119,242, 17.9.18. (Appls. 15,085 and 15,086/18.) Int. Conv., 21.3.17 and 18.11.16.

XV.—LEATHER; BONE; HORN; GLUE.

[Tannery] lime liquors; Analysis of —. Report of committee of Soc. of Leather Trades' Chem. D. Burton. J. Soc. Leather Trades' Chem., 1920, 4, 32—41.

DEFLATION, swelling, solvent action on the

epidermis, interfibrillary substance and the true hide substance, and removal of the fat are the effects generally desired in the process of liming. The depilatory properties of a lime liquor can be improved by addition of sulphides which are represented by the amount of $N/10$ $ZnSO_4$ solution required per 100 c.c. of lime liquor, giving the figure s . The swelling depends on the alkalinity and the content of soda and salt. The total alkalinity a is determined by Bennett's method (this J., 1916, 479), and includes that derived from calcium hydroxide, sodium hydroxide, sodium hydrosulphide, ammonia, and lime in combination with the weakly acid decomposition products of the hide and epidermis. The swelling increases with the caustic alkalinity due to $NaOH$ and $Ca(OH)_2$, which can be determined by titrating 100 c.c. of the filtered lime liquor with $N/10$ HCl with phenolphthalein as indicator. Sodium hydrosulphide ($\frac{1}{2} s$) has no swelling action, but ammonia (c.c. $N/10$ HCl per 100 c.c. of lime liquor = m) has a slight swelling effect. Lime in combination with weak acids, $a - (c + \frac{1}{2}s + m)$, depresses the ionisation and also the solubility of the lime and consequently the swelling. Sodium hydroxide is included in the alkalinity, but it and the salt can be determined by Bennett's method (*loc cit.*) Salt is stated to depress the swelling. The solvent action of lime liquors depends on the acid products from the epidermal matter and dissolved hide substance, the amino-acids present, free ammonia, total nitrogen, and the bacteria present. The difference in the titration figures with acid, using phenolphthalein and methyl orange as indicators, is a measure of the acid products. The amino-acids are determined by Stiasny's method (this J., 1910, 771) and the total nitrogen by the Kjeldahl method. Plate cultures from a lime liquor on a slightly alkaline peptone gelatin give a measure of the gelatin-liquefying bacteria. It is necessary to adopt a definite method of filtration which will give a constant degree of clearness. The degree of hydrolysis is $100(178-a)/174$ where $a=2.8 K/\nu$, K being the Kjeldahl figure and ν the no. of c.c. of $N/10$ $NaOH$ per 50 c.c. of lime liquor in the Stiasny amino-acid determination. A list of the principal references to the modes of action and methods of analysis of lime liquors is given.—D. W.

PATENTS.

Liming and dehairing hides; Process of —. P. Remer, Milwaukee, Wis., Assignor to A. G. Wackenreuter and W. S. Shaw, Chicago, Ill. U.S. Pat. 1,331,723, 24.2.20. Appl., 14.6.18.

HIDES are first soaked in a weak lime liquor containing a moderate amount of sodium sulphide, then washed, and soaked in a materially stronger solution of lime unmixd with sodium sulphide.—D. W.

Condensation products [tanning materials] from formaldehyde and aromatic derivatives; Manufacture of —. A. G. Bloxham, London. From Durand & Huguenin S. A., Basle, Switzerland. Eng. Pat. 138,796, 27.5.19. (Appl. 13,356/19.)

TANNING materials are prepared by condensing a 1- or 2-aminonaphthalenemono- or disulphonic acid, or a mixture of the same, and an aromatic hydroxy compound which contains not more than one hydroxyl group to each nucleus and one or more salt-forming acid groups, with formaldehyde, or a substance which develops formaldehyde, in dilute solution, at 60° – 80° C. in the presence of a little sulphuric acid. The clear liquor obtained is neutralised with sodium carbonate and/or a hydroxide of a metal, the salts of which have a tanning action, e.g., chromium, aluminium, or iron.—L. A. C.

XVI.—SOILS; FERTILISERS.

Soil and its water content; Relations existing between the —. B. A. Keen. J. Agri. Sci., 1920, 10, 44–71.

A RESUME is given of investigations on moisture in soil and its behaviour under varying conditions. The subjects dealt with are the maximum water capacity and pore space, the permeability, the capillary effects and the water-retaining capacity, the capillary movement of soil water, the hygroscopic moisture, and the surface forces. The last subject is dealt with from the point of view of the colloidal hypothesis, and it is considered that one of the most important soil constituents is the colloidal clay, as it is associated with a small amount of pore space which modifies the movement of water in the soil interstices over a wide range of moisture content. A change in the moisture content is reflected in a change in the soil solution. Conclusions based on an examination of soil solution after it has been removed from the soil are open to doubt. The system, soil plus soil solution, must be treated as a whole.—J. H. J.

Nitrates; Washing out of — by drainage water from uncropped and unmanured land. E. J. Russell and E. H. Richards. J. Agric. Sci., 1920, 10, 22–43.

AN account is given of the results from three natural soil gauges in operation at Rothamsted since 1870. The soil received no manure, and was kept free from weeds. All the drainage water was collected, measured, and analysed. During the whole period there was a continuous, though remarkably slow, loss of nitrate from the soil. Originally the soil contained 3500 lb. of nitrogen per acre in the top 9 in.; in 1917 this had been reduced to 2380 lb., and the drainage water had carried away 40 lb. of nitrogen per acre per annum. All the nitrogen removed from the soil appeared as nitrate in the drainage water. The amount of nitrogen removed at any time varied with the rainfall, a high rainfall removing higher amounts of nitrate. On the average 1 in. of rain removed 1 lb. of nitrogen per acre. The slowness of the removal of nitrogen may be attributed to the ammonia and nitrate formed as a result of the decomposition of the organic matter being possibly assimilated by organisms, such as algae, fungi, bacteria, and that only on the death of these organisms is part of the nitrogen finally given out and part re-assimilated. The reliability of the results is shown by the fact that the total of the chlorine in the rain-water during the whole period agreed with the total of the chlorine in the drainage water.—J. H. J.

Ammonia in soil; Determination of —. D. J. Matthews. J. Agric. Sci., 1920, 10, 72–85.

DETERMINATIONS of ammonia in soil were made by the aeration method. The apparatus used consisted of a long, wide, aeration tube placed in a sloping position, the lower end being closed with a cork carrying the air inlet tube, and the upper end connected to the bottom of an absorbing apparatus, consisting of an upright tube with two bulbs and with a splash retainer in its upper end. 25 gms. of soil is placed in the lower part of the aerator, and 50 c.c. of a solution of sodium carbonate and chloride and 1 c.c. of paraffin are added. $N/50$ sulphuric acid and a few drops of methyl red are placed in the absorber, and a current of air washed through acid is drawn through the apparatus at the rate of 300 litres per hour for 6 hours. With most soils the efficiency of the apparatus was found to be over 98%. With soils containing much unstable organic matter, such as heavily-manured glass-house soils, it was found better to replace the

usual alkaline solution by a solution of magnesia in strong sodium chloride and to aerate for a fixed period of 3 hours. With soils rich in chalk, low results were always obtained unless the samples were very finely ground.—J. H. J.

PATENT.

Phosphoric acid from superphosphate manufacture: Utilisation of — in the saccharification of cellulose. F. L. Schmidt, Stolberg, and Chem. Fabr. Rhenania, Aachen. Ger. Pat. 304,400, 11.7.17.

PHOSPHATES are treated with a small excess of sulphuric acid so as to produce phosphoric acid instead of superphosphate; this phosphoric acid is employed for the saccharification of cellulose, and is then precipitated in the form of a high-grade fertiliser by the addition of lime or chalk.—J. F. B.

XVII.—SUGARS; STARCHES; GUMS.

Milk sugar [lactose] from whey; Extraction of —. H. E. Woodman. J. Agric. Sci., 1920, 10, 1—11.

EXPERIMENTS were made on the possibility of improving the method of extraction of lactose from whey. In the German method the whey is nearly neutralised with caustic soda, evaporated *in vacuo* at 60°–70° C. to a tenth of its volume, and allowed to cool. The sugar crystallises out and is separated by the centrifuge. The mother liquor is boiled, the precipitated protein filtered off, and the filtrate allowed to crystallise. A recovery of 75% of the sugar (3.85% on the whey) is obtained. By removing the protein by heating at 93° C. before evaporating, clarifying the filtrate with alumina cream, evaporating, and treating with charcoal and magnesium and calcium sulphates, a yield of 32% of lactose (on the whey) was obtained, containing 1.5% each of protein and ash, a greater degree of purity than by other methods. It was found that an extremely small amount of iron was dissolved from the vacuum pan during evaporation.—J. H. J.

Invertase; Detection of — in the pure honey of bees. A. Caillas. Comptes rend., 1920, 170, 589—592.

INVERTASE has been isolated, as its aqueous solution, from a sample of honey, and characterised, particularly in so far as its action on sucrose is concerned.—W. G.

PATENTS.

Adhesive compositions; Improving —. M. Sarason, Berlin. Ger. Pat. 316,080, 2.7.18.

ADHESIVE compositions from water-glass, sulphite-cellulose waste lyes, or the like, are improved by the addition of a small quantity of liquorice extract or glycyrrhizin.—L. A. C.

Adhesive; Manufacture of an — from sulphite-cellulose waste liquor. K. Hüttenes, Düsseldorf. Ger. Pat. 316,234, 14.2.18.

LEAD acetate is added to sulphite-cellulose waste liquor, and the solution is evaporated.—L. A. C.

XVIII.—FERMENTATION INDUSTRIES.

Enzymes. III. Invertase and other enzymes of germinated barley. D. Maestrini. Atti R. Accad. Lincei, 1919, [V.], 28, ii., 509—511. (Cf. this J., 1920, 244A.)

INVERTASE can be extracted from germinated barley dried at temperatures below 40° C. by 0.003 mol. % acetic or hydrochloric acid solution, and is present, not only in the emulsion, but also in the filtrate of the extract. To obtain an active liquid, the extraction should last at least six hours at 30°–35° C.; the enzyme acts best at about 50° C. and is destroyed at 55° C. The activity of malt invertase is destroyed in 48 hours by 0.003 mol. % potassium hydroxide solution. Germinated barley contains a catalase and an oxydase, but no maltase, lactase, or rennase; the extract does, indeed, coagulate milk, but such coagulation is due to the acidity of the extract, as it is produced even after the latter has been boiled.—T. H. P.

Fermentation; Action of copper on alcoholic —. K. Schweizer. Bull. Assoc. Chim. Sucr., 1919, 37, 160—173.

IN comparative experiments on the fermentation of sucrose solutions by yeast, in glass and copper vessels, fermentation ceased in the copper vessels when less than half of the sugar had been decomposed. The inhibitive influence of the metal was not prevented by previously cleaning it with sand or by conducting the fermentation in presence of calcium carbonate to neutralise the acids produced. A 6% brewery wort and a 24% laboratory malt wort fermented as well in copper vessels as in glass ones; only in the case of a very light laboratory wort was any unfavourable effect of the copper observed, and this was not very marked. It is probable that in ordinary worts the proteins protect the yeast from the toxic action of traces of dissolved copper by combining with the latter themselves. Copper (coins) previously cleansed by immersion in nitric acid exerted no inhibitive action on the fermentation of sucrose solution in experiments extending over two days. In further experiments it was found that cupric oxide added to fermenting sugar solutions has no adverse effect, but cuprous oxide has a powerful inhibitive action. Quantities of cuprous oxide larger than 0.013 gm. per 0.5 gm. of pressed yeast entirely prevented fermentation, whilst quantities less than 0.1 mgm. per 0.5 gm. of yeast had no inhibitive action.—J. H. L.

Wine making; Applications of the reducing action of yeast in —. Matthieu. Bull. Assoc. Chim. Sucr., 1919, 37, 174—175.

THE method of treating the yellow malady of wines by re-fermentation depends, for its effect, on the reducing action of the yeast on the oxidation products which are responsible for the colour, flavour, and aroma characteristic of the malady. Bitterness in wines may be partially or entirely eliminated by similar treatment, or simply by mixing the wines with active yeast. The "cooked" flavour acquired by musts when heated, *e.g.*, for the purpose of concentration or pasteurisation, disappears again during the fermentation. Bitterness or "cooked" flavour in red wines may be effectively treated by means of active yeast, but the colour is diminished at the same time owing to adsorption by the yeast. The practice of improving "flat" wines by contact with marc from the presses depends to some extent on the reducing action of the yeasts of the marc, but other factors, such as admixture with the new wine contained in the marc, also play a part; the benefit of this treatment is often lost if the regenerated wine is afterwards exposed to the air. Another application of the reducing action of yeast

consists in the preservation of the characters of young wine in wines kept in contact with active yeast; the presence of the yeast tends to prevent the formation of oxidation products which would confer the characters of old wines.—J. H. L.

XIXA.—FOODS.

Milk; Differentiation between poor and adulterated —. T. R. Hodgson. Analyst, 1920, 45, 91—94.

THE author has applied the formulæ given by Lythgoe (this J., 1914, 1166) to a large number of samples of milk, and finds that the formulæ are untrustworthy for the purpose of distinguishing between poor and adulterated milk. For instance, a milk containing 0.30% of fat and 7.31% of solids-not-fat, and admittedly skimmed, gave results by the formulæ indicating that it was "poor but genuine."—W. P. S.

Cheeses; New method of testing —. A. Geake. J. Agric. Sci., 1920, 10, 86—89.

AN attempt was made to estimate the degree of ripeness of a cheese from the extent of proteolysis as measured by the amino-nitrogen. Sørensen's method of determining amino-nitrogen was applied as follows:—8 grms. of cheese is ground three times with 30 c.c. of acetone and the residue allowed to dry in the air. 3 grms. of this residue is shaken with 50 c.c. of N/10 potassium hydroxide for 1 hr., and the mixture is filtered. 20 c.c. of the filtrate is titrated to neutrality with N/10 sulphuric acid, using phenolphthalein as indicator. 10 c.c. of neutral formaldehyde solution is then added, and the solution titrated back as usual. The total nitrogen is determined in 5 c.c. of the cheese solution by Kjeldahl's method. The result is returned as percentage of amino-nitrogen in total nitrogen. The method was tested on various cheeses of known quality, and a comparison is made between the figures obtained and the quality expressed in commercial terms.—J. H. J.

Marine algæ; Utilisation of — as foods. P. Gloess. Monit. Scient., 1920, 64, 3—5.

CERTAIN seaweeds (*Fucaceæ*, *Laminariaceæ*), after proper treatment for the removal of salts, form a valuable food or fodder; potassium salts and iodine may be recovered from the extracted salts.

PATENTS.

Foodstuffs; Manufacture of —. H. Bollmann, Hamburg, Germany. Eng. Pat. 109,265, 27.8.17. (Appl. 12,297/17.)

OIL-CONTAINING seeds, yeast, dried fish, etc., are extracted with a mixture of 120 parts of carbon tetrachloride and 80 parts of 96% alcohol with the aid of heat. Fat, fatty acids, and bitter principles are thus removed, and the residue after removing the solvent is in a state suitable for use as a food-stuff.—J. H. J.

Refrigeration of fish and other foods. N. Dahl, Trondhjem, Norway. Eng. Pat. 138,788, 13.5.19. (Appl. 11,965/19.)

FISH are packed in containers to which a refrigerating liquid is admitted at the bottom and passes upwards through the mass of fish. The rate of passage of the liquid can be controlled so as to prevent the fish becoming compressed at the bottom of the container. The liquid overflows at the top of the container and is collected, re-cooled, and used again. The process is conducted in the open air. (Reference is directed to Eng. Pat. 125,076; this J., 1919, 788 A.)—J. H. J.

Materials [foodstuffs] subject to putrefaction or decay; Methods for preserving — and apparatus therefor. R. Pape, Bussum, Holland. Eng. Pat. 139,100, 21.7.19. (Appl. 18,140/19.)

THE substance is placed in a double-walled chamber, and the development of bacteria is prevented by "suppressing the negative electric field and negative electric earth field by superposing an artificial electric field on the electrical earth field and in an opposite direction thereto," or by passing moist air into the chamber which is insulated from the earth, the air being first passed over moist layers (the moistened walls of the chamber) or over metallic conductors.—W. P. S.

Chocolate and other materials; Cooling chambers for —. E. C. R. Marks, London. From Fours et Proc. Mathy, Liège, Belgium. Eng. Pat. 139,383, 6.6.19. (Appl. 14,442/19.)

AN endless band conveys the material through a chamber; cold air flows through the latter, passing first over the upper stretch of the band and returning either through the space between the upper and lower parts of the band or beneath the lower part of the band. The spaces in the chamber may be formed by the band itself. The air leaving the chamber may be dried, compressed, and delivered into a cooler mounted near the upper part of the chamber.—W. P. S.

Flour; Process of bleaching and improving —. E. T. Fegan, Minneapolis, Minn., Assignor to A. R. Sasse, Kansas City, Mo. U.S. Pat. 1,330,937, 17.2.20. Appl., 18.3.18.

FLOUR is subjected to the action of gaseous chlorine and ammonia under such conditions that a "precipitate of ammonium chloride" is formed.

—W. P. S.

Bran and similar products; Process of extracting —. L. C. Reese, Saginaw, Mich. U.S. Pat. 1,331,125, 17.2.20. Appl., 19.3.18.

BRAN is treated in a series of extractors with an aqueous medium at a temperature most favourable for the conversion of the starch into sugars and at which the albumin is not coagulated; the exhausted material from this first series is then extracted in a second series with boiling water, the hot extract obtained being cooled to the temperature of the liquid in the first series of extractors on its passage to the latter.—W. P. S.

Foods or other substances; Process of heat-treating — N. H. Fooks, Mount Airy, Md. U.S. Pat. 1,331,337, 17.2.20. Appl., 29.10.19.

A liquid is heated under pressure to a temperature above its boiling point, and the substance to be treated is fed continuously into the vessel containing the liquid, passing first through the gas space above the liquid, then into the liquid, and on emerging from the latter is discharged from the vessel.—W. P. S.

Cellulosic material; Saccharification of — with gaseous hydrochloric acid. Chem. Fabr. Rhénania A.-G., Aachen, F. L. Schmidt and G. A. Voerkelius, Stolberg. Ger. Pat. 301,399, 8.5.17.

THE material is first moistened with cold highly concentrated (40%) hydrochloric acid and then treated with gaseous hydrogen chloride. Example: 400 kilos. of sawdust is uniformly moistened with 400 litres of 40% hydrochloric acid and, after steeping for a short time, the mass is saturated with the acid gas. The acid is allowed to act upon the wood for about 6 hours, and is then drawn off by suction. If the residual acid be neutralised with lime or soda the product is directly available for use as a feeding material in which the whole of the cellulose of the wood is present in the form of sugar or dextrin. If it be desired to convert the dextrin into fermentable sugar the product of the reaction must be lixiviated and the solution heated for 2 hours at 120° C.

—J. F. B.

Potatoes; Preservation of —. Verein der Spiritus-Fabrikanten in Deutschland, Berlin. Ger. Pat. 315,853, 5.1.17.

A MIXTURE of finely-shredded potatoes and sufficient dry pulp, straw meal, or the like, to absorb the water in the potatoes, with or without the addition of molasses, yeast, or the like, is compressed by a pressure up to about 200 atm.—L. A. C.

Saccharification of cellulose. Ger. Pat. 304,400. See XVI.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Determination of the rate of solution of atmospheric nitrogen and oxygen by —. Part II. W. E. Adeney and H. G. Becker. Sci. Proc. Royal Dublin Soc., 1919, 15, 609–628. (See also this J., 1919, 156 A.)

DETAILS of further experiments are given, together with formulæ by means of which the rates of solution of oxygen, nitrogen, and air in water may be calculated for any conditions of area exposed, depth, or initial degree of saturation, provided the water is kept uniformly mixed.—W. E. F. P.

Boiler feed water; Removal of dissolved gases from —. L. Jung. Stahl u. Eisen, 1920, 40, 321–326.

IN considering the suitability of feed waters the content of dissolved oxygen and carbon dioxide should not be overlooked (cf. Cobb and Dougill; this J., 1914, 403). A test is described in which polished iron plates were suspended in samples of water boiled in a small apparatus for several hours. The degree of corrosion was determined by the loss in weight and by microscopic examination. A condensed water from a turbine, although containing only 3.23 c.c. of oxygen per litre, was corrosive because, owing to the softness of the water, no protective coating of scale was formed. Although this water when condensed was practically free from

oxygen, tests showed that it had very readily taken up a further quantity. This emphasises the necessity for preserving such water in closed vessels prior to feeding again to the boilers. A sample of condenser water containing 5.0 c.c. oxygen per litre freed from oil by electrical treatment was the most corrosive of four samples examined, especially when mixed with fresh water from the public supply which contained 7.0 c.c. of oxygen per litre. A condenser water carefully maintained free from oxygen to which the test was applied for 13 hrs. showed scarcely any attack on the metal. Dissolved oxygen should be removed from a boiler feed when possible. Chemical methods such as a preliminary treatment with iron turnings are unsatisfactory. A preliminary heating followed by collection of the gases may be effective. Mechanical methods involving agitation under reduced pressure are effective in large-scale continuous work. In every case treated water should be stored in vessels out of contact with air, and the same precaution should be taken with condenser water which may be quite satisfactory when first collected.—H. J. H.

Refuse destruction; Economics of —. P. M. Grempe. Feuerungstech., 1920, 8, 86–87.

IN consequence of the shortage of some of the principal building materials during the war, experiments have been made in Germany with the clinkers produced by the destruction of refuse in municipal incinerators. Particularly successful results were obtained in the town of Fürth, in Bavaria. The clinkers from the incinerators contained 55.6% SiO₂, 11.7% Fe₂O₃, and 13.9% Al₂O₃. Of the 55.56% SiO₂, 2.15% is soluble in soda solution, and 3.11% (together with 1.80% Al₂O₃) soluble in 30% potash solution, showing the presence of hydraulic silicates. The clinker inhibits rusting, and therefore is suitable as an aggregate for reinforced concrete. The clinkers have been used for the manufacture of paving stones, kerb-stones for pavements, covers for cable-conduits, etc. In tests with concrete prepared from mixtures of cement, sand, and clinker in the proportions 1:2:4, 1:3:6, and 1:4:8, the crushing strength after keeping for the periods mentioned, in a moist condition, were respectively: 28 days, 232, 139, and 55.6 kilos. per sq. cm.; 90 days, 288, 171, and 71.2; 1 year, 322, 190, and 94.0 kilos. per sq. cm.—A. G.

PATENTS.

Sewage; Process of treating —. J. W. Wilson, San Diego, Cal. U.S. Pat. 1,331,735, 24.2.20. Appl., 4.12.16.

IN the treatment of a sewage comprising septic and antiseptic portions, the two portions are kept separate, and the septic portion is retarded in flow to permit of the solids breaking down. When this has been effected the sewage is introduced into a liquefying tank. After liquefaction is completed, the liquid is run out and added to the antiseptic portion of the sewage.—J. H. J.

Liquids; Process and apparatus for sterilisation or pasteurisation of —. A. Mulertz, Frederiksberg, Denmark. Eng. Pat. 132,237, 6.8.19. (Appl. 19,425/19.) Int. Conv., 31.8.18.

THE liquid is passed upwards through narrow vertical tubes surrounded by a steam jacket, and then downwards through a similar series of tubes provided with a cold-water jacket. The exit for the liquid is fitted with a counter-pressure valve which may be so adjusted that the liquid does not boil during the treatment.—W. P. S.

Separating liquids. Eng. Pat. 135,655. See I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Quinine salts; Detection of other alkaloids in —. I. M. Kolthoff. Pharm. Weekblad, 1919, 56, 451—459.

KERNER and Weller's method is not sufficiently accurate under all conditions, and has many disadvantages. The author has devised a test which is suitable for quinine sulphate but not applicable to other salts. The nitroprusside test is not considered to be sufficiently sensitive. The most accurate test for all quinine salts is De Vrij's chromate test, for the application of which to quinine bisulphate and quinine a few preparatory details are given. (See also J. Chem. Soc., 1920, ii., 203.)

—W. J. W.

Aribin; Identity of — with harman. E. Späth. Monatsh., 1919, 40, 351—359.

A COMPARISON of aribin, its hydrochloride, its aurichloride, its chloroplatinate, and its picrate showed their identity with harman and its derivatives. (See further J. Chem. Soc., 1920, i., 327.)

—J. K.

Scabiosin, a new glucoside hydrolysed by emulsin. E. Bourquelot and M. Bridel. Comptes rend., 1920, 170, 486—491.

FROM the roots of *Scabiosa succisa*, L. the authors have isolated, in addition to sucrose, a new glucoside, scabiosin, which on hydrolysis gives dextrose and a yellow substance insoluble in water.

—W. G.

Ketones; Reduction of aromatic —. W. D. Cohen. Rec. Trav. Chim., 1920, [IV.], 1, 243—279.

WHEN benzophenone is reduced in an absolutely neutral medium, e.g., absolute alcohol, by means of sunlight, benzopinacolone is the only product formed. The velocity of the reduction is affected by several factors such as the nature and concentration of the alcohol, and the amount of active light. It varies considerably with different aromatic ketones. (See further J. Chem. Soc., Apr., 1920.)—W. G.

Chloroform; Testing of —. Utz. Pharm. Zentr., 1917, 58, 1—5.

FOR the detection of decomposition products in chloroform, particularly those due to the action of sunlight, the benzidine test described originally by Budde (Geb. Militärsanitätswesen, No. 55, 120) is useful. A small quantity of benzidine is dissolved in 10 c.c. of the sample. With pure chloroform the solution does not exhibit any change when kept in the dark for 24 hours; if chloral is present, a faint pink coloration is obtained, and this shows a bluish tint after some time. Chloroform containing phosgene, hydrochloric acid, or chlorine at once yields a turbid solution, and a precipitate may form if the amount of these impurities is large—W. P. S.

Acids; Preparation of aliphatic — by catalytic oxidation of primary alcohols. A. Mailhe and F. de Godon. Comptes rend., 1920, 170, 517—519.

THE vapours of primary aliphatic alcohols readily undergo oxidation when passed over finely-divided copper at 260°—270° C. From 100 c.c. of ethyl alcohol the highest yield of acetic acid was 18.18 grms., together with 12 c.c. of acetaldehyde.—W. G.

Methyl chloride and bromide; Preparation of — from dimethyl sulphate. C. Boulin and L. J. Simon. Comptes rend., 1920, 170, 595—597.

METHYL chloride may readily be prepared by allow-

ing dimethyl sulphate to drop into hydrochloric acid (16° B., sp. gr. 1.125) at about 50° C., or into a concentrated solution of sodium chloride at 60°—65° C. Similarly methyl bromide may be prepared by using hydrobromic acid at 45°—50° C., or, preferably, a concentrated solution of an alkali bromide, slightly acidified with sulphuric acid, at 30°—35° C. In all these cases the yield is about 90% of theory.—W. G.

Ethylene; Chlorination of — in the presence of calcium chloride. J. A. Smythe. Gas. J., 1920, 149, 691—692.

ETHYLENE and chlorine react very readily in the presence of calcium chloride. A mixed product, containing 50—60% of ethylene dichloride is obtained. Much heat is disengaged, and the apparatus should be cooled during the operation. The products are purified by fractionation. The chlorinated product contains, on the average, 50% of dichloroethane, 25% of trichloroethane, and 25% of higher-boiling products. The calcium chloride apparently acts as a catalyst, but its activity may be due to the presence of a small amount of iron (1 in 50,000 estimated colorimetrically).—A. G.

Chromates; Photo-oxidation of organic compounds by —. J. Plotnikow. Z. wiss. Phot., 1919, 19, 40—56.

ETHYL alcohol is oxidised by ammonium chromate and bichromate in the presence of light of wave length $\lambda = 436\mu$ according to a linear equation. The velocity constant is proportional to the alcohol concentration, and approaches a maximum with increasing salt concentration. The temperature coefficient of the reaction is 1.02. (See also J. Chem. Soc., Apr., 1920.)—J. F. S.

Catechol. Elsner. See III.

Titration of mixed acids. Kolthoff. See XXIII.

PATENTS.

Acetone; Process of manufacturing —. H. W. Matheson, Shawinigan Falls, Canada. Eng. Pat. 138,679, 23.1.19. (Appl. 1729/19.)

ACETIC acid vapour is passed through a metal tube heated to 375°—525° C., and filled with metal balls coated with a catalyst, e.g., a mixture of 75 to 95% of lime and 25 to 5% of magnesia, or the oxide, hydroxide, carbonate, or acetate of any metals the acetates of which are converted to acetone on heating. The greater part of the acetone produced is condensed by passing the escaping gases through a water-cooled condenser, and the last traces are recovered by scrubbing the residual gases with water.—L. A. C.

Ether; Process for purifying —. C. Claessen, Berlin. Ger. Pat. 298,822, 28.11.15.

ETHER of sufficient purity for use in the gelatinisation of nitrocellulose, even if it has been prepared from denatured alcohol, is obtained by treating the crude product containing aldehydes with solid alkali hydroxides, with subsequent separation of the product from the hydroxides and aldehyde-resin.—L. A. C.

Sterile virus for medicinal use; Production of —. Quarzlampen Ges.m.b.H., Hanau. Ger. Pat. 314,859, 24.2.14.

RADIATIONS from chemically active sources, e.g., ultra-violet rays, are allowed to fall upon vaccine suspensions long enough to destroy harmful bacteria. The virus has a greater resistance to the bactericidal action of the rays, and its activity is reduced to a negligible extent only.—H. J. H.

Lecithin; Process for purifying —. C. F. Hildebrandt, Hamburg. Ger. Pat. 315,941, 31.12.15.

CRUDE lecithin is dissolved in water or other solvent, and sufficient dilute mineral or organic acid is added to precipitate the lecithin without saponification of the same, i.e., the acid concentration must be less than 1%. Impurities and adulterants remain in solution, and the product may be further purified by repeating the process.—L. A. C.

Formaldehyde, methyl alcohol, methyl formate, and acetone; Production of — by dry distillation of formates. K. Hofmann, Charlottenburg. Ger. Pats. (A) 316,216, 24.1.17, and (n) 316,217, 12.2.18.

(A) BASIC compounds formed during the low temperature dry distillation of formates, e.g., zinc formate, which hinder the production of formaldehyde, methyl alcohol, methyl formate, and acetone, and promote the formation of undesired compounds, are neutralised by the continuous or intermittent addition of formic acid during the distillation. (a) The production of formaldehyde etc. by the dry distillation of formates is increased by the presence of feebly acid compounds such as zinc or iron sulphate, precipitated silica, and zinc, iron, or stannic phosphate, and the decomposition takes place at a lower temperature. Whereas calcium and zinc formate yield respectively 17% and 30%, a mixture of 2.5 parts of zinc sulphate and calcium formate yields 50% of a mixture of formaldehyde and methyl alcohol in accordance with the equations: $-2\text{CH}_3\text{O}_2 = \text{CH}_3\text{O} + \text{CO}_2 + \text{H}_2\text{O}$ and $3\text{CH}_3\text{O}_2 = \text{CH}_3\text{OH} + 2\text{CO}_2 + \text{H}_2\text{O}$, and the decomposition is effected at $250^\circ\text{--}280^\circ\text{C}$. instead of about 100°C . higher. Excess of zinc sulphate, iron or acid stannic phosphate increases the yield of formaldehyde; precipitated silica promotes the production of methyl alcohol at the expense of formaldehyde.—L. A. C.

Arsenical compounds; Aromatic —. Rockefeller Institute for Medical Research, Assignees of W. A. Jacobs, W. H. Brown, M. Heidelberger, and L. Pearce, New York. Eng. Pat. 122,819, 21.10.18. (Appl. 17,172/18.) Int. Conv., 28.1.18. Addition to 120,385 (U.S. Pat. 1,280,123; this J., 1919, 268 A).

SEE U.S. Pat. 1,280,127 of 1918; this J., 1919, 268 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[Photographic] sensitometer; New non-intermittent —. L. A. Jones. Phot. J., 1920, 60, 80—98.

Two instruments of the continuous exposure, variable time type are described. In the second

instrument, which is better adapted for routine work, a shutter, actuated by a solenoid and ratchet, moves quickly but discontinuously across the sensitive surface at definite time intervals. In the timing mechanism, which controls the solenoid, a cinema film, moved at a uniform speed by a governed electric motor, is provided with a series of collinear apertures spaced from one another at distances corresponding with the exposure ratios required; the distances are measured in terms of the edge perforations to allow for normal variations in the length of the cinema film. One arm of a lever rests on the film in line with the operating apertures, into which successively it drops as the film moves; the lever carries an electric contact point so that the current operating the solenoid is completed when the lever drops. Other perforations etc. are arranged so that the depression of a contact switch starts the whole apparatus, which continues in operation until the exposure is finished and is then automatically cut off. A number of exposure machines may be connected at a central station with corresponding timing mechanisms operated by the same motor. Tables are given showing the timing mechanism to be satisfactory when tested against a chronograph and showing the speed and gamma obtained for a photographic plate to be independent of the absolute exposure, not variable with it as is the case with intermittent exposure machines.—B. V. S.

[Light] filters; Ultra-violet transparent —. A. Miethe and E. Stenger. Z. wiss. Phot., 1919, 19, 57—68.

TARTRAZINE in solutions 1:1000—1:120,000 shows a maximum transparency from $300\text{--}308\mu$ in the most concentrated solution to $280\text{--}391\mu$ in the most dilute. Filter Yellow in the same concentrations has a maximum transparency $296\text{--}308\mu$ with the most concentrated solutions, which increases to $270\text{--}500\mu$ with the most dilute. Martius' Yellow in 1:1000 solution is transparent for wave lengths $321\text{--}330\mu$ and in 1:20000 solution for $296\text{--}374\mu$. Nitrosodimethylaniline is transparent in 1:90000 solution over the range $299\text{--}365\mu$. Fluorescein increases in transparency down to 260μ with increasing dilution. Eosin in 1:1000 is transparent, $368\text{--}390\mu$, and in 1:10000, $271\text{--}470\mu$. The quartz silver mirror is transparent over the range $308\text{--}330\mu$ with a 2 seconds exposure of an iron-carbon arc, whilst with 640 seconds exposure the transparency is over the range $302\text{--}388\mu$.—J. F. S.

[Photographic] development under tropical conditions. A. J. Agnew. Phot. J., 1920, 60, 120—122.

THE sensitive film, before development, is treated in a hardening solution containing formalin and a suitable salt (Eng. Pat. 128,377; this J., 1919, 602 A). The most useful salts are sodium acetate, borate, bicarbonate, chromate, citrate, oxalate, phosphate, sulphate, and tartrate; potassium and magnesium salts are not quite so effective, and ammonium salts are not generally suitable because of the possibility of the liberation of ammonia in development. The hardening process also reduces the rate of development and the tendency to fog, so that development is easier of control than is otherwise the case at high temperatures. Subsequent intensification and reduction processes are not interfered with. There has not been noticed any tendency to separation of the film from the glass after drying. No reticulation is produced, after the hardening process, by considerable variation in the temperatures of developer, fixing bath, and washing waters.—B. V. S.

Dye impression [photographic] printing process. F. W. Donisthorpe. Phot. J., 1920, 60, 119.

A NEGATIVE, on paper, glass, or other suitable support, is treated in a special preparing bath for

about 10 min., rinsed, and then treated with a dye solution for 3–10 min., according to the exposure and development of the negative, a longer immersion being required for over-development or over-exposure. After rinsing the dyed negative it is ready for the production of positives, in the colour of the dye used, by pressing on to it damp gelatin-coated or baryta-coated paper, contact for about 1 min. being requisite. After taking off, the print merely requires quick drying.—B. V. S.

PATENT.

Coloured photographic images and method of producing the same. J. M. Blaney, Verona, N.J., Assignor to Prizma, Inc. U.S. Pat. 1,331,092, 17.2.20. Appl., 22.5.18.

By treatment of a silver image with a solution of a suitable tin salt an insoluble tin compound is deposited on the image and this is then coloured by treatment with a dye solution.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Drying explosives in a tunnel dryer, and recovery of the solvents. G. Weissenberger. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 33–36.

The apparatus described consists of a tunnel having a separate compartment at each end with inner and outer doors, and serving as intermediate chambers for admitting or discharging bogeys containing the explosive without loss of vapour or heat from the main tunnel. By means of a fan, air is circulated through the tunnel in an opposite direction to the passage of the explosive, the air being heated before entering the tunnel, and after leaving the tunnel passing successively through a pre-cooler and two final coolers; the cooled air from the latter is utilised as a cooling agent for the pre-cooler and, at the same time, undergoes a preliminary heating before returning to the heater and tunnel. In the final coolers, the temperature is lowered to $-50^{\circ}\text{C}.$, and by this means the air is completely freed from moisture and volatile solvent and acquires a high drying capacity. To condense the volatile solvents from the mist in the coolers, the air should be passed through a centrifuge. Risk of fire from static charges of electricity may be prevented by earthing the machine. Means are provided for drawing samples and controlling the temperature, and the rate of passage of the explosive through the dryer may also be regulated. In comparison with ordinary air or vacuum dryers, the apparatus requires only half the fuel consumption, provides continuous and more complete drying and recovery of solvents, and demands little supervision.—W. J. W.

Nitrocellulose; Examination of —. A. Schrimpf. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 17–20, 38–41, 53–56.

For the estimation of ash, 5 grms. is saturated with 25 c.c. of pure nitric acid (sp. gr. 1.4) in a platinum dish and evaporated to dryness on a water-bath. The residue is heated on an asbestos plate and finally over the naked flame. After cooling it is treated with a little water, again evaporated, and ignited. Foreign matter and unnitrated cellulose are determined by treating 5 grms. with 125 c.c. of a clear, aqueous solution of sodium sulphide (200 grms. in 800 c.c.) in a porcelain dish and gently boiling for 10 min. The residue is washed with water on a dry tared linen filter, previously treated with sodium sulphide, hydrochloric acid,

and water, and dried. The weight of the residue gives the foreign matter from which the unnitrated cellulose is calculated by deducting the ash. Solubility in ether-alcohol is influenced by factors such as the strength of the alcohol and the manner in which the solvents are added. 2 grms. of nitrocellulose after drying over sulphuric acid in a vacuum desiccator is transferred to a cylinder containing about 100 c.c. of ether-alcohol (ether, sp. gr. 0.72, 2 parts; alcohol, 95–96%, 1 part), and rinsed in with a further 100 c.c. After periodical shaking for 6 hours, the nitrocellulose is allowed to settle, and 100 c.c. of the clear liquid is drawn off into a glass dish and evaporated on a water-bath, till the residue assumes a horny appearance, at which stage the drying is completed in a steam-oven. For nitrogen estimations the Schultze-Tiemann method is more accurate than the Lunge method. Owing to shortage of rubber, a modified apparatus has been devised, in which the connections are dispensed with. For determination of sulphuric esters Piest's method is employed (this J., 1913, 1087). In the case of nitrocellulose derived from wood cellulose which contains a considerable amount of calcium sulphate and calcium carbonate, it is necessary to estimate these in order to allocate the correct amount of sulphuric acid to the esters. *Stability tests.* An outline and discussion of various methods are given, but Bergmann and Junk's (this J., 1904, 953), which is the official test, is employed by the author.—W. J. W.

Explosives; Sensitiveness of — to frictional impact [and new pendulum device for measuring same]. S. P. Howell. U.S. Bureau of Mines, Tech. Paper 234, Sept., 1919. 17 pages.

For determining the sensitiveness of explosives more uniformly than is possible by the broomstick and raw hide mallet tests the Bureau of Mines have adopted a pendulum friction device. This comprises a smooth-faced steel anvil, 8.3 cm. \times 30.5 cm., with three grooves for holding the explosive, and a steel shoe faced with hardwood fibre, 8.3 cm. wide, the face having a radius of curvature of 26.7 cm. This shoe swings in a radius of 2 m. from a height of 1.5 m. and is weighted with an additional 20 kilos. For more severe tests a steel shoe without wood fibre is used. 7 grms. of explosive is taken for test, and ten trials are made, the anvil and shoe being thoroughly cleaned after each trial. Tests are carried out at 14° – $30^{\circ}\text{C}.$ Observations are made as to complete or partial explosion, burning, and cracking. An explosive is considered safe if it fails to give more than an almost indistinguishable local cracking. Increase of temperature failed to give discrimination between various explosives. With the steel shoe it was found that nitroglycerin-dynamites and gelatin-dynamites are more sensitive than black blasting powders, blasting gelatin, ammonia dynamites, and explosives containing organic nitrates other than nitroglycerin. Trinitraniline, tetryl, 50/50 amatol, and 60/40 sodatol have a higher sensitiveness than trinitrotoluene, picric acid, ammonium picrate, 85/15 and 80/20 amatol, and 80/20 sodatol. Potassium chlorate explosives are extremely sensitive but can be made sufficiently insensitive by addition of mineral or vegetable oils, or aromatic nitro-compounds. The presence of pyrites-bearing coal greatly increases the sensitiveness of chlorate explosives; even the friction of a copper needle caused ignition in some cases.—W. J. W.

Trimethyleneglycol; Determination of — in distilled (dynamite) glycerin and first runnings. C. A. Rojahn. Z. anal. Chem., 1919, 58, 433–442. The sp. gr. of glycerin (1.2653 at $15^{\circ}/15^{\circ}\text{C}.$) is lowered by the presence of trimethyleneglycol (sp.

gr. 1.0573) or water, or both. If the water content is known the amount of the glycol present may be calculated from the sp. gr. The water is determined by drying 2 grms. of the sample on asbestos under reduced pressure over phosphorus pentoxide; the drying should not be prolonged for more than 48 hours, as the glycol is slightly volatile. Graphs and tables are given showing the percentages of the glycol present in glycerin samples of varying sp. gr. and water content.—W. P. S.

Liquid air; Production and use of — for blasting. H. Diederichs. Stahl u. Eisen, 1920, 40, 52—56.

Liquid air containing about 85% of oxygen is now used to a considerable extent for blasting purposes in non-flery mines. With the use of suitable fillers capable of absorbing $3\frac{1}{2}$ to 4 times their weight of liquid air, it is possible to fire simultaneously 10 to 12 35-mm. cartridges and a still greater number of cartridges of larger diameter. The cartridges in their simplest form consist of paper or fabric containers filled with cork-carbon, cork-powder, soot, etc. They are immersed in the liquid air shortly before use and become saturated in 5 to 10 mins. They have a useful "life" after removal from the bath of 8 to 12 mins. Firing is effected by fuse, direct or in conjunction with a detonator cap, and also electrically. The liquid air is transported in 10-litre containers, made of special glass or porcelain, packed in outer wood or iron vessels.—T. St.

Coal mines; An analytical method for detecting blown-out shots in —. G. F. Hutchison and J. Barab. U.S. Bureau of Mines. Tech. Paper, 210, Oct., 1919. 18 pages.

CHEMICAL tests made on scrapings from a shot-hole in a coal mine, after a blown-out shot, in comparison with tests made on a normal sample of the same coal, enable conclusions to be drawn regarding the nature of the explosive fired and whether the explosive detonated completely or not. Results are given of the products formed under known conditions and examples of deductions drawn from results in unknown cases.—T. St.

Mercury fulminate; Theories regarding the grey and white varieties of —. A. Langhans. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 7—9, 23—24.

PATENTS.

Octonitroethylenediphenyldiamine; Preparation of —. Farb. vorm. Meister Lucius, und Brüning, Höchst. Ger. Pat. 300,082, 2.6.15.

OCTONITROETHYLENEDIPHENYLDIAMINE, a highly-sensitive explosive having the constitution $C_{12}H_2(NO_2)_8$, $N(NO_2)(CH_2)_2N(NO_2)C_6H_4(NO_2)_3$, is prepared by the action of strong nitric acid on 2.4.2'.4'-tetranitroethylenediphenyldiamine or on 2.4.6.2'.4'.6'-hexanitroethylenediphenyldiamine. The product is practically insoluble in organic solvents, but crystallises from concentrated nitric acid in colourless rhombic prisms of m. pt. 213° C. (decomp.).

—L. A. C.

Wood cellulose and cotton; Production of material for nitration from —. C. Claessen, Berlin. Ger. Pat. 300,844, 18.7.15.

Wood cellulose and cotton are mixed together with water to a thick pulp, dried, and further mixed. The bleaching may precede or follow the wet mixing. In this way equal parts of the materials can be mixed and nitrated together so as to yield a collodion dissolving to a clear liquid and equal in stability to that obtained from nitro-cotton.—H. J. H.

XXIII.—ANALYSIS.

Liquids; Apparatus for the extraction of —. K. Brauer and E. W. Ebert. Chem.-Zeit., 1920, 44, 214.

THE apparatus is similar in shape to a Soxhlet extractor, and is intended for the extraction of a liquid with a solvent of higher sp. gr.; in place of the usual siphon is a narrow tube extending upwards from the bottom of the cylinder and entering the side tube, up which the vapour of the solvent passes. When the solvent has collected under the liquid to a height level with the point at which the narrow tube enters the side tube, it (the solvent) flows back gradually into the extraction flask. A tap is provided between the cylinder and stem of the apparatus for the purpose of drawing off the portion of the solvent which remains in the apparatus when the extraction is completed.—W. P. S.

Filtration through filter-paper; Accelerated —. G. Bruhns. Chem.-Zeit., 1920, 44, 207.

THE rate of flow through a simple folded filter-paper may be increased by turning back the loose end of the three-fold layer so that it projects into the funnel like a tongue.—W. P. S.

Precipitates; Machine for washing —. E. Sinkinson. Analyst, 1920, 45, 94—97.

A JUNG at one end of a counterpoised rocking arm supports the funnel containing the precipitate to be washed; the wash water is admitted to the funnel through a rotating jet, and when a predetermined weight of water has collected in the funnel the rocking arm falls. This movement operates a commutator connected with a motor which controls a valve on the water supply and the latter is cut off; when the water has flowed from the funnel the rocking arm rises, the motor is reversed and the valve opened so that water is again admitted to the funnel. These operations proceed automatically as long as current is supplied to the motor.—W. P. S.

Platinum wire; Cheap substitute for — for flame tests. A. Ehringhaus. Centr. Min., 1919, 192.

THE platinum wire used for carrying out flame tests can simply and cheaply be replaced by a strip of filter paper. To test a solution, a strip of pure filter paper is folded several times and one end dipped in the solution. This end is then held in the outer flame of a Bunsen burner. If an insoluble salt is to be tested the strip is first dipped in dilute hydrochloric acid and a little of the salt is then sprinkled on the damp end. In either case a good, pure flame coloration is obtained, which lasts as long as the paper is prevented from burning by the moisture or the salt. A lasting, monochromatic flame can be obtained by dipping one end of a strip of paper in a vessel containing the dissolved salt, the other end being held in the Bunsen flame. The paper is prevented from burning by a crust of salt which soon forms.—E. H. R.

Halogens; Copper flame test for — in air. A. B. Lamb, P. W. Carleton, W. S. Hughes, and L. W. Nichols. J. Amer. Chem. Soc., 1920, 42, 78—84.

ONE part of halogen (free or combined) in 100 million parts of air may be detected and approximately estimated by allowing the air to pass over a roll of fine copper gauze heated to incipient redness, and afterwards sharply heating the coil in a hot colourless flame and observing the green flame produced. The quantitative determination is made by measuring the quantity of air which must pass over the coil in order that a green flame may be produced when the coil is subsequently sharply heated.

—J. F. S.

Methyl orange; Effect of a change in temperature on the colour changes of — and on the accuracy of titrations. H. T. Tizard and J. R. H. Whiston. Chem. Soc. Trans., 1920, 117, 150—156.

The depth of colour of methyl orange in solutions of varying acidity within the limits of sensitiveness (hydron concentration 10^{-1} – 10^{-6}) was determined at three different temperatures by means of a modified Donnan colorimeter, and from the results the following values for the dissociation constant of the indicator were obtained: 10°C. , $K=2.1 \times 10^{-4}$; 25°C. , $K=3.8 \times 10^{-4}$; 40°C. , $K=5.5 \times 10^{-4}$. It is shown from these results that the concentration of hydron necessary to produce any definite depth of colour is doubled by raising the temperature from 15° to 40°C. , and consequently for the quantitative determination of hydriens in a solution by the methyl orange method it is essential to maintain a constant temperature. The effect of a change in temperature on the accuracy of an ordinary titration is, however, very slight, since, for example, the increase in concentration of hydrogen ions with increased temperature in a solution of a salt of a weak base and a strong acid tends to cancel the effect of the increased dissociation of the methyl orange.—G. F. M.

Indicators; Sodium alizarinsulphonate and other —. Mestrezat. J. Pharm. Chim., 1920, 21, 185—192.

As compared with certain other indicators (phenolphthalein, methyl orange, litmus, laemoid, Porrier's Blue, etc.) sodium alizarinsulphonate has the advantage that it may be used for the titration of ammonia and phosphoric acid in addition to being a sensitive indicator for strong acids and alkali hydroxides. It cannot, however, be used for the titration of carbonates. Commercial sodium alizarinsulphonate is always alkaline in reaction and needs to be neutralised with sulphuric acid before use as an indicator.—W. P. S.

Acids; Titration of mixed — by conductivity methods. I. M. Keltchoff. Rec. Trav. Chim., 1920 [IV.] 1, 280—302.

The author's results confirm the work of Meerburg (this J., 1919, 880 A). It is not possible to estimate lactic acid in gastric juice by the conductivity titration method, but the method is applicable to the estimation of the total acidity of the juice. It is possible by this method to estimate, with a very fair degree of accuracy either small amounts of weak acids, such as acetic acid, mixed with larger amounts of strong acids, such as hydrochloric acid, or *vice versa*. The method is thus applicable to the estimation of mineral acids in vinegar, particularly when the amount present exceeds 1% calculated as hydrochloric acid. Weak bases may similarly be estimated in the presence of strong bases by the conductivity titration method.—W. G.

Ammonia; Distillation of —. B. S. Davisson. J. Ind. Eng. Chem., 1920, 12, 176—177.

THE use of the scrubbing device of block tin with tin condenser (this J., 1919, 443 A) is recommended for the distillation of ammonia in the determination of nitric nitrogen by the method previously described (this J., 1919, 332 A). For the distillation of ammonia in Kjeldahl's method the solution is slowly distilled in this apparatus for 20 mins., about 80 c.c. of distillate being collected. The condenser is then drained, the distillation continued more rapidly for 15 mins., the receiver then removed, covered to prevent absorption of carbon dioxide, and the liquid cooled and titrated. Under these conditions the last traces of ammonia are removed from the condenser, whilst the volume of solution in the receiving flask is kept small (to prevent hydrolysis of

the indicator salt), and that of the solution in the distilling flask is not reduced.—C. A. M.

Mercury; Determination of — by Glückmann's method. A. Abelmann. Z. anal. Chem., 1919, 58, 443—445.

GLÜCKMANN'S method (see Peters, this J., 1900, 931) yields unreliable results owing to the solubility of mercury oxalate and the tendency to the formation of basic salts. This may be prevented by acidifying the mercury solution with 2–3 c.c. of 5N nitric acid, using a large excess of oxalic acid for the precipitation, and adding 50 c.c. of saturated potassium nitrate solution before the excess of oxalic acid is titrated with permanganate solution. The potassium nitrate solution should be tested previously with permanganate to ensure the absence of reducing substances.—W. P. S.

Zirconium and titanium; Separation of — as phosphates. J. Brown and H. T. Madden. J. Amer. Chem. Soc., 1920, 42, 36—39.

A SOLUTION of zirconium and titanium sulphates containing 1–2% by vol. of sulphuric acid is treated with an excess of hydrogen peroxide and then with an excess of di-sodium or di-ammonium phosphate and the mixture allowed to stand overnight. The zirconium phosphate is filtered off and washed with water containing a few drops of sulphuric acid and a little hydrogen peroxide. If the precipitate is coloured yellow by titanium it is fused with sodium carbonate, extracted with water, and re-dissolved by fusing with potassium bisulphate and then treating with dilute sulphuric acid. The zirconium is then re-precipitated as above. The phosphate is converted into oxide by fusing with sodium carbonate, extracting with water, dissolving the residue in hydrochloric acid, and precipitating with ammonia. The precipitate is washed, dried, ignited, and weighed as the dioxide. The combined filtrates from the zirconium precipitation are boiled to decompose hydrogen peroxide and the acidity adjusted so that the sulphuric acid amounts to 2% by vol. An excess of di-sodium or di-ammonium phosphate is added, the mixture allowed to stand for an hour and filtered. The titanium phosphate is washed, converted into dioxide, as in the case of zirconium, and weighed.—J. F. S.

Cuprous chloride; Preparation of a hydrochloric acid solution of — for use in gas analysis. F. C. Krauskopf and L. H. Purdy. J. Ind. Eng. Chem., 1920, 12, 158—161.

COMPARATIVE tests showed that the efficiency of cuprous chloride solution for the absorption of carbon monoxide is not deleteriously affected by the presence of relatively large amounts of stannous and stannic chlorides. A satisfactory reagent is obtained by reducing cupric chloride in acid solution by means of stannous chloride, and if a small excess of stannous chloride is used the solution may be exposed to air during transference from one vessel to another without the cuprous chloride becoming oxidised. Further, the solution may be renewed, after saturation with carbon monoxide, by heating to 60° – 70°C. to drive off the gas, a few drops of concentrated stannous chloride solution being added to correct any oxidation which might occur.—S. S. A.

Carbon dioxide, oxygen and combustible gases; Estimation of — by Krogh's method of micro-analysis. H. O. Schmit-Jensen. Biochem. J., 1920, 14, 4—24.

KROGH'S method of gas analysis may be used to estimate hydrogen and carbon monoxide in very small gas samples. Hydrogen is absorbed by a solution of 0.66 gm. of colloidal palladium and 0.42

grm. of sodium picrate in 20 grms. of water, and carbon monoxide by an acid solution of cuprous chloride. By a modification of Krogh's apparatus carbon dioxide and oxygen may be estimated by absorption, hydrogen and methane by combustion, carbon monoxide either by absorption or combustion, and nitrogen by difference. The fractional combustion of hydrogen and methane is also possible if the bubble of gas has a volume of at least 80 cub. mm. The error in the readings is about 0.1 cub. mm. (See also J. Chem. Soc., April, 1920).—J. P. S.

Oxygen; Determination of — by the copper-ammonia-ammonium chloride reagent. W. L. Badger. J. Ind. Chem., 1920, 12, 161—161.

HEMPEL's method for the absorption of oxygen by means of metallic copper spirals covered with a solution containing equal parts of saturated ammonium carbonate solution and ammonia of sp. gr. 0.93, was the basis for a series of experiments in which varying strengths of ammonia and ammonium salts other than the carbonate were used. The best results were obtained with a mixture of one part of concentrated ammonia (sp. gr. 0.9) and one of water saturated with ammonium chloride, the specific absorption (this J., 1915, 853) of this mixture being 55—60 vols. This reagent is cleaner and has a longer life than pyrogallate; unlike phosphorus, it is unaffected by catalysts, and it is readily prepared and is active at almost any temperature. On the other hand, it cannot be used for mixtures containing carbon monoxide or acetylene, and when fresh it is liable to leave measurable amounts of ammonia in the gas.—S. S. A.

Zinc; Determination of — in organic materials (urine, faeces, foods, etc.) and remarks on the zinc content of reagents and apparatus. A. Weitzel. Arb. & Reichs-Gesundh.-Amt, 1919, 54, 476—493. Chem. Zentr., 1920, 91, II., 5—6.

Two methods of determining zinc in organic materials are described. In the first the material is incinerated, the residue dissolved in acid, the solution treated with hydrogen sulphide, and the filtrate precipitated with potassium ferrocyanide. The precipitate is filtered off, washed, dissolved in concentrated sulphuric acid, and the filtrate treated in the usual way with ammonium sulphide to precipitate zinc sulphide. The latter is dissolved in hydrochloric acid and again precipitated as sulphide from an acetic acid solution. After solution of the precipitate in hydrochloric acid the liquid is treated with caustic soda and the precipitate ignited and weighed as zinc oxide. In the second method the acid filtrate from the first hydrogen sulphide treatment is oxidised with nitric acid, and the iron precipitated as basic acetate, together with any phosphate present. The precipitate is redissolved and re-precipitated two or more times until no further zinc can be detected in the filtrate. From the combined filtrates the zinc is precipitated with hydrogen sulphide, and the zinc sulphide is converted into, and weighed as, oxide, as in the first method. While both methods give equally accurate results, the second is preferable, as it uses smaller quantities of reagents and may be carried out in a shorter time. The author lays stress on the danger of contamination with zinc from the use of Jena glassware in the analysis.—A. R. P.

Ammonium molybdate; Recovery of — from phosphoric acid determinations. H. Neubauer and E. Wolferts. Z. anal. Chem., 1919, 58, 445—448.

The mixed filtrates, precipitates, etc., are neutralised partially with ammonia, the molybdic acid is precipitated at 80° C. with sodium phosphate, and the yellow precipitate is collected, washed, and dried. Four kilos. of the dry yellow powder is dis-

solved in 6 litres of water and 4 litres of ammonia (sp. gr. 0.91), and a solution of 500 grms. of crystallised magnesium nitrate is added; the total volume should be not less than 11 litres. The ammonium magnesium phosphate is removed by filtration and the filtrate is concentrated, ammonia being added from time to time to prevent dissociation and separation of molybdic acid. Crystals of ammonium molybdate are removed occasionally until the solution has a volume of about 750 c.c. On cooling, magnesium nitrate separates with the ammonium molybdate, but may be removed by washing the crystals of the latter with a small quantity of water. The ammonium molybdate thus obtained is recrystallised, first from very dilute ammonia solution and then from water.—W. P. S.

Densities; Relations between relative —, absolute density, and apparent weight of solutions. O. Chéneau. Bull. Assoc. Chim. Suér., 1919, 37, 175—181.

A TABLE is given to facilitate the conversion of specific gravities, determined at 15° C., from one basis of reference to another. One column shows absolute densities (15° C. in *vacuo*/4° C. in *vacuo*) ranging from 0.7 to 1.8, to five places of decimals, and four parallel columns show the corrections to be added or subtracted to obtain corresponding values referred to any of the following bases: 15° C. in air/15° C. in air, 15° C. in *vacuo*/15° C. in *vacuo*, 15° C. in *vacuo*/15.5° C. in *vacuo*, and 15° C. in air/4° C. in *vacuo*.—J. H. L.

Spectrophotometry; Photo-electric — by the null method. K. S. Gibson. U.S. Bureau of Standards, Scient. Paper 349, Oct. 11, 1919. 28 pages.

PATENTS.

Water vapour; Method of and apparatus for detecting — or either of the gaseous components thereof. H. E. F. Goold-Adams and W. R. Bousfield, London, and G. W. Todd, Newcastle-on-Tyne. Eng. Pat. 137,547, 28.9.17. (Appl. 14,030/17.)

THE gases suspected of containing water vapour, or either oxygen or hydrogen (which must first be converted into water by passing over a suitable catalyst) are passed over a salt such as an alkali chloride or nitrate, which is arranged to form part of an electric circuit. If the partial pressure of the water vapour exceeds the critical hydration pressure of the particular salt selected, the salt takes up water and allows a current to pass in the circuit, whereby a suitable indication may be given by means of a galvanometer or an electric bell operated by a relay. The salt is conveniently placed between a pair of wire gauze electrodes through which the gases are passed. The device is particularly applicable in cases where it is necessary to guard against an explosive mixture of oxygen and hydrogen in gaseous reactions, such as in the synthetic production of ammonia, in which cases a continuous sampling of the mixed gases is secured by means of a by-pass, and a salt is selected, of which the hydration pressure is approximately equal to the partial pressure of the aqueous vapour corresponding to the percentage of oxygen against which a warning is required.—G. F. M.

Base-metal alloys containing chromium and nickel for thermocouples. W. C. Heraeus, G.m.b.H., Hanau. Ger. Pat. 306,359, 17.6.17. Addition to 302,452 (this J., 1920, 86A).

By the addition of varying proportions of cobalt to nickel-chromium alloys thermocouples possessing linear, convex, or concave, thermo-electric power curves can be constructed. By using alloys containing cobalt a couple can be produced having a thermo-electric power more nearly corresponding to that of the platinum-platinum-rhodium couple between 500° C. and 1300° C. than is the case in the absence of cobalt.—J. S. G. T.

[*Electric*] *resistance thermometer.* W. C. Heraeus, G.m.b.H., Hanau. Ger. Pat. 316,416, 1.4.1919.

THE resistance element is composed of boron. This possesses a temperature coefficient some 10 to 20 times greater than most metals customarily employed. Apparatus used therewith can therefore be of smaller sensitivity and consequently cheaper.

—J. S. G. T.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Adams. Conversion of liquids, fluids, and oils. 9484. Apr. 1. (U.S., 11.4.19.)

Barrett Co. Controlling temperature reactions. 9505. Apr. 1. (U.S., 11.6.19.)

Caspari. Filtering-media and diaphragms resistant to halogens and corrosive fluids. 10,093. Apr. 10.

Drees and Frischer. Causing gases and liquids to react with one another. 9989. Apr. 9. (Ger., 20.10.17.)

Fuller Engineering Co. Pulverized fuel furnaces. 9123. Mar. 29. (U.S., 1.7.19.)

Henshaw, Whittell, and Holmes and Co. Apparatus for bringing liquids and gases into intimate contact. 9432. Apr. 1.

Lamhot. Rocking-furnaces. 9297. Mar. 31. (Fr., 3.4.19.)

Lamhot. Oil-fired furnaces. 9298. Mar. 31. (Fr., 3.4.19.)

Lamhot. Rotary hearths for furnaces. 9299. Mar. 31. (Fr., 3.4.19.)

Lewcock and Siderfin. Catalytic processes and contact reactions. 9957. Apr. 9.

Littleton. 9525. See XVIII.

Metcalfe. Tunnel kilns or furnaces. 9797. Apr. 7.

Motala Verkstads Nya Aktiebolag. Furnaces for pulverulent fuel. 9147. Mar. 29.

Schmiedel. Device for bringing gases or vapours and liquids into intimate contact. 9385. Mar. 31. (Ger., 11.8.19.)

Schuler. Grinding and abrading medium for tube mills. 9285. Mar. 31.

Schuler. Centrifugal separators. 9286. Mar. 31.

Selden, and Selden Co. Catalysis. 9766. Apr. 7.

Wade (Barrett Co.). Catalytic oxidation. 9504. Apr. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

21,470 (1918). Fenton and Vivian. Rotary kilns. (140,514.) Apr. 8.

3904 (1919). Sonsthagen. Means for feeding material through a rotating cylinder whilst subjected to roasting, mixing, etc. (140,880.) Apr. 14.

4276 (1919). Du Pont de Nemours and Co. Apparatus for use in recovering solvents. (123,752.) Apr. 8.

5605 (1919). Benjamin. Tunnel kilns. (140,578.) Apr. 8.

11,042 (1919). Fawcett, Preston, and Co., and Taylor. Tubular heating appliances of vacuum pans etc. (140,635.) Apr. 8.

16,383 (1919). Leinart. See XIX.

2581 (1920). Alexander (United Filters Corporation). Continuous vacuum filters. (141,001.) Apr. 14.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Adams. 9484. See I.

Anderson and Meikle. Apparatus for treating oil or tar. 9267. Mar. 31.

Beard. Quenching hot coke etc. 9314. Mar. 31.

De Laval Separator Co. Purifying lubricating-oil. 9676. Apr. 6. (U.S., 23.4.19.)

Jackson. Liquid fuel for internal combustion engines. 9818. Apr. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

55 (1919). Broadhead. Manufacture of gas or gases. (122,179.) Apr. 14.

17,805 (1919). Soc. de Fours à Coke et d'Enterprises Indus. Coke-ovens etc. (129,994.) Apr. 8.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

- Anderson and Meikle. 9267. *See* II.
 Atack and Clough. Manufacture of compounds of the anthraquinone series. 9305. Mar. 31.
 Barrett Co. Manufacture of tar. 9506. Apr. 1. (U.S., 7,2.20.)

COMPLETE SPECIFICATION ACCEPTED.

- 17,280 (1919). Silberrad. Manufacture of dinitrophenol. (140,955.) Apr. 14.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Glanzfaeden A.-G. Producing very fine artificial threads from cellulose solutions. 9100. Mar. 29. (Ger., 22,7.18.)
 Jackson (Griley-Unkle Engineering Co.). Tube-beaters for paper pulp. 9488. Apr. 1.
 Rintoul and others. 10,097 and 10,098. *See* XXII.
 Wade (Barrett Co.). Manufacture of fibrous material. 9503. Apr. 1.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Anderson and Meikle. 9268. *See* XX.
 Boocock, and Holmes and Co. Recovering ammonia from ammoniacal liquor. 9415. Apr. 1.
 Clayton. Apparatus for manufacture of oxygen compounds of sulphur. 10,004. Apr. 9.
 Klencko and Schmiedel. Production of sulphuric acid without chambers and towers. 9386. Mar. 31. (Ger., 8,8.19.)
 Mason. Method of making bisulphite of sodium etc. 9824. Apr. 8.
 Phillips. Manufacture of alkali silicates. 9994. Apr. 9.
 Wilderman. Processes and cells for electrolytic decomposition of alkaline salts. 9341. Mar. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

- 5979 (1918). Taliani. Catalytic oxidation of ammonia. (140,833.) Apr. 14.
 17,167 and 19,135 (1918). Calvert. Production of cyanogen compounds or cyanide. (140,484.) Apr. 8.
 19,585 (1918). Hood. Purification of sulphur. (140,844.) Apr. 14.
 19,940 (1918) and 13,816 (1919). Chrystal. Recovery of ammonia. (140,505.) Apr. 8.
 21,533 (1918). Soc. Indus. de Produits Chimiques. Converting alkali monochromates into bichromates. (122,172.) Apr. 8.
 14,958 (1919). Norsk Hydro-Elektrisk Kvaelfstoffaktieselskab. Sulphuric acid containing nitrogen oxides. (130,966.) Apr. 8.

VIII.—GLASS; CERAMICS.

APPLICATION.

- Assié. Manufacture of an abrasive and refractory material. 9685. Apr. 6. (Fr., 9,8.17.)

IX.—BUILDING MATERIALS.

APPLICATIONS.

- Phillips. Heat-insulating materials. 9995. Apr. 9.
 Simon. Process for decolorising veneers of exotic woods. 9256. Mar. 30. (Fr., 9,1.18.)
 Smitheman. Brick-making process. 9161. Mar. 30.

COMPLETE SPECIFICATION ACCEPTED.

- 3470 (1919). Hoare. Utilising slag as a building and other constructional material. (140,874.) Apr. 14.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Alexander (Metal and Thermit Corporation). Formation of tungsten alloys. 9633. Apr. 6.
 Amalgamated Zinc (de Bavay's), Ltd. Recovery of lead and silver from ores etc. 9149. Mar. 29. (Australia, 29,3.19.)
 Dean. 9483. *See* XI.
 Electrolytic Zinc Co. Electrolytic treatment of ores containing zinc etc. 9445. Apr. 1. (Australia, 4,4.19.)
 Lovelock, and Try and Son. Electrolytic deposition of iron, and treatment of the deposits. 9251. Mar. 30.
 Metropolitan-Vickers Electrical Co. Treating magnetisable material. 9651. Apr. 6. (U.S., 4,4.19.)
 Pearson and Saunders. Furnace for roasting and smelting ores. 10,041. Apr. 10.
 Syndicat Electro-Staal, and Vermaes. Manufacture of iron from iron ores. 9250. Mar. 30.
 Talbot. Metallurgical furnaces. 9455. Apr. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,997 (1918). Marsh. Treatment of metals or refractory materials, and electric furnaces therefor. (140,835.) Apr. 14.
 21,068—21,070 (1918). Soc. Anon. de Commentry Fourchambault et Decazeville. Alloys. (140,507—9.) Apr. 8.
 14,989 (1919). Tainton. Roasting ores or concentrates. (140,943.) Apr. 14.
 16,588 (1919). Sinclair. Metal-smelting furnaces. (140,948.) Apr. 14.
 23,747 (1919). Soc. des Alliages et Bronzes Forgeables. Tilting-crucible or melting-pot furnaces. (140,709.) Apr. 7.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Assié. Electric furnaces. 9686. Apr. 6. (Fr., 9,8.17.)
 Dean. Compound anode for electroplating. 9483. Apr. 1. (U.S., 12,12.17.)

I.—GENERAL; PLANT; MACHINERY.

Graphic mixture calculations. Wa. Ostwald. Chem.-Zeit., 1920, 44, 241—242.

WHEN it is required, from two or more materials containing two or more constituents in known proportions, to produce another mixture containing the same constituents in other proportions, the calculation can be greatly simplified by the use of the graphic method. In the simplest case, for example, where it is required from mixtures containing respectively 2.5% and 10% of a constituent *a* to prepare one containing 8.25% of *a*, a horizontal percentage scale is plotted and at its extremities are erected perpendiculars on which are set off the proportions of *a* present in the two original materials. The two points thus obtained are joined by a straight line. On this line a point is found, the perpendicular distance of which from the horizontal line corresponds to 8.25%, and from this point a perpendicular is dropped which divides the horizontal line in the ratio in which the two original materials must be taken to give the required mixture. The method can be applied to problems of considerable complexity, and gives an approximate result when no exact solution is possible. (See also Donnan; this J., 1916, 3.)

E. H. R.

Filter plates and frames; Classification of — and their general usage. D. R. Sperry. Chem. and Met. Eng., 1920, 22, 493—496.

PATENTS.

Conducting a liquid and gas soluble in said liquid through a closed cycle of thermal operations; Apparatus for —. C. H. Beadle, Southampton. Eng. Pat. 139,732, 24.9.19. (Appl. 23,491/19.)

AN apparatus is described for rendering heat energy available as mechanical energy or for purposes of refrigeration by means of the cycle of operations described in Eng. Pat. 20,267 of 1914. Gas is evolved from a liquid under pressure by means of heat transferred from liquid and gas at another part of the cycle, the evolved gas does mechanical work in an engine and the heat thus lost is regained from an external source, which may be waste or natural heat; the reheated gas is absorbed in the liquid, and the latter then passes to the generator where gas is evolved. A single vessel, preferably consisting of a number of vertical concentric tubes, is used for the absorption and evolution of gas and the transference of heat. An automatic valve is provided to maintain the level of the liquid in a dome at the top of the gas-effusion tube and to regulate the flow of exhausted liquid from the high to the low pressure zone, a reservoir is provided to form a store of recuperated liquid, and a pump to return this liquid to the evolution chamber.

—B. M. V.

Refrigerating apparatus. C. H. Worthen, Beaver, Pa., Assignor to E. E. Worthen, Wellsburg, W. Va. U.S. Pat. 1,332,703, 2.3.20. Appl., 19.2.17.

LIQUID anhydrous ammonia expands through a nozzle at the lower part of an expansion coil; the mixed vapour and unevaporated liquid are led from the upper part of the coil to a separation chamber, whence the residual liquid passes down a pipe jacketing the pipe which supplies the original liquid ammonia, the latter being thus chilled; the residual liquid ammonia is drawn into the expansion coil at the nozzle together with the fresh liquid ammonia.—B. M. V.

Rings for filling absorption towers, distillation columns, or the like. R. Lessing, London. Eng. Pat. 139,880, 27.2.19. (Appl. 4967/19.)

EACH ring is provided with a diametrical partition which may extend the whole or only part of the way across, but must not be joined to the ring in such a way as to interfere with the flow of liquid when the ring is in a horizontal position.—W. H. C.

Filling material for absorption and reaction towers. Prym and Co., Buisbach. Ger. Pat. 317,166, 11.2.18.

THE filling is in the form of tubes made by bending sheet metal. One end of the tube is turned inwards so as to increase the surface, but not the length or diameter. The inner projection, which may be also welded or soldered on, may be corrugated or even worked into the form of a tube.—H. J. H.

Furnace; Producer gas —. C. K. E. Bildt, Norrviken, Sweden. Eng. Pat. 139,957, 22.5.19. (Appl. 12,923/19.)

FOR heating boilers etc. with solid fuel a small proportion of air is admitted through the fuel bed in a separate furnace, thus forming producer gas, and combustion is then completed by secondary air. To prevent the harmful effects on the boiler proper of the intense heat of the producer-gas flame, the combustion chamber of the furnace is surrounded by water tubes which lie close to each other and are mostly straight, though some may be bent to form openings for the entrance and exit of gases. The water-boxes in which the tubes are secured should be inaccessible to the flame, and the one next the boiler proper may be annular, thus forming an outlet for the flame.—B. M. V.

Furnace heating; Method of —. W. E. Renner, Somerville, Mass. U.S. Pat. 1,332,681, 2.3.20. Appl., 30.7.19.

A LARGE part of the gaseous contents of a furnace is allowed to circulate through a conduit leading from the furnace, past jets for supplying additional air and atomised combustible mixture, then back to the furnace. The jets are so inclined as to promote the circulation, the combustible mixture being supplied just before the gases re-enter the furnace.

—B. M. V.

Rotary furnaces; Composite lining for —. W. S. Rockwell, Assignor to W. S. Rockwell Co., New York. U.S. Pat. 1,333,313, 9.3.20. Appl., 8.9.19.

THE shell of a rotary furnace is lined with refractory material and a spiral metallic rib, formed in sections, projects through the lining from the shell into the inner cylindrical space and forms a feeding channel therein.—W. H. C.

Gas furnace. G. W. McKee, Rockford, Ill. U.S. Pat. 1,331,309, 23.3.20. Appl., 18.12.17.

FUEL gas is delivered tangentially into a row of cylindrical combustion chambers opening at the top into a common horizontal chamber which constitutes the heating zone.—W. F. F.

[Electrically] precipitating suspended material from gases. E. R. Wolcott, Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,331,225, 17.2.20. Appl., 28.5.19.

THE material to be deposited is rendered conductive by injecting into the gases a finely-divided solid conducting substance, the latter being deposited with the suspended material.—B. N.

Electrodes of electric precipitators; Arrangement for connecting —. Siemens-Schuckertwerke G.m.b.H., Siemensstadt. Ger. Pat. 314,626, 6.12.18.

THE high-tension electrodes hang vertically from horizontal plates suspended by insulators from the roof of a gas duct. The precipitation electrodes rest on the floor of the duct, and are placed vertically between the high-tension electrodes, so that dead space is reduced to a minimum.—H. J. H.

Electrical precipitator with permeable electrodes. Siemens-Schuckertwerke G.m.b.H., Siemensstadt. Ger. Pat. 314,947, 4.6.18.

THE electrode on which the deposit collects consists of two or more individual electrodes of gauze or the like in electrical connection, but sufficiently widely separated to protect other metallic parts from the electric field. This is done to avoid deposition of material upon other parts such as the supports of the electrodes and the walls of the gas duct.—H. J. H.

Electrical precipitation plant; Process for removal of dust from the settling surfaces of —. H. Pünig, Münster. Ger. Pat. 315,531, 28.10.17.

By means of a whistle, syren, or similar appliance sound waves are set up in the precipitation chambers with sufficient intensity to dislodge the dust which has settled out upon the surfaces.—H. J. H.

Evaporating and crystallising apparatus especially adapted for obtaining large crystals. C. Prache, Paris. U.S. Pat. 1,331,373, 17.2.20. Appl., 29.12.17.

THE apparatus comprises a vertical receptacle, 2, which is constricted in its lower part, 3, in which the crystals are separated. The solution is circulated downwards through the pipe, 12, by a forcing device in the space, 13, and passes through a heater, 9, into the pipe, 16, from which it is delivered at the outlet, 1. The small crystals in the space, 3, are thus suspended in the boiling solution until they grow to a predetermined size, when they fall into the space, 4.

—W. F. F.

Evaporator. C. F. Braun, San Francisco, Cal. U.S. Pat. 1,331,014, 16.3.20. Appl., 4.9.18.

THE evaporator is heated by a system of steam coils which are connected at one end to a supply and at the other to an exhaust manifold formed one on each side of a door that serves to close the opening through which the coils are introduced.—W. H. C.

Dryer and evaporator. C. Offenhauser, Philadelphia, Pa. U.S. Pat. 1,333,871, 16.3.20. Appl., 15.2.19.

A HORIZONTAL cylindrical drying drum is supported at its two ends which project through the two ends of an outer drum. The ends of the outer drum are attached to the inner drum, but means are provided for rotating the cylindrical shell of the outer drum. Hot gas is passed through the space between the drums to heat the inner drum, and an exhaust opening is provided in the upper part of one of the ends of the outer drum.—W. F. F.

Drying liquids; Apparatus for —. O. S. Sleeper, Assignor to Buffalo Foundry and Machine Co., Buffalo, N.Y. U.S. Pat. 1,331,389, 17.2.20. Appl., 25.4.16.

A DRYING drum, supported in horizontal bearings,

dips into the liquid to be dried, which is contained in a pan. The end walls of the pan are in contact with the drum, and the front and rear walls of the pan are adjustable vertically so that they may be in contact with the cylindrical wall of the drum. The liquid is circulated through a pipe, the inlet of which is in the bottom of the pan and the outlet at the top, close to the periphery of the drum.—W. F. F.

Dryer. L. R. Christie, Pittsburgh, Pa. U.S. Pat. 1,332,380, 2.3.20. Appl., 6.1.19.

THE dryer consists of a rotary drum having an outer and an inner shell. The heating gases pass through the inner shell, and the material to be dried passes through the annular space between the shells. Means are provided in the annular space for lifting the material and depositing it on the outer surface of the inner shell.—W. H. C.

Dryer. B. R. Andrews, Braintree, Mass. U.S. Pat. 1,322,657, 2.3.20. Appl., 25.1.18.

THE material is supported on trays which extend transversely across a drying tunnel. The tunnel is provided with baffles on opposite sides to cause the current of air which is passed through it to take a circuitous course. Means are provided to prevent the current of air from passing through any space left between the edge of the baffles and the material.—W. H. C.

Drying process and apparatus. F. P. Boland, Providence, R.I. U.S. Pat. 1,332,506, 2.3.20. Appl., 15.1.19.

A DRYING medium such as air is passed in succession through a small heated area and twice through the material to be dried.—B. M. V.

Dryer; Centrifugal —. G. H. Elmore, Swarthmore, Pa. U.S. Pat. 1,334,023, 16.3.20. Appl., 7.10.16.

A ROTARY annular screen mounted on a vertical shaft is cleaned by means of internal scrapers which are mounted to rotate coaxially with the screen. The scrapers are periodically and automatically moved towards and away from the screen, but out of contact with it.—W. F. F.

Filter-press. A. L. Bausman, Chicopee, Mass., Assignor to National Equipment Co., Springfield, Mass. U.S. Pat. 1,331,453, 17.2.20. Appl., 2.10.18.

THE filter-plates are pressed together by means of a hydraulic plunger, the face of which abuts against a filter-plate. A filtering cloth is arranged on the outside face of each plate, and is pressed against the plate by a collecting ring. A plunger ring surrounds and protects the edges of the cloth, and a packing is provided between the plunger ring and the plunger plate which is independent of the filtering cloth. A spacing device is provided between an abutment on the plunger plate and the plunger ring by means of which the plunger may be allowed to enter the plunger ring and press against the collecting ring to effect filtration or may be prevented from doing so.—W. F. F.

Filter-press device. G. F. Miller, New York. U.S. Pat. 1,333,869, 16.3.20. Appl., 7.6.19.

A FILTER-PRESS frame is provided with recesses in its two faces into which removable members carrying the filter cloths are fitted.—W. F. F.

Bag-filter. E. W. Deming, New York. U.S. Pat. 1,331,692, 23.3.20. Appl., 2.11.16.

THE filter is formed as an open-ended tubular member, and means are provided for supplying the liquid to be filtered, a washing liquid, and a gas, to both ends of the filter.—W. F. F.

Cooling apparatus [for gases]. I. Hechenbleikner, Assignor to Chemical Construction Co., Charlotte, N.C. U.S. Pat. 1,331,500, 24.2.20. Appl., 17.10.18.

AN apparatus for cooling gas comprises a vertical cylinder containing the gas, which is inserted into the open top of a surrounding tube which is closed at the bottom and which is of slightly larger diameter than the cylinder. The cooling liquid is supplied by means of a central vertical tube passing downwards through the cylinder and having its outlet near the closed bottom of the outer tube, so that the cooling liquid passes upwards around the cylinder and overflows at the upper end of the outer tube.—W. F. F.

Centrifugal machine. T. A. Bryson, Troy, N.Y., Assignor to Tolhurst Machine Works. U.S. Pat. 1,331,692, 24.2.20. Appl., 31.12.17.

A CENTRIFUGAL basket open at the top is surrounded by a casing which receives the liquid, and is provided with a bottom closure extending inwards to meet the perforated bottom of the basket. The top of the casing is closed by movable lids, and means are provided for heating the space within the casing.—W. F. F.

Centrifugal separators; Means for controlling the proportion of liquids separated in —. A. J. E. Munters, Assignor to Aktiebolaget Pump-Separator, Stockholm, Sweden. U.S. Pat. 1,331,779, 24.2.20. Appl., 21.12.18.

THE drum of the separator rotates on a vertical axis, and an outlet slot is provided in the neck of the apparatus which projects upwards, and is surrounded by a ring having a peripheral recess co-operating with the slot.—W. F. F.

Impact-pulveriser; Rotary —. C. J. Tomlinson, West Allis, Wis., Assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. U.S. Pat. 1,331,969, 24.2.20. Appl., 23.12.15.

A PAIR of rotors are arranged in a casing and are provided with peripheral projections which impact upon one another during rotation. Means are provided for feeding the material first to one of the rotors only, and then to the space between the co-operating impact surfaces.—W. F. F.

Comminuting-machine. O. Kutsche, Pittsburg, Pa. U.S. Pat. 1,332,220, 2.3.20. Appl., 12.9.18. Renewed 7.7.19.

THE material is crushed by grinding balls in a race or chamber supported by a rotating shell, the balls being kept in position by fixed means carried from above by an outer dust-proof casing.—W. H. C.

Comminuting apparatus. O. Kutsche, Pittsburgh, Pa. U.S. Pat. 1,332,850, 2.3.20. Appl., 10.10.16. Renewed 18.7.18.

A ROTATING base is provided with balls having a contour to fit the base. Material to be ground is fed to the centre of the base, and air under pressure is introduced simultaneously, while the ground material is removed at a lower pressure.—A. E. D.

Pulverising mill. G. F. Hurt, New York. U.S. Pat. 1,334,701, 23.3.20. Appl., 31.5.17.

THE bottom of the grinding chamber is formed as a hollow neck extending upwards into the chamber, and a driving shaft extends upwards through the neck, with an annular space between. The shaft carries revolving grinding rollers, co-acting with a fixed grinding ring, and air is circulated through the grinding chamber so as to draw the fine suspended material through the annular passage in the neck and prevent it from collecting on the moving parts of the mill.—W. F. F.

Waste-heat boiler. J. E. Bell, Brooklyn, N.Y., Assignor to The Babcock and Wilcox Co., Bayonne, N.J. U.S. Pat. 1,332,284, 2.3.20. Appl., 3.2.15.

WASTE gases from an industrial furnace are repeatedly passed vertically up and down over the inclined tubes of a water tube boiler set in the waste gas flue, and provided with cross-baffles so that practically all the waste heat is transferred to the boiler. Suction is provided so that at least 2000 lb. of waste gases per hour are provided per square foot of flow area.—A. E. D.

Gaseous compounds; Process of and apparatus for the oxidation and reduction of —. W. Koehler, Cleveland, Ohio. U.S. Pat. 1,332,730, 2.3.20. Appl., 8.10.18.

VARIOUS gases are mixed at a common point (e.g., by converging jets) and their temperature raised at that point (e.g., by an electric arc).—B. M. V.

Percolating and concentrating apparatus. J. U. Lloyd, Cincinnati, Ohio. U.S. Pat. 1,332,908, 9.3.20. Appl., 6.6.18.

FLUID menstruum circulates downward through a percolator and thence by a pipe to the bottom of a concentrator, which is surrounded by a series of jackets adapted to receive either steam or water. The fluid leaves the concentrator at the top and passes into the top of a condenser, from the bottom of which it passes by a pipe back to the top of the percolator.—W. F. F.

Oxidising apparatus [; Comminuting, rabbling, and —]. J. R. MacMillan, Assignor to Niagara Alkali Co., Niagara Falls, N.Y. U.S. Pat. 1,333,327, 9.3.20. Appl., 20.12.18.

AN oxidising chamber having a smooth flat hearth is mounted above and heated by a furnace. A grinding and stirring element carried by a rotating vertical shaft traverses the hearth and grinds the material on it.—W. F. F.

Liquefaction and separation of gas mixtures such as air; Process and apparatus for —. R. Mewes, Berlin. Ger. Pat. 315,511, 5.9.16. Addition to 290,080.

A PORTION of one of the components is withdrawn from the separation chamber or from another suitable part of the apparatus, somewhat compressed, and then returned in countercurrent to the separation chamber. After giving up heat, the gas being treated is expanded with partial liquefaction by being sprayed into the chamber, effecting some cooling here by admixture. The higher-boiling fraction, after passing through such a cycle, is sprayed into the separation chamber at the point where the fresh mixture enters, whilst the lower-boiling fraction is sprayed into the coldest portion of the chamber. From the high-pressure compressor a gas is drawn which is free from water and carbon dioxide.—H. J. H.

Filling containers with a definite quantity of liquefied gas, e.g., sulphur dioxide; Process for —. G. Giemsa, Hamburg. Ger. Pat. 315,659, 23.6.18.

THE container has separate inlet and outlet openings, the latter being furnished with a siphon tube, the lower end of which marks the desired level of the liquid in the container. In this way the necessity for weighing the liquefied gas is avoided, as also the risk of over-filling the vessel.—H. J. H.

Catalysing material. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 140,011, 8.9.19. (Appl. 22,076/19.)

SEE U.S. Pat. 1,299,641 of 1919; this J., 1919, 415 A.

Fibrox (silicon oxycarbide) may be used as a support for other catalysts, e.g., platinum, in addition to nickel.

Heat exchanger, especially for firing installations. L. Honigmann, Aix-la-Chapelle. Ger. Pat. 314,782, 3.7.17.

Mixing and kneading machines. F. Aeschbach A.-G., Aarau, Switzerland. Eng. Pat. 124,743, 20.3.19. (Appl. 7022/19.) Int. Conv., 20.3.18.

Mixing and sifting powdered and granulated substances; Apparatus for —. B. Young, London. Eng. Pat. 139,597, 26.2.19. (Appl. 4765/19.)

Electric precipitators; Device for protecting insulators in —. A. F. Meston, Assignor to Research Corporation, New York. U.S. Pat. 1,332,510, 2.3.20. Appl., 6.3.18.

Furnaces. A. B. Chantraine, Marcinelle, Belgium. Eng. Pat. 18,471, 8.8.14.

SEE Fr. Pat. 475,649 of 1914; this J., 1916, 53.

[Electrically] separating suspended material from gases; Process of — and apparatus therefor. A. Mond, London. From International Precipitation Co., Los Angeles, Cal., U.S.A. Eng. Pat. 136,464, 27.5.19. (Appl. 13,336/19.)

SEE U.S. Pats. 1,329,737 and 1,329,817—8 of 1920; this J., 1920, 257 A.

Electrical separation of substances in suspension in fluids; Apparatus for —. G. Gallot, Paris, and P. Poussin, Pantin, Assignors to Soc. Purification Industrielle des Gaz, Paris. U.S. Pat. 1,332,981, 9.3.20. Appl., 21.5.18.

SEE Eng. Pat. 116,104 of 1918; this J., 1920, 196 A.

Separating [emulsions of] hydrocarbons and water; Process for —. W. A. Brown and F. G. White, Los Angeles, Cal., U.S.A. Eng. Pat. 139,417, 22.8.19. (Appl. 20,689/19.)

SEE U.S. Pat. 1,309,794 of 1919; this J., 1919, 621 A.

Filtering fluids; Devices for —. F. K. and E. F. Atkins, Harrison, N.J., U.S.A. Eng. Pat. 139,991, 8.7.19. (Appl. 17,059/19.)

SEE U.S. Pat. 1,273,127 of 1918; this J., 1918, 566 A.

Drying process and apparatus therefor. F. P. Boland, Providence, R.I., U.S.A. Eng. Pat. 140,145, 31.12.18. (Appl. 21,927/18.)

SEE U.S. Pat. 1,294,035 of 1919; this J., 1919, 282 A.

Evaporator. E. A. Barbet, Assignor to E. Barbet et Fils et Cie., Paris. U.S. Pat. 1,325,461, 16.12.19. Appl., 28.6.15.

SEE Eng. Pat. 22,844 of 1914; this J., 1916, 293.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal dust in steel mills; Explosions of —. L. D. Tracy. Chem. and Met. Eng., 1920, 22, 422—423.

THE use of pulverised coal as fuel may constitute a serious fire or explosion risk if suitable precautions are not adopted. Fans which drive the dust from the storage bins to the furnace should not be stopped before the pipe line has been thoroughly blown out, as a back draught may carry live sparks into the pipes. Contact of the coal dust with hot metal is to be avoided, and accumulation of dust in the building should be prevented, the use of naked lights during cleaning being forbidden.

—W. J. W.

Low-grade fuels; Firing with —. E. Haack. Brennerzeit., 1919, 36, 8429—8430, 8435—8436. Chem. Zentr., 1920, 91, II., 163.

CHIMNEY stacks have usually been erected to deal with high-grade fuels, and do not give sufficient draught where lower qualities are to be burned, although they suffice for the removal of the products of combustion where forced draught is employed. In new construction it is advisable to build chimneys capable of dealing with low-grade fuel. The air supply to the fuel may be assisted by jets of steam or air, the former being simpler. For inducing draught by steam, however, 5–6% of the steam generated by high-grade fuel is consumed as against 1–1.5% for compressed air.—H. J. H.

Lignite; Separation of — into different groups of substances, their characters and behaviour on dry distillation. W. Schneider. Ges. Abhandl. Kenntn. Kohle, 1919, 3, 325—357. Chem. Zentr., 1920, 91, II., 99—101.

LIGNITE from the Riebeck Montan works yielded 15% of its dry substance as "Bitumen A" on extraction with benzene at 70°–75° C. and 8% as "Bitumen B" on subsequent extraction with benzene at 250°–260° C., the residue constituting 77%. The bitumen A was further divided, by extraction with alcohol and ether, into 2% of a dark resinous substance and 13% of true montan wax. Bitumen B somewhat resembled the resin in appearance, being almost black and transparent in thin layers; in composition and solubility, however, it more closely resembled montan wax. It melted indefinitely about 75° C. The composition and properties of all these fractions are given in tables, and also the amounts and characters of the products produced by their dry distillation. Nearly one-half of the total amount of tar (including the major part of the paraffin) yielded by the original lignite was attributable to the montan wax fraction, bitumen B and the residue accounting each for about one-quarter of the total. By repeated extraction of the residue with boiling 5% sodium hydroxide solution 80% (and by a single extraction for 3 hours at 200° C. in an autoclave 84%) was obtained in solution in the form of humic acids precipitable on acidifying the solutions. The residue insoluble in alkalis contained 36% of ash and 0.47% of nitrogen, had a methyl value of 1.7, and yielded 17.2% of tar on distillation. All lignites appear to yield their major part in a soluble form on heating with alkalis, and this part does not contribute appreciably to the production of tar on distillation.—J. H. L.

Oil from compressed oil-gas. J. C. Mansukhani and J. J. Sudborough. J. Indian Inst. Sci., 1918, 2, 73—77.

Gas from a low-grade kerosene oil is compressed for use as an illuminant by the Indian railway companies. A sample of the volatile oil ("hydrocarbon") deposited during the compression yielded about 9% of olefine hydrocarbons, 15.2% of benzene, and 7% of toluene, both of the latter giving nitro compounds of good colour. No paraffin hydrocarbons were present. About 7000 galls. of this oil is produced per month in India.—C. A. M.

Petroleum oils; Rapid determination of sulphur in —. A. W. Christie and C. S. Bisson. J. Ind. Eng. Chem., 1920, 12, 171—172.

ABOUT 0.5 grm. of the oil is burnt in a calorimetric bomb, and the contents of the latter are diluted with water, filtered, and titrated with standard alkali solution. A portion of the solution, equivalent to about 1.5 mgrm. of sulphur, is diluted to 25 c.c., treated with 1 drop of dilute hydrochloric acid and 10 c.c. of 0.8% benzidine hydrochloride solution. The benzidine sulphate is collected, after 15 mins., on an asbestos filter, washed with cold water, then

dissolved in hot water and 1 c.c. of 10% sodium hydroxide solution, the solution diluted to 100 c.c., 5 c.c. of concentrated sulphuric acid added, and the benzidine titrated hot with $N/20$ permanganate solution. A slight excess of the latter should be added, then a slight excess of $N/20$ oxalic acid solution, and the titration completed with permanganate. The number of c.c. of permanganate solution required to oxidise the benzidine is multiplied by 0.041 to give mgrms. of sulphur in the portion of solution taken for the precipitation.—W. P. S.

Aromatic hydrocarbons in petrol; Methods of estimation of —. D. Florentin and H. Vandenberghe. Bull. Soc. Chim., 1920, 27, 204—209.

To 20 c.c. of the petrol, in a flask cooled in ice, nitric acid (sp. gr. 1.5) is added, drop by drop, with shaking, until a brown tint is no longer produced, and the mixture is then left for fifteen minutes. The contents of the flask are poured into a large excess of water and neutralised with sodium hydroxide. By steam distillation small amounts of impurities arising from the oxidation of impurities in the petrol are removed, and then the petrol is decanted. The aqueous solution is extracted twice with light petroleum spirit, and the extracts are added to the decanted petrol, this mixture then being made up to 100 c.c. with more light petroleum spirit. An aliquot portion is evaporated in a small glass dish *in vacuo* over sulphuric acid to constant weight (or very slight constant loss in weight) the residue being the nitro derivative. The weight of this, multiplied by 0.634, gives the weight of benzene. Alternatively an aliquot portion may be heated with titanous chloride for two hours under a reflux condenser, and the residual titanous chloride titrated with a solution of ferric salt (this J., 1920, 224 A). The second method is rapid and exact, and is preferable to the first when the petrol contains any appreciable quantity of high boiling-point fractions. The examination of a number of samples of commercial motor spirit shows that they contain appreciable quantities of benzene hydrocarbons, particularly toluene.—W. G.

Lubricating oils; Control of —. R. Dubrisay. Ann. Falsif., 1920, 13, 25—33.

The general requirements of a good lubricating oil are mentioned, and the limits given in literature and in commercial specifications for various lubricating oils are recorded. An apparatus described previously by the author (this J., 1917, 1123) may be used for determining the viscosity or fluidity of an oil (see also this J., 1918, 499 A; 1919, 4 A).

—W. P. S.

Paraffin wax; Influence of high temperatures on —. H. Burstin and W. Jakubowicz. Petroleum, 1919, 15, 189—192. Chem. Zentr., 1920, 91, 11., 213.

COMMERCIAL paraffin wax, m.p. 51.5°C ., from petroleum, when heated at 150°C . in a drying oven for 70 hours, lost 77.99% in weight and was carbonised. Another sample, m.p. 57°C ., lost 79.44% in 56 hours. Even after 3 hours in the drying oven at 125°C . the loss in weight of a normal paraffin wax was over 5%. When the access of air was prevented the loss in weight on heating at 125°C . was only 0.49% in 22 hours, and the wax remained white. The loss was still less when carbon dioxide was passed over the paraffin wax, and amounted to only 0.11% after 16 hours. In industrial work the distillation of paraffin wax should be conducted under vacuum with the exclusion of atmospheric oxygen as completely as possible.—J. F. B.

Asphalt rock. Kröhnke. See IX.

Carbon black. Neal. See XIII.

Chloroform from coke-oven gas. Dey. See XX.

PATENTS.

Coal washing plant. C. Rogerson, Hamilton, Scotland. Eng. Pat. 139,612, 4.13.19. (Appl. 5286/19.)

COMPLETE separation of the wash water from the "small" is effected by the use of perforated conveyors, one above the other, along which the coal is caused to travel in opposite directions, the coal being subsequently moved along sheets and withdrawn whilst the water flows in the transverse direction. The larger coal from the upper conveyor is transferred at one end to the lower conveyor so that small particles passing through the perforations of the upper conveyor fall on to a bed of larger coal on the lower conveyor.—A. G.

Fuel; Manufacture of — from anthracite duff. C. H. Steel, Kidwelly, Wales. Eng. Pat. 139,977, 12.6.19. (Appl. 11,848/19.)

ANTHRACITE duff is briquetted with 6—16% of pitch, $\frac{1}{2}$ —2% of lime or chalk, and one part in 450,000 of oxalic acid at a pressure of at least 5 tons per sq. in.—A. G.

Fuel; Composite —. G. Vickers and A. Dickson, Whitehaven. From W. Clayton, Toronto, Canada. Eng. Pat. 110,025, 28.10.19. (Appl. 26,395/19.)

THE fuel comprises 20% of coal, coke, or coal dust with 10% charcoal or ground peat, briquetted with a binder consisting of 25% loam, 10% clay, 15% sawdust, 5% sand, 13% linseed or other crude oil, and 2% lime.—A. G.

Lignite; Treating [briquetting] of —. W. Runge, Orange, N.J., Assignor to International Coal Products Corp., Richmond, Va. U.S. Pat. 1,334,170, 16.3.20. Appl., 30.1.19.

LIGNITE is mixed with pitch, the mixture is partially carbonised, and the product is crushed, formed into briquettes, and carbonised.

Briquettes; Method of manufacturing —. C. H. Smith, Short Hills, N.J., Assignor to International Coal Products Corp., Richmond, Va. U.S. Pat. 1,334,180, 16.3.20. Appl., 18.2.18.

FINELY powdered non-coking bituminous coal is mixed with coking coal and pitch in proportions such that the volatile matter is from 11 to 20% of the whole mixture. Briquettes are formed from the mixture and carbonised.—J. W. D.

Drying of fuels with hot gases; Process for preliminary —. A.-G. für Brennstoffvergasung, Saarbrücken. Ger. Pat. 315,621, 29.10.18.

THE hot gases prior to entering the dryer are passed through a layer of readily ignited material which removes contained oxygen. Such a material is dried lignite, which can be placed on a step grate through which the hot gases travel; or a burner with an inadequate supply of primary air may be employed so that the hot gases in traversing the flame are deprived of oxygen.—H. J. H.

Coke-oven and method of operating same. C. E. Lucke, New York. Assignor to L. and A. A. Wilputte, New Rochelle, N.Y. U.S. Pat. 1,332,909, 9.3.20. Appl., 1.3.18.

A REGENERATIVE coke-oven has each of its heating walls formed with a number of vertical flues, all of which are connected at their upper ends by a common horizontal passage. Half of the vertical flues at one end are connected by small openings at their lower ends to a single horizontal channel at the bottom, and the remaining flues are similarly connected to another horizontal channel. Air is alternately supplied to, and waste gas withdrawn from, each of the horizontal channels at the opposite side of the dividing plane of the two sets of flues from that at which the channel is connected to the flues.

—W. F. F.

Pitch; Process for vaporising and gasifying —.

W. Herrmann, Kiel. Ger. Pat. 314,996, 26.11.18.

THE pitch (soft or hard) is melted at a high temperature and atomised by means of sprays into retorts filled with or traversed by hot gases or superheated steam. The particles of pitch are partly vaporised and deposited in a semi-solid condition on the walls of the retort, where they evolve the remainder of their volatile constituents and unite with the coke already there to form a light, porous deposit which is easily detached. No fusion of the coke layer takes place, and, since the quantity of pitch present in the retort at any given time is very small, no frothing over can occur.—J. F. B.

Alum-shale; Utilisation of — as fuel in calcining furnaces.

H. G. V. Rydahl, Skövde, Sweden. Ger. Pat. 315,695, 23.10.17.

THE alum-shale is carried through the furnace on an endless travelling grate and the material to be calcined is carried on an endless travelling conveyor above the grate. The fuel conveyor may run on rollers arranged alternately at different heights, and the two conveyors should travel in opposite directions. This arrangement is designed to prevent the sintering of the alum shale and the formation of lumps.—J. F. B.

Peat; Process for gasifying —. Elektro-Osmose

A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 316,651, 3.11.17.

THE peat is dried by hot air, the air which has become laden with moisture in its passage through the drying room being discharged into the gas producer. In this way the moisture contained in the drying air is utilised for the gasification, and in the production of "semi-water-gas" the quantity of steam required may be reduced.—J. F. B.

Gas producers. L. Fornas, Paris. Eng. Pat.

139,578, 13.2.19. (Appl. 3503/19.) Addition to 123,323.

THE gas-producer described in the chief patent (this J., 1920, 260 A) is modified by providing arrangements for moistening hard, dry fuel.—A. G.

Gas-producers. Poetter G.m.b.H., Düsseldorf. Ger.

Pat. 317,042, 12.7.17.

A MIXTURE of gas and air is blown through the bottom of the hearth, so that the clinker is converted into a molten slag.—J. F. B.

Gas; Apparatus for manufacturing —. W. D.

Wileox, Chicago, Ill. U.S. Pat. 1,332,369, 2.3.20. Appl., 1.4.18.

TWO gas-generating chambers, each having means for the admission of fuel, the withdrawal of ash, and the introduction of air or steam at the lower portion, are separated by a secondary combustion chamber having an inlet for air and an outlet for waste gas. The gas produced in either generator is passed through the upper part of the combustion chamber, thence into the lower part of the other generator and up through the fuel bed before being withdrawn.—W. E. F. P.

By-product condenser. A. Roberts, Evanston,

Assignor to American Coke and Chemical Co., Chicago, Ill. U.S. Pat. 1,333,631, 16.3.20. Appl., 17.4.15. Renewed 7.1.18.

A SERIES of vertical, columnar units has a gas inlet and a gas outlet manifold at the lower and upper ends respectively, and a partition provided with a valve is disposed between the lower end and the gas inlet of each column. By means of a valved spray-nozzle in alinement with the upper end of each vertical unit, a regulated quantity of precipitating medium is delivered into each column; and a connexion is provided above each of the partitions for the delivery of the fractional precipitate.—W. E. F. P.

Gases; Apparatus for cleaning —. F. R. McGee,

Steubenville, Ohio. U.S. Pat. 1,333,325, 9.3.20. Appl., 13.5.18.

GAS to be cleaned passes through the inlet, 10, into the chamber, A, and then passes upwards through the funnel, 31, into the superimposed annular chamber formed between the outer and inner walls, 2 and 6, respectively. A series of separator pipes, 16, project downwards through the double walls, 6, 5, into the inner chamber, B, and each pipe is provided with means for giving the gas a whirling motion. The gas is thus separated into a central core of clean gas which passes into the collecting chamber, B, and a peripheral layer of impure gas which passes through openings in the wall of each pipe into the narrow annular space between the walls, 5, 6. Each of the chambers is provided with collecting means for deposits at the bottom, and the clean gas is withdrawn at the outlet, 9.

—W. F. F.

Exhaust gases of internal combustion engines; Purification of —. Gasmotoren-Fabrik Deutz,

Cöln-Deutz. Ger. Pat. 315,451, 28.9.18.

THE complete separation of moisture from the exhaust gases suffices to render them innocuous without any further treatment to remove carbon dioxide and sulphur dioxide. The water may be removed by chemical means or by freezing.—H. J. H.

Acetylene gas and the like; Solvent for —. H. S.

Smith, New York, and G. O. Curme, jun., Pittsburgh, Pa., Assignors to The Prest-O-Lite Co., Inc., New York. U.S. Pat. 1,332,525, 2.3.20. Appl., 13.8.18.

A SOLVENT for acetylene gas and the like comprises acetone containing an ester of an organic acid, miscible therewith.—A. G.

Gasoline; Process for obtaining — from natural

gas. J. B. Garner, Pittsburgh, and H. C. Cooper, Clarksburg, W. Va., Assignors to Hope Natural Gas Co., Pittsburgh, Pa. U.S. Pat. 1,332,290, 2.3.20. Appl., 8.6.16.

THE gas, under pressure, is treated with an absorbent. By successive distillation under pressure the absorbent is then deprived of its lighter combustible constituents and gasoline content.

—A. E. D.

Asphalt; Manufacture of —. R. R. Rosenbaum,

Assignor to Central Commercial Co., Chicago, Ill. U.S. Pat. 1,332,359, 2.3.20. Appl., 2.4.15. Renewed 29.7.18.

PARAFFIN hydrocarbons are mixed with non-fusible or imperfectly fusible bitumen. Heat is applied to the mixture in a closed vessel, so that the gas evolved produces a high pressure, until a homogeneous melt is obtained.—A. E. D.

Petroleum reduction; Process of —. F. A.

Kormann, New York, Assignor to W. F. Hull, Brooklyn, N.Y. U.S. Pat. 1,332,849, 2.3.20. Appl., 17.7.18.

THE physical properties of petroleum or like hydrocarbon material are altered by absorbing it in a heated absorbent material, and then expelling it by the application of heat.—A. E. D.

Hydrocarbons; Treating —. J. W. Coast, jun.,

Tulsa, Okla., Assignor to The Process Co. U.S. Pat. 1,333,964, 16.3.20. Appl., 5.5.17.

OIL is cracked in a still at 50 lb. pressure and the

vapour therefrom is passed through fine orifices into a body of cooler oil contained in a reservoir. The escaping vapour from the reservoir passes through a reflux condenser before entering the main condenser. The oil continuously leaves the reservoir and passes into the still.—A. E. D.

Lubricating oils from coal tar oils; Manufacture of —. H. Klever, Karlsruhe. Ger. Pats. (a) 301,774, 2.2.15, and (n) 301,776, 27.3.15.

(a) By heating coal tar oils under pressure to about 250°–350° C., if necessary in the presence of catalysts, they are converted into viscous lubricating oils. The increase in viscosity is mainly due to the condensation of bases and phenols of high molecular weight, particularly the bases, and in a minor degree to the condensation and polymerisation of the neutral constituents, such as hydrocarbons. During the process considerable quantities of ammonia and water are formed. Suitable catalysts are fuller's earth, kieselguhr, kaolin, alumina, quartz powder, aluminium, zinc, iron, cadmium and cuprous chlorides. To obtain products of low solidifying point the tar oils are first treated for the removal of the constituents which readily crystallise, for instance, by distilling off the fractions containing these constituents or by prolonged storage at a low temperature and subsequent filtration or centrifugal extraction. (n) The process described under (a) may be carried out in the presence of small quantities of air or oxygen. Pitch oils obtained from coal tar pitch may be treated by this process.—J. F. B.

Lubricating oil and paraffin wax; Production of high-grade viscous — from high-boiling fractions of gas-producer and low-temperature retort tars. Allgem. Ges. für Chemische Industrie, Berlin. Ger. Pat. 310,653, 11.7.17.

The tar fractions of high boiling point, after removal of constituents containing oxygen by washing with aqueous caustic alkali or ethyl or methyl alcohol, are treated with liquid sulphur dioxide, and the resulting solution is separated from the solid paraffin which settles out. From a producer gas coal-tar distillate, b.p. 270°–450° C., a lubricating oil with a viscosity up to 10 at 50° C., sp. gr. 1.03, and a setting point below –20° C. is obtained.—J. F. B.

Tars, particularly oil-tar; Extraction of — and *deresination of the resulting lubricating oils.* Röchlingsche Eisen- und Stahlwerke G.m.b.H., and R. Schröder, Volklingen. Ger. Pat. 315,554, 15.8.18.

THE tar is subjected to distillation up to 200° or 250° C., and is then transferred hot from the retort into a rotating extractor in which it is treated with calcium oxide or other chemicals capable of combining with resin acids; after cooling it is treated with twice its weight of alcohol and stirred for several hours at the ordinary temperature. The extractor consists of a rotating drum in which trough-shaped vessels filled with chemicals are so arranged that the contents of the troughs cannot be emptied during rotation. The alcohol dissolves the so-called resin acids, while the paraffins and asphaltic constituents remain behind; the remainder of the resin acids is combined with calcium oxide. The alcoholic solution of the oil, when subjected to fractional distillation, yields valuable lubricating products.—J. F. B.

Lubricating and drilling machine oil; Substitute for —. K. S. Fuchs, Heppenheim. Ger. Pat. 316,028, 6.7.18.

THE solution of alkali salts of lignic acid obtained as waste liquor in the digestion of straw, maize-cob meal, etc., is precipitated by waste mineral acid or

bisulphate; the gelatinous product is heated at 70°–75° C., and the lignic acid settles out. A 25% solution of the sodium salt of this product gives a brown oily liquid, which is used as such or after emulsification with a little oil.—J. F. B.

Coke; Process and plant for utilising the steam developed in the quenching of —. J. Pintsch A.-G., Berlin, and L. Rodde, Augsburg-Oberhausen. Ger. Pat. 316,114, 2.5.18.

Gas producers or carbonising plants; Furnace grates, more particularly for use with —. J. Wells, Cairo, Egypt. Eng. Pat. 139,731, 19.9.19. (Appl. 23,086/19.)

Waste fuel; Apparatus for recuperation of —. F. Lioud, Assignor to Soc. Le Coke Industriel, St. Etienne, France. U.S. Pat. 1,331,765, 23.3.20. Appl., 15.11.19.

SEE Eng. Pat. 120,932 of 1918; this J., 1919, 672 A.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Distillation of South Indian woods. H. E. Watson, J. J. Sudborough, K. S. D. Dose, and K. U. Rao. J. Indian Inst. Sci., 1918, 2, 107–119.

DETAILS are given of the yields of charcoal, acetic acid, methyl alcohol, and tar obtained by the distillation of 22 species of South Indian woods. Most of the woods gave lower yields than the woods commonly distilled in other countries. *Casuarina equisetifolia* (Forst.) wood, however, gave good yields of acetic acid (4.12 and 4.21%), and methyl alcohol (1.19 and 2.11%).—C. A. M.

PATENTS.

Retort ovens for the distillation of fuels and bituminous ores. E. Hauser, Madrid. Eng. Pat. 125,980, 22.4.19. (Appl. 9970/19.) Int. Conv., 20.4.18.

A VERTICAL retort of the Hawkins and Barton type (Eng. Pat. 5461 of 1890), having side walls which diverge slightly downwards, has a vertical collecting flue adjacent to one of its side walls. The retort communicates with the flue through a number of closely spaced openings inclined upwards and outwards, and the flue is subdivided by fixed transverse partitions which slope downwards and outwards from the retort. Each compartment thus

formed is provided with a valve-controlled discharge pipe through which, as required, air, inert or reducing gas, or steam may be injected at any desired zone. When the retort is constructed of metal its side walls may be extended to the surrounding setting to separate the flues for the distillation and heating gases. The retorts may be formed with internal transverse undulations on their walls to facilitate the descent of the charge.

—W. F. F.

Arc-lamp. G. M. Little, Pittsburgh, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U.S. Pat. 1,333,665, 16.3.20. Appl., 12.11.15.

The electrodes are enclosed in an arcing chamber, and means are provided by which, through the heat of the lamp, the surfaces exposed to the fumes of the arc are covered with a protective coating derived from an amine.—A. R. P.

Catalytic heating apparatus. Soc. Lyonnaise des Réchauds Catalytiques, Camell, Cochet, Gritte et Cie., Lyons, France. Eng. Pat. 140,001, 30.7.19. (Appl. 18,936/19.) Int. Conv. 24.4.19.

III.—TAR AND TAR PRODUCTS.

Phenols; Identification of. — II. J. A. Lyman and E. E. Reid. J. Amer. Chem. Soc., 1920, 42, 615—619. (Compare this J., 1917, 333.)

The melting points of *p*-nitrobenzyl ethers of a number of phenols are given. In the etherification of esters of salicylic acid it is advisable to employ as solvents the respective alcohols from which they are derived, and to avoid excess of alkali; otherwise interchange of the alkyl groups of the alcohol and of the ester takes place to a certain extent (compare Pardee and Reid, this J., 1920, 305A. Also J. C. S., i., 381).—J. K.

Nitro-compounds; Reduction of aromatic — by means of platinum and hydrogen. G. Cusmano. Annali Chim. Appl., 1919, 12, 123—130.

AROMATIC nitro-compounds (*p*-nitro-derivatives of phenol, anisol, and toluene; *o*-nitrotoluene, *m*-nitroaniline) are readily reduced to amines when shaken in ethereal solution with platinum black in an atmosphere of hydrogen, but even when an insufficient quantity of hydrogen for complete reduction is used, the intermediate stages of nitroso- and β -hydroxylamino-derivatives cannot be detected. This is due to the fact that under the experimental conditions the intermediate compounds are reduced more rapidly than the nitro-compounds. By introducing negative substituents into the nitro-compound (nitrobenzoic acids, nitrobenzaldehydes, dinitrobenzenes, dinitrotoluenes) or by effecting reduction in acid solution (*m*-nitroaniline), the decomposition of the intermediate hydroxylamino derivative can be retarded and its formation demonstrated. (Cf. J. C. S., i., 298.) —C. A. M.

Petrol. Florentin and Vandenberghe. See II A.

Pyrrole, indole, and carbazole. Franklin. See XX.

PATENTS.

Coal tar hydrocarbons and other like matters; Fractional distillation plant for. — W. E. Edwards, Wigan. Eng. Pat. 139,263, 28.1.19. (Appl. 2073/19.)

Tar is led from a receiver through two preheaters into two stills arranged in series. In the first preheater, the tar flows up a cylindrical vessel fitted with a worm which serves as a condenser for the vapours generated in the second still, and is then

led to the second preheater in which it flows up a number of vertical tubes heated by the pitch escaping from the second still. Light oils distil from the tar in the first still, and are conveyed to a water condenser; creosote oil and anthracene oil are removed in the second still, and as the vapours pass down the worm of the first preheater, the anthracene oil condenses first and is tapped off at a point about halfway down the worm, whilst the creosote oil, which condenses in the lower half, is drawn off at the bottom. The first still may be heated by the hot gases escaping from the furnace under the second still, and any permanent gas not condensed in the water condenser may be utilised for heating the stills.—L. A. C.

Carbazole; Manufacture or isolation of. — Burt, Boulton and Haywood, Ltd., and F. D. Miles, London. Eng. Pat. 139,931, 19.6.19. (Appl. 15,440/19.)

CRUDE carbazole, or a mixture containing carbazole, is heated with an alkali metal, or an alkali metal oxide or hydroxide, in the presence of an indifferent solvent, e.g., naphthalene, or toluene under pressure, at a temperature below the melting point of the alkali-carbazole. The solvent is subsequently removed, and the alkali-carbazole is decomposed by boiling with water.—L. A. C.

Hydrocarbon; Process for the manufacture of lower-boiling — from higher-boiling hydrocarbon [toluol from xylol]. A. E. Houlehan, Assignor to E. I. du Pont de Nemours and Co., Wilmington, Del. U.S. Pat. 1,331,033, 16.3.20. Appl., 25.5.17.

XYLOL is subjected to the action of anhydrous aluminium chloride whereby toluol is produced and is distilled off continuously.—A. E. D.

Sulphonation and chlorination of aromatic substances. H. N. Morris and Co., Ltd., and H. N. Morris, Manchester. Eng. Pat. 140,007, 5.6.18. (Appl. 21,360/19.)

AN aromatic hydrocarbon and either sulphuric acid or liquid chlorine are led through atomisers into the mixing chamber in the apparatus described in Eng. Pat. 139,234 (this J., 1920, 291A), and the mixed liquids pass through a chamber or series of chambers maintained at the desired temperature, and, in the case of chlorination, containing a catalyst.

—L. A. C.

Sulphonation of hydrocarbons of the aromatic series. L. M. Dennis, Ithaca, N.Y. U.S. Pat. 1,332,203, 2.3.20. Appl., 6.7.17.

β -NAPHTHALENESULPHONIC acid is extracted from the mixture obtained by sulphonating naphthalene with about 75% sulphuric acid, and the solution obtained is cooled.—L. A. C.

Carbazole; Production of high-percentage. — H. Leroux, Assignor to Soc. d'Éclairage, Chauffage, et Force Motrice, Paris. U.S. Pat. 1,318,212, 7.10.19. Appl., 31.10.18.

IV.—COLOURING MATTERS AND DYES.

Vat dyestuffs; Benzidinoquinones and bisquinonyl-benzidines as —. K. Brass and O. Papp. Ber., 1920, 53, 446—462.

BENZIDINE condenses with toluquinone to yield benzidino-toluquinone, $\text{CH}_3\text{C}_6\text{H}_4\text{O}_2\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4\text{NH}_2$, a dark violet powder which cannot be preserved in contact with air, and which dyes cotton in brown shades from a faintly alkaline vat, the colour being, however, due to polymerised products of the dye. Under similar conditions methylanilino-*p*-benzoquinone yields a mixture of much 2-benzidino-5-methylanilinobenzoquinone and little NN'-bis-5-methylanilinobenzoquinonyl-2-benzidine $[\text{CH}_3(\text{C}_6\text{H}_4)\text{N}\cdot\text{C}_6\text{H}_4\text{O}_2\text{NH}\cdot\text{C}_6\text{H}_4]_2$, which have similar tinctorial properties and dye cotton in yellowish-brown shades from a yellow vat. Di-*o*-anisidine and methylanilinobenzoquinone give 2-di-*o*-anisidine-5-methylanilinobenzoquinone, $\text{CH}_3(\text{C}_6\text{H}_4)\text{N}\cdot\text{C}_6\text{H}_4\text{O}_2\text{NH}\cdot\text{C}_6\text{H}_3(\text{OCH}_3)\cdot\text{C}_6\text{H}_3(\text{OCH}_3)\text{NH}_2$, m.p. 124°—128° C. (decomp.) after softening from 120° C., and NN'-bis-5-methylanilinobenzoquinonyl-2-dianisidine $[\text{CH}_3(\text{C}_6\text{H}_4)\text{N}\cdot\text{C}_6\text{H}_4\text{O}_2\text{NH}\cdot\text{C}_6\text{H}_3(\text{OCH}_3)]_2$, m.p. 244°—246° C., which, on cotton, yield brownish shades with a tendency towards olive. NN'-Bis- α -naphthoquinonyl-2-dianisidine $[\text{C}_{10}\text{H}_7\text{O}_2\text{NH}\cdot\text{C}_6\text{H}_3(\text{OCH}_3)]_2$, brownish-violet crystalline powder, m.p. 303°—305° C., which dyes cotton in violet shades, is prepared from α -naphthoquinone and dianisidine, whilst NN'-bis-3-chloro- α -naphthoquinonyldianisidine, red needles, m.p. 270°—272° C., giving brownish-violet shades on cotton, is similarly derived from 2,3-dichloro- α -naphthoquinone. α -Ethoxybenzidine and α -naphthoquinone yield NN'-bis- α -naphthoquinonyl-3-ethoxybenzidine, $\text{C}_{10}\text{H}_7\text{O}_2\text{NH}\cdot\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5)\cdot\text{C}_6\text{H}_4\text{NH}\cdot\text{C}_{10}\text{H}_7\text{O}_2$, violet-brown needles, m.p. 279°—281° C., which gives violet shades on cotton. 2-Anilino-3,5,6-trichlorobenzoquinone is oxidised by manganese dioxide in the presence of sulphuric acid to 3-anilino-2',5',3',5',6-pentachlorodibenzoquinonylaniline, $\text{C}_6\text{O}_2\text{Cl}_3\cdot\text{N}(\text{C}_6\text{H}_4)\cdot\text{C}_6\text{O}_2\text{Cl}_3\cdot\text{NHC}_6\text{H}_5$, bluish-grey leaflets, which do not melt below 300° C., and which dye cotton in dull brown shades. (Cf. J. C. S., i., 398.)—H. W.

Hæmatoxylin; Preparation of —. P. A. Houseman and C. K. Swift. J. Ind. Eng. Chem., 1920, 12, 173—174.

CRUSHED logwood extract, free from dust, is placed in a cylindrical vessel fitted with a reflux condenser; ether vapour from a flask passes into the top of the cylinder, is condensed, and falls on to the contents of the cylinder; the ethereal extract siphons continuously back into the flask. The latter is heated electrically; a mercury manometer on the flask is in circuit with a relay which cuts off the current if pressure develops in the apparatus owing to incomplete condensation of the ether. When the extraction is finished a tap on the siphon is closed and the ether distilled from the flask into the cylinder. The residue of crude hæmatoxylin in the flask is dissolved in hot water and the solution filtered; pure hæmatoxylin crystallises out as the solution cools.

—W. P. S.

Pyrrole Blacks. A. Angeli and C. Lutri. Atti R. Accad. Lincei, 1920, 29, i., 14—22. (Compare this J., 1919, 139 A.)

IN presence of water or in alcoholic, ethereal, or moist benzene solution, pyrrole and quinone react, giving a black, amorphous compound, which closely resembles Pyrrole Blacks and melanins, and is apparently formed by the interaction of 3 (or 4) mols. of pyrrole and 5 (or 7) mols. of quinone. Under similar conditions indole does not react with pyrrole, but the latter (1 mol.) and 1,4-naphthoquinone (3 mols.) yield a compound crystallising in violet-

black needles. Isatin and pyrrole also react readily. Oxidation of pyrrole by means of hydrogen peroxide yields a Pyrrole Black and a compound, $\text{C}_8\text{H}_{10}\text{ON}_2$, which crystallises in almost colourless needles, m.p. 136° C. (Cf. J. C. S., i., 397.)—T. H. P.

Picric acid. Marqueyrol and Carré. See XXII.

PATENTS.

Disazo dyestuffs; Manufacture of new yellow —. G. B. Ellis, London. From Chemical Works, formerly Sandoz, Basle, Switzerland. Eng. Pat. 132,995, 1.5.19. (Appl. 10,887/19.)

TETRAZOTISED 4,4'-diaminodiphenyl-2,2'-dicarboxylic acid is combined with *o*-hydroxycarboxylic acids of the benzene series, e.g., salicylic acid, 4-hydroxyisophthalic acid, or *o*- or *m*-cresotic acid. The products give yellow shades when printed on cotton with chromium or chromium-aluminium mordants.

Azo dyes; Production of —. J. L. Kane, Philadelphia, Pa. U.S. Pat. 1,333,807, 16.3.20. Appl. 19.6.19.

As an improvement in the production of azo dyes, an aromatic amino is treated with a starchy material in aqueous suspension.—L. A. C.

Azo dyestuffs dyeing mordanted goods. H. Fritzsche, Assignor to Society of Chemical Industry in Basle, Switzerland. U.S. Pat. 1,325,841, 23.12.19. Appl., 14.12.18.

SEE Eng. Pat. 126,460 of 1918; this J., 1919, 457 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

[Wool.] *Causes of the so-called "Allwörden's reaction."* P. Kraiss and P. Wentig. Neue Faserstoffe, 1919, 1, 265—266. Chem. Zentr., 1920, 91, H., 209. (See this J., 1916, 416; 1917, 706.)

ALLWÖRDEN'S reaction does not give uniform results with all kinds of wool and different sections of the same wool fibre behave differently. The chlorine water must be freshly prepared; with bromine water the swellings separate better from the fibre. The removal of suint and grease is important. Hairs containing a medullah may show the reaction very distinctly; feathers do not react. Both in the chlorine reaction which causes the formation of the swellings and in the treatment with alkali which removes the "elastium" from the wool, there is an attack on the protein matters of the wool. The substance sensitive to chlorine is a protein present in the fibrillie layer or in a cementing substance adhering to the fibrillie. At high temperatures the sensitiveness of the test to the influence of alkalis increases to an extraordinary degree, so that at the boiling temperature the traces of alkali which are dissolved from an ordinary glass vessel are sufficient to cause the absence of the reaction. The effect of boiling, however, is entirely suppressed by traces of acid, and the reaction remains positive after an acid treatment which would certainly have an injurious effect on the quality of the wool.—J. F. B.

Fibres and yarns, especially artificial silk and staple-fibre; Tensile strength of —. P. Kraiss. Neue Faserstoffe, 1919, 1, 266—268. Chem. Zentr., 1920, 91, H., 208. (See also this J., 1919, 895 A.)

STAPLE-FIBRE YARNS from viscose or cuprammonium silks show a loss of tensile strength on damping with water, also with spinning emulsions, but petroleum, amyl acetate, and phthalic acid esters impart a distinct increase in strength. Heating for a short time increases the strength in the dry condition,

but the strength in the wet condition is not improved. As regards chemical after-treatments, dyeing with chrome yellow has a favourable effect on viscose yarns, and cuprammonium yarns are improved both by chrome yellow and by treatment with tannin-gelatin. Chemical after-treatments may also mitigate the tendering of artificial silks on damping.—J. F. B.

Straw and wood pulp manufacture; Utilisation of spent liquors from —. M. Müller. *Wochenbl. Papierfab.*, 1919, 50, 2749–2750. *Chem. Zentr.*, 1920, 91, 11., 151.

STEAM is admitted to the digester freshly charged with wood in order to create a vacuum. The whole of the hot, black, spent liquor from a previous digestion is then pumped on to the prepared charge, after which the spent liquor is quickly forced out again by steam free from air. In this way the most important feature of Ungerer's process is utilised. At the end of the digestion, in the manufacture of pulp for bleaching, carbon dioxide and atmospheric oxygen must, as far as possible, be excluded from the digested pulp, for which reason blowing out the charge is preferable to extraction by Shank's process. The freshly blown-out pulp should be treated with hot fresh caustic liquor, which is drained off and used for digesting fresh wood. The destructive action of the liquor on the cellulose may be avoided by using the process described in Ger. Pat. 284,681 (this J., 1915, 1048).

—J. F. B.

Cellulose mucilage. C. G. Schwalbe and E. Becker. *Z. angew. Chem.*, 1920, 33, 57–58.

THE parchment ("pergamyn") cellulose mentioned in a previous paper (this J., 1919, 858 A; 1920, 58 A) had a high methyl value indicating that the treatment had left considerable quantities of lignin unattacked. The physical properties of a number of cellulose mucilages were investigated; that from cotton wool was almost entirely free from fibres exhibiting structure, but some of the parchment cellulose mucilages contained fibre débris. In the case of mucilage prepared from soda- or sulphite-cellulose by grinding in an edge-runner, the Schopper-Riegler sieve apparatus is useless for determining the degree to which the fibre has been converted into mucilage, but the apparatus gave more trustworthy results with mucilage prepared by prolonged beating in the hollander.—W. P. S.

Cellulose mucilage. Hygroscopic properties of paper containing mucilage. C. G. Schwalbe and E. Becker. *Z. angew. Chem.*, 1920, 33, 58–59.

PARCHMENT ("pergamyn") cellulose and parchmentised paper and similar products have a moisture content of 6–8% after exposure to the ordinary atmosphere, but after exposure for four hours in air saturated with water vapour the water content increases to 17–26%. Previous heating at 120° C. diminishes this property of absorbing water.

—W. P. S.

Lignin; Researches on —. II. *Potash fusion of the lignosulphonic acids.* M. Hönig and W. Fuchs. *Monatsh.*, 1919, 40, 341–349.

THE removal of the sulphonic groups from the barium salts previously described (this J., 1918, 502 A) by fusion with caustic potash is only complete at 250°–300° C. In each case protocatechuic acid was the sole phenolic product obtained (compare Melander, this J., 1919, 625 A), the yield corresponding to 13–19% of the purely organic portion of the original material. The sulphonic acids are therefore complicated aromatic sulphonic acids, containing the carbon-skeleton of protocatechuic acid. (*Cf.* J. C. S., i., 291.)—J. K.

Paper; Testing tearing resistance of —. C. F. Sammet. *Paper*, 1920, 25, 1053–1054.

THE Schopper tensile testing machine may be modified so as to afford a numerical value for the resistance to tearing. The lever arm is raised to a definite position up the scale, and a strip of paper, about 6 in. long and 1½ in. wide, is slit at one end to a depth of 2 in. One of the slit ends is then clamped in the upper jaw and the adjacent slit end in the lower jaw of the machine, and the strip is brought to a taut condition by adjusting the hand wheel and starting a tear in the paper of about ¼ in. The lever arm is then released from its fixed position and exerts a tearing force on the paper which decreases as the lever falls. The lever arm comes to rest at the point on the scale where the resistance of the paper balances the weight of the falling arm. The results are concordant, and practical working values are obtained from an average of five tests in each direction of the web. The tearing resistance of machine-made papers is slightly higher across the web than along the web.—J. F. B.

Glucosides. Karrer. *See* XX.

PATENTS.

Broom fibres; Process for improving —. Nessel-anbau-Ges.m.b.H., Berlin. Ger. Pat. 315,754, 10.9.18.

BROOM fibres are treated with strong caustic soda solution or substances with similar action, e.g., sodium sulphide, aluminate, and zincate. The fibres are thereby strengthened; they become curly, more elastic, and softer, and a good spinning material is obtained.—J. F. B.

Paper yarns and textiles; Process for softening —. C. Bennert, Grünau. Ger. Pat. 315,834, 6.3.18.

THE material is treated with the decomposition products of proteins, such as protalbinic and lysalbinic acids or their salts, alone or in conjunction with other suitable substances. When these substances are added to the dyebaths in which cellulose textiles are to be dyed, they promote the absorption of the dyestuff and give more brilliant shades.—J. F. B.

Straw and similar stem and bast fibres; Manufacture of a spinning and weaving fibre from —. Geraer Jute-Spinnerei und Weberei A.-G., Triebes. Ger. Pat. 316,109, 14.5.18.

THE raw material is boiled with a solution of 4–15% of sulphides or polysulphides of alkalis or alkaline earths to which caustic soda is added in the proportion of 1 to 4, until the pectin and lignin matters and the silica are dissolved; the digested mass is then resolved into separate fibres by the force of hot or boiling water directed in the manner of a waterfall upon it, being at the same time washed free from sulphides. In order to avoid hardening during drying, the mass, immediately after the treatment with water, is further treated with dilute aqueous hydrochloric acid, then thoroughly washed and dried.—J. F. B.

Fibres [peat moss]; Process for converting short, brittle — into a condition suitable for spinning. H. Deelen, Amersfoort, Holland. Ger. Pat. 316,511, 22.2.18.

PEAT or peat moss, previously freed from impurities, is treated with a dilute solution of soap or emulsion of fat in such a way that the individual fibres are penetrated by the fatty matter, and the production of a pasty, sticky mass is avoided. The impregnation may take place during the separation of the impurities by shaking or other mechanical treatment of the fibrous material, or else after it has been washed. Yarns can be spun from the treated peat or peat moss, which do not shrink under the

influence of air and moisture, and which are extremely soft and pliable, suitable for weaving in conjunction with stronger materials, such as wool, cotton, or jute.—J. F. B.

Waterproofing fabrics of all kinds. Badische Anilin- und Sodafabrik, Ludwigshafen. Ger. Pat. 303,390, 2.8.17.

THE fabrics are treated with emulsions of crude paraffin and alkaline substances. Crude paraffin, unlike the purified hydrocarbons, readily forms with alkalis emulsions which are stable in the cold. The creosote in the crude paraffin exerts a disinfectant action.—J. H. L.

Paper pulp; Dyeing — with insoluble artificial colouring matters. Farbw. vorm. Meister, Lucius, und Brünig, Höchst. Ger. Pat. 316,259, 5.8.17.

THE paper pulp is intimately mixed with the colouring matters converted into a soluble form, or with the soluble components from which the colouring matters are formed, in the presence of a small amount of water. The process is conducted not in the hollander, but in edge-runners, pulping machines, and kneading machines or other appliances which ensure the intimate mixing of the pulp with only small quantities of water.—J. F. B.

Strawboard, paper, and the like containers; Impregnating or saturating — and subsequently draining the same. J. Spicer and Sons, Ltd., London. From A. E. Shirlow, Glen Huntly, Victoria. Eng. Pats. 139,533 and 139,534, 1.11.18. (Appls. 17,902 and 17,906/18.)

Paper-pulp; Separator for —. J. White, Edinburgh. U.S. Pat. 1,333,287, 9.3.20. Appl., 22.3.19.

SEE Eng. Pat. 131,418 of 1918; this J., 1919, 759 A.

Parchmentised paper, vulcanised fibre, and the like; Manufacture of —. R. H. Clayton, Manchester, J. Huebner, Cheadle Hulme, and H. E. Williams, Assignors to The Manchester Oxide Co., Manchester. U.S. Pat. 1,333,465, 9.3.20. Appl., 10.6.19.

Dyeing paper pulp. Ger. Pat. 316,259. See V.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid containing oxides of nitrogen; Rapid decolorisation of strong —. K. Rosenstand-Wöldike. Chem.-Zeit., 1920, 44, 255.

THE addition of peroxides of lead or barium results in the formation of hydrogen peroxide, which oxidises the nitrogen oxides to nitric acid. The lead or barium formed is precipitated as sulphate, which is insoluble in the cold acid. So small an amount as 0.001—0.01% of hydrogen peroxide will effectively decolorise ordinary acid, whilst 1% suffices for an almost black material.—A. E. D.

Sulphuric acid; Gravimetric determination of —. L. W. Winkler. Z. angew. Chem., 1920, 33, 59—60.

Dry barium sulphate evolves a small quantity of sulphuric anhydride when ignited. When sulphuric acid is precipitated from a potassium sulphate solution having an acidity of about N/100, the weight of precipitated barium sulphate (about 0.3 gm.) dried at 130° C. should be multiplied by 1.0045, or that of ignited barium sulphate by 1.0099, in order to obtain the correct weight.—W. P. S.

Nitrogen oxides; Improvements in the industrial production of — in arc furnaces. F. Gros. Comptes rend., 1920, 170, 811—813.

THERE is considerable loss of energy in the fixation of atmospheric nitrogen in electric arc furnaces owing to the humidity of the atmosphere and its relatively low oxygen content. Yields at least 50% higher per kilowatt-hour can be obtained by using dry gases and artificially increasing the oxygen content up to 50%. The nitrogen peroxide can be collected by cooling the issuing gases to low temperatures. The gases circulate in a closed circuit, thus remaining dry, dry oxygen and nitrogen being introduced as required. The nitrogen peroxide collected as above may be converted into nitric acid of any strength required. The heat recoverable from the gases issuing from the furnaces is more than equivalent to the energy necessary for working the cooling apparatus and for the manufacture of the necessary oxygen.—W. G.

Nitrogen; Theoretical study of fixation of — by the electric arc. C. P. Steinmetz. Chem. and Met. Eng., 1920, 22, 299—304, 353—357, 411—416, 455—462.

THE theoretical factors involved in the fixation of nitrogen by the electric arc method have been extensively studied by the author. His investigations include a consideration of the reaction velocities and thermal equilibrium, tables of thermal nitrification constants, reaction periods and velocities in air being given. The influence of the rate of cooling

PATENTS.

Dyeing machine. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,332,188 and (B) 1,332,489, 2.3.20. Appl., 28.9 and 26.10.17.

(A) WITHIN a dyeing chamber are arranged a series of fibre chambers each composed of non-perforated sides, a foraminous bottom plate, and a foraminous top plate which can be moved within the chamber and held in any desired position with respect to the

is illustrated by curves. The employment of multiple arcs, and the cooling of the arc by adiabatic expansion and molecular diffusion, are discussed, as well as the effect of the arc in dissociating N_2 , O_2 , and NO . Finally, the principles of the arc and the characteristics of the various types have been studied and compared.—W. J. W.

Ammonium sulphate; Caking of —. C. G. Atwater and J. F. W. Schulze. *Chem. and Met. Eng.*, 1920, 22, 373—374.

THE caking of certain samples of ammonium sulphate was found to be due to the presence of pyridine sulphate, which causes the material to absorb moisture on damp days, subsequent loss of this on dry days producing a caking effect. Phenols do not cause the phenomenon. By passing dry ammonia gas, preferably preheated, through the sample, or by treatment with very dilute ammonia liquor, pyridine is liberated and the absorption of moisture and caking become inappreciable. (*Cf* this J., 1920, 101 r.)—W. J. W.

Ammonium nitrate; The formaldehyde method for determining —. J. T. Grissom. *J. Ind. Eng. Chem.*, 1920, 12, 172—173.

NEUTRAL 20% formaldehyde solution is added to the ammonium nitrate solution, the mixture heated to 60° C., and titrated with $N/3$ sodium hydroxide solution, using phenolphthalein as indicator. The reaction proceeds according to the equation: $6CH_2O + 4NH_4NO_3 + 4NaOH = C_6H_{12}N_4 + 4NaNO_3 + 10H_2O$. The results are consistently about 0.25% too low.—W. P. S.

Ammonium chloride; Phenomena observed during the melting, freezing, and boiling of mixtures of — and other chlorides. K. Hachmeister. *Z. anorg. Chem.*, 1919, 109, 145—186.

THE inversion temperature of ammonium chloride lies at 174° C. The following melting points are given: cuprous chloride 425° C., lithium chloride 605° C., zinc chloride 283° C., cadmium chloride 568° C., ferric chloride 303° C., thallous chloride 427° C., and lead chloride 501° C. In addition to binary compounds of ammonium chloride with the above named chlorides, already known, the following also exist: $CdCl_2 \cdot NH_4Cl$; $2ZnCl_2 \cdot NH_4Cl$, and $FeCl_3 \cdot NH_4Cl$. The compound $FeCl_3 \cdot NH_4Cl$ possesses a definite boiling point, 386° C. (*Cf* J.C.S., May.)—J. F. S.

Caustic pot settings. F. G. Wheeler. *Chem. and Met. Eng.*, 1920, 22, 372—373.

FOR securing economical working and long life of plant in caustic soda manufacture, a high temperature must be maintained in the furnace, and the ash-pit should hold a small amount of water so that steam passes with the air through the grates and keeps them clinkered. A combustion chamber behind the grate enables the soot to be burned before the hot gases are chilled by the pot, and so reduces smoke. Baffles are placed in the flue to keep the gases close to the pot before escaping up the stack. The life of the pots is increased by protecting them from any blow-torch effect of the flames by means of a guard wall thin enough not to hold the heat or reflect it into the furnace. The pots themselves should be so arranged as to facilitate turning them periodically.—W. J. W.

Nitrates; Effect of chlorides on the nitrometer determination of —. M. T. Sanders. *J. Ind. Eng. Chem.*, 1920, 12, 169—170.

IN the determination of nitric acid in sodium nitrate by means of the nitrometer, it is not possible to obtain results accurate within 0.1% if the nitrate contains more than 15% of its weight of sodium chloride.—W. P. S.

Copper sulphate; Rapid determination of — in works liquors. E. C. Carron. *Ann. Chim. Analyt.*, 1920, 2, 69—71.

THE amount of copper sulphate in the solutions at various stages of the manufacture may be determined with an accuracy within 1% by a simple process of centrifuging. The liquors must not contain more than 20—25 grms. of acid per litre, and the temperature of the mother liquors after centrifuging must not be below 22° C. The average contraction of the liquors after taking the sample is about 4%, whilst the copper sulphate crystals separated by centrifuging have sp. gr. 1.86: Fifty c.c. of hot liquor is measured into each of two copper tubes, which are placed for 15 to 20 mins. in a cold water bath, so as to lower the temperature from 90° to about 35—40° C., and then centrifuged for 3 to 4 mins. The mother liquors from the tubes are then drained into a graduated burette. Their volume deducted from 96 gives the number of c.c. occupied by the crystallised copper sulphate, and the latter value multiplied by 1.86 gives the weight of that salt. The amount of copper sulphate remaining in solution in the mother liquor may be found by determining the temperature of the liquid and referring to a table. At 10° C. the liquor contains 317.6 grms.; at 15° C., 337.1; at 20° C., 356.7; at 25° C., 378.1; and at 30° C., 401.6 grms. per litre.—C. A. M.

Catalysis. VII. Catalysis in heterogeneous systems. N. R. Dhar. *Proc. K. Akad. Wetensch.*, 1920, 22, 570—575.

THE velocity of solution of anhydrous ferric sulphate in water can be increased by the presence of reducing agents such as stannous chloride or ferrous sulphate. When 20% nitric acid in excess acts on copper at 18° C. so that the whole of the copper is dissolved, the action is accelerated by both ferrous and ferric salts as well as by a number of other compounds. Oxidising agents, as hydrogen peroxide, chromic acid, etc., retard the action of the acid. There is a small group of substances which in very small concentration exert a slight accelerating effect, whilst in larger concentrations they have a retarding effect. It is shown that nitrous acid is formed by the action of nitric acid on ferrous salts.—W. G.

Lead chromates. M. Gröger. *Z. anorg. Chem.*, 1919, 109, 226—234.

NORMAL lead chromate is prepared by adding 20 c.c. of $N/1$ potassium chromate to 19 c.c. of $N/1$ lead acetate. If 40 c.c. of $N/1$ lead acetate is treated with 10 c.c. of potassium chromate and the mixture evaporated to dryness on a water bath and washed with water the basic compound, PbO , $PbCrO_4$, is produced. By rubbing 2 grms. of normal lead chromate with 30 c.c. of $N/1$ potassium acetate, evaporating to dryness on a water bath, and washing with water, a lead potassium chromate, $2PbCrO_4 \cdot K_2CrO_4 \cdot H_2O$, is obtained.—J. F. S.

Lead cyanide. N. M. Gupta. *J. Ind. Inst. Sci.*, 1914, 1, 47—48.

THE precipitate formed by the interaction of cyanides and lead salts in aqueous solution is a basic salt, and varies in composition with the concentration of the solutions employed. On boiling a 5% solution of hydrogen cyanide with the precipitated cyanide under a reflux condenser, then filtering the liquid, and allowing it to evaporate in a desiccator, deep yellow needle-shaped crystals of lead cyanide, $Pb(CN)_2$, separated. Lead cyanide is unattacked by concentrated nitric and sulphuric acids in the cold, but on adding water to a crystal the insoluble oxycyanide is formed.—G. F. M.

Magnesium nitride; Behaviour of — towards carbon monoxide and carbon dioxide. F. Fichter and C. Schölly. *Helv. Chim. Acta*, 1920, 3, 298—304.

THE reactions between freshly prepared magnesium nitride and carbon monoxide and carbon dioxide respectively at 1250° C. are expressed by the equations: $\text{— Mg}_3\text{N}_2 + 3\text{CO} = 3\text{MgO} + \text{N}_2 + 3\text{C}$; $\text{— Mg}_3\text{N}_2 + 3\text{CO} = 3\text{MgO} + 3\text{CO} + \text{N}_2$. Carbon monoxide causes no change at 750° C., and reacts less readily than the dioxide. The reactions probably follow upon the dissociation of the nitride, which is almost complete at 1500° C. Aluminium nitride, which dissociates much less readily (Fichter and Oesterheld, this J., 1915, 518), is oxidised by carbon dioxide at 1300° C. to the extent of only 89%. (*Cf.* J.C.S., May.)—J. K.

Gadolinium. Methods of separation of the terbium and ytterbium earths. R. J. Meyer and U. Müller. *Z. anorg. Chem.*, 1919, 109, 1—30.

GADOLINIUM is best obtained from euxenite, samarskite, or monazite residues. When the mixture contains little cerium earths and much yttrium earths the gadolinium is separated with the cerium earths in one operation by the potassium double sulphate method. If the mixture contains much cerium earths the major portion of these is removed by the double nitrate method. In either case a fraction very much richer in gadolinium is obtained. This is converted into bromates and the yttrium earths removed by fractionation; the ytterbium earths first pass into the mother liquors, then follow the erbium earths, and last of all yttrium. It is essential that the yttrium should be entirely removed at this point, for it is hardly possible to separate it at any of the succeeding stages. The main fraction contains samarium, gadolinium, neodymium, terbium, and europium; it is converted into acetate and fractionated, the fractionation being combined with the fractionation of the double bismuth nitrates. The cerium earths are rapidly separated, and a brown mixture of oxides, containing gadolinium and terbium, is obtained. These elements are rapidly separated by fractional precipitation with ammonia. It is possible, by the above method, to obtain pure gadolinium oxide in a few months. (*Cf.* J.C.S., May.)—J. F. S.

Carbonyl chloride. E. Paternò and A. Mazzucchelli. *Gazz. Chim. Ital.*, 1920, 50, 30—53.

THE density of liquid carbonyl chloride between -15.4° and $+59.9^\circ$ C. is $1.4264 - 0.002326 t$, t being in degrees centigrade. The critical temperature is $187^\circ \pm 2^\circ$ C., critical density 0.5135, critical pressure about 51.5 atm., b.p. 8.02° C. at 760 mm. The chloride decomposes in contact with pure water, but its decomposition products, carbon dioxide and hydrochloric acid, retard further action, which is thus dependent on diffusion; acids in general also delay the interaction of water and carbonyl chloride. Besides the ordinary reaction between carbon tetrachloride and fuming sulphuric acid, $\text{CCl}_4 + 2\text{SO}_3 = \text{S}_2\text{O}_7 + \text{COCl}_2$, in presence of excess of the hot fuming acid the reaction, $\text{CCl}_4 + 4\text{SO}_3 = 2\text{S}_2\text{O}_7 + \text{CO}_2$, also takes place. At -15° C. liquid carbonyl chloride absorbs chlorine, giving a liquid containing 28.3% of free chlorine. Carbonyl chloride is absorbed in considerable proportions by heavy lubricating oils, from which it is expelled rapidly and almost completely by a current of air. (*Cf.* J.C.S., May.)—T. H. P.

Liquefied and compressed gases; Purification of — for laboratory purposes. L. Moser. *Z. anorg. Chem.*, 1920, 110, 125—142.

CARBON dioxide, in steel cylinders, is generally 98—99% pure, and may contain small quantities of

oxygen, nitrogen, and carbon monoxide, rarely traces of hydrogen sulphide and sulphur dioxide. It can be completely freed from oxygen by passing at a rate of 1—6 litres per hour through a paste of chromium acetate and then through a 15% solution of titanous chloride acidified with hydrochloric acid, or by passing over red hot copper at 4—10 litres per hour. Copper has no reducing action on carbon dioxide. To free it from traces of carbon monoxide the gas may be passed over asbestos carrying finely divided cuprous oxide at $700^\circ - 800^\circ$ C. Hydrogen sulphide can be removed by passing the gas over pumice stone soaked in copper sulphate solution, and sulphur dioxide by means of acidified 2N permanganate solution. Commercial nitrogen, prepared by the Linde process, has only to be freed from traces of oxygen. The best wet absorbent is copper gauze in ammonium carbonate solution, the gas being subsequently passed through concentrated sulphuric acid to absorb ammonia. It can finally be passed over copper-asbestos heated to $700^\circ - 800^\circ$ C. to absorb the last traces of oxygen. Hydrogen, if prepared electrolytically, is practically free from impurities, but if prepared by the Linde process from water-gas it may contain air, carbon dioxide, carbon monoxide, and sometimes arsine. In many cases the hydrogen is contaminated with iron pentacarbonyl, formed by the action of carbon monoxide on the steel cylinder under pressure. Since it is practically impossible, by chemical means, to free the hydrogen from this impurity or its decomposition products, such samples are unsuitable for laboratory use. Commercial oxygen, prepared by the Linde process, contains only traces of nitrogen, which cannot be removed by chemical means, and a trace of carbon dioxide which can be removed by soda-lime. Electrolytic oxygen may contain up to 4% of hydrogen, which can be removed by passing the gas over heated platinised asbestos and then through sulphuric acid to remove the water formed. Commercial chlorine, which is generally prepared electrolytically, is purified by liquefying the gas from the cylinder in a tube immersed in a carbon dioxide-ether mixture, allowing impurities such as air and carbon monoxide to escape. Sulphur dioxide can be purified in the same way as chlorine, but the gas as supplied is pure enough for most purposes. Commercial ammonia is about 98% pure, the remainder consisting of water and organic substances, such as pyridine, methylamine, pyrrole, etc., which are difficult to remove. It can be dried by means of lime or soda-lime.

—E. H. R.

Nitroglycerin waste acid. Dodds. *See* XXII.

PATENTS.

Sulphuric and haloid acids; Production of —. H. Tobler, Hackensack, N.J., Assignor to American Bromine Co., Maywood, N.J. U.S. Pat. 1,332,581, 2.3.20. Appl. 9.1.19.

SULPHUR dioxide and a halogen are introduced into, and caused to combine in, a stream consisting of a mixture of the acids with water, the haloid acid being then separated by the action of sulphur dioxide alone.—W. J. W.

Nitric acid; Process for producing —. T. F. Banigan, Kenvil, N.J., Assignor to Hercules Powder Co., Wilmington, Del. U.S. Pat. 1,332,195, 2.3.20. Appl. 12.3.19.

A STREAM of a mixture of pulverised nitre-cake and sodium nitrate is subjected to a simultaneous tumbling and progressive movement, the supply end of the stream being kept at a low temperature, and the discharge end at a high temperature. The nitric acid produced is caused to flow in a contrary direction to the stream.—W. J. W.

Ammonia; Synthetic production of —. F. J. Metzger, New York. U.S. Pats. (a) 1,313,314, (b) 1,313,315, and (c) 1,313,316, 19.8.19. Appl., 12.6.18.

(A) High efficiency is attained in the catalytic production of ammonia from nitrogen and hydrogen by periodically changing the temperature during the reaction period in order to restore the catalyst. (B) Synthetic ammonia is produced by bringing a mixture of hydrogen and nitrogen into intimate contact with a fluid catalytic composition consisting of a finely divided catalyst in an organic liquid vehicle, *e.g.*, a finely ground mixture of cerium or cerium alloy and paraffin. (C) An unsaturated organic liquid, *e.g.*, cottonseed oil, is used as or in addition to the organic liquid vehicle specified under (B). The unsaturated substance acts as a "promoter" of catalytic activity.—L. A. C.

Ammonia; Apparatus for the production of synthetic —. R. F. Gardiner, Clarendon, Va. U.S. Pat. 1,333,404, 9.3.20. Appl., 28.5.19.

The apparatus consists of an electrolytic cell of the suction type, packed with a diaphragm of "filtros," "fruit pit," and cotton, saturated with an alkaline solution. (See also U.S. Pat. 1,328,082; this J., 1920, 231 A.)—W. E. F. P.

Ammonia; Process of recovering — by means of sodium bisulphate. G. N. Vis, Paris. U.S. Pat. 1,332,419, 2.3.20. Appl., 25.10.18.

SODIUM bisulphate is treated with ammonia to produce crystallised sodium ammonium sulphate, and the latter is heated with ammonium sulphate solution. The insoluble residue (sodium sulphate) is then removed, and the solution is cooled to produce crystals of ammonium sulphate.—W. E. F. P.

Ammonia coolers; Process and apparatus for the working of —. A. Klönne. Ger. Pat. 314,362, 8.12.17.

FLUCTUATIONS of pressure between the ammonia cooler and the receptacle for condensed liquid, which is connected to the former through an overflow pipé, are equalised, without loss of gas, by means of a device parallel to the overflow pipe. This device consists of an outer cylinder communicating by a pipe with the gas inlet to the cooler, and an inner cylinder communicating by a pipe with the lower part of the cooler and with the overflow pipe. Perforations around the base of the inner cylinder, which are normally covered by a water-seal, enable gas to pass from the outer to the inner cylinder in the event of a pressure difference sufficient to uncover the perforations. Thus whenever the pressure of gas at the inlet to the cooler exceeds a certain value, gas passes directly through the cylinders to the base of the cooler and the overflow pipe.

—J. H. L.

Ammonium bisulphate; Process for producing — from ammonium sulphate. Badische Anilin- und Sodafabrik, Ludwigshafen. Ger. Pat. 315,622, 16.9.17.

NORMAL ammonium sulphate, which can be readily prepared by interaction of ammonium carbonate with natural sulphates, is heated directly by flame gases, preferably rich in steam, and the fused ammonium bisulphate is withdrawn from the hot reaction zone as rapidly as possible.—J. H. L.

Cyanogen compounds; Process of manufacturing —. H. Foersterling, H. Philipp, and R. N. Sargent, Perth Amboy, N.J., Assignors to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,332,439, 2.3.20. Appl., 29.10.13. Renewed 14.1.18.

A VOLATILISABLE metal and nitrogen are brought into contact with excess of charcoal and heated to

about the boiling point of the metal. When the commencement of the reaction is denoted by an appreciable rise in temperature, the extraneous heat is discontinued, and the combination of the elements is allowed to proceed by means of the heat of reaction, most of the cyanogen compound produced being absorbed by the excess of charcoal.—W. J. W.

Alumina; Method for the production of —. B. F. Halvorsen, Christiania. U.S. Pat. 1,333,020, 9.3.20. Appl., 30.10.19.

ALUMINA is produced from solutions of aluminium compounds by heating with ammonia under pressure.—W. J. W.

Hydrosulphite liquors; Preserving — from decomposition. P. MacIntyre, Clinton, Mass. U.S. Pat. 1,333,029, 9.3.20. Appl., 13.8.19.

THE decomposition of hydrosulphite liquors is prevented by keeping them at a sufficiently low temperature and excluding oxidising influences.

—W. J. W.

Titanium compounds from titaniferous material; Process of extracting — and the product obtained thereby. G. Jebesen, Assignor to Titan Co. A./S., Christiania. U.S. Pat. 1,333,819, 16.3.20. Appl., 12.10.17.

FERROTITANIFEROUS material is treated with sulphuric acid, and the resulting slime is heated to produce a solid mass, which is lixiviated to obtain a solution of titanium and iron compounds. The quantity of acid employed is less than that required to form normal salts with the base-forming material present in the resulting solution.—W. E. F. P.

Magnesium carbonate; Process for producing light basic —. "Lipsia" Chem. Fabrik, Mügeln. Ger. Pat. 301,733, 20.2.17.

A SOLUTION of a magnesium salt (*e.g.*, waste salts from the potash industry) is treated with ammonium magnesium carbonate at a temperature not above 55° C., and the magnesium carbonate produced is separated and converted into the basic carbonate by heating with water. A very light normal carbonate is obtained which on boiling with water yields a basic carbonate about twice as voluminous as itself.—J. H. L.

Soda alum; Process for producing —. R. Linkmeyer, Barby. Ger. Pat. 303,981, 21.6.17. Addition to 301,641 (this J., 1920, 64 A).

IN the process of the original patent, water is added to or evaporated from the melt as required, in order to maintain approximately equimolecular proportions of water and bisulphate during the reaction period. The reaction temperature is thereby kept within the required limits, and the melt acquires the right physical characters.—J. H. L.

Nitrous gases; Process for absorbing — in stages. H. Pauling, Berlin-Lichterfelde. Ger. Pat. 306,353, 13.12.17.

THE gases, *e.g.*, as formed by combustion of air, are subjected to counter-current absorption with the absorbent alternately at higher and lower temperatures. The absorbent may be circulated so as to return once in every cycle to a point of minimum temperature; it may be passed over two towers and conducted over a heater in passing from the first to the second tower and over a cooler in passing from the second to the first, so that the gases give up heat to the absorbent in the first tower and withdraw heat therefrom in the second. This arrangement promotes the oxidation of nitric oxide at the higher temperature, and the absorption of the nitrous gases at the lower one.—J. H. L.

Soda; Process for the production of ammonia —. R. Schad, Darmstadt. Ger. Pat. 315,549, 26.4.17.

BEFORE the separation of the bicarbonate from its mother liquor sufficient water is added to dissolve the whole of the ammonium chloride present. The washing and drying of the bicarbonate are thereby facilitated.—J. H. L.

Mercuric oxide; Electrolytic production of — from mercury. Consortium für elektrochem. Industrie G.m.b.H. Ger. Pat. 315,656, 31.3.18.

THE alkaline electrolytic liquor is treated with organic substances possessing the character of protective colloids, e.g., glue, starch, waste liquors from the treatment of wood and cellulose, caramel, dextrin, etc. The current efficiency is thereby increased almost to the theoretical, and the mercuric oxide obtained deposits slowly and can easily be separated, by sedimentation, from metallic mercury.—J. H. L.

Sulphur retort. F. W. Beecraft and A. L. Genter, Salt Lake City, Utah, Assignors to United Filters Corporation, New York. U.S. Pat. 1,332,537, 2.3.20. Appl., 25.2.19.

A HORIZONTAL, rotary cage for containing sulphur ore is enclosed in a casing having a stationary head and a shell portion which is movable lineally with respect to the head.—W. E. F. P.

Sulphur; Process for obtaining — by heating gypsum with reducing agents. F. Weeren, Neukölln. Ger. Pat. 301,712, 30.9.15.

SULPHUR is produced by heating gypsum with reducing agents in presence of silicious fluxes in a blast furnace, the gypsum and the silicious fluxes being introduced into the furnace in lumps. A freely flowing slag is obtained free from sulphuric acid, calcium sulphate, or calcium sulphide.

—J. H. L.

Hydrogen; Apparatus for producing — from steam. K. Zöller, Charlottenburg. Ger. Pat. 300,761, 6.3.17.

IN the production of hydrogen from steam by alternate oxidation and reduction of iron ore or other contact agent, the latter is contained in two or more columns so connected that first one and then the other receives the reducing gases, the excess of which, mixed with air, serves to preheat the alternate column, whilst the steam is conducted in the reverse direction. The contact material is heated directly, the usual superheating being omitted.

—J. H. L.

Hydrogen; Process for producing — from hydrocarbons and steam. Badische Anilin- und Soda-Fabrik, Ludwigshafen. Ger. Pat. 306,301, 21.8.14. Addition to 296,866.

IN the production of hydrogen from hydrocarbons and steam at high temperatures by means of nickel as catalyst, the steam is partially or entirely replaced by carbon dioxide. The reaction, $\text{CH}_4 + \text{CO}_2 = 2\text{CO} + 2\text{H}_2$, takes place to an extent which increases with rise in temperature and in the concentration of carbon dioxide. A second reaction, however, $\text{CH}_4 + 3\text{CO}_2 = 4\text{CO} + 2\text{H}_2\text{O}$, is usually the predominant one, but the products can be converted into carbon dioxide and hydrogen by subsequent treatment with a suitable catalyst at lower temperatures.—J. H. L.

Chlorides; Preparation of anhydrous metallic —. P. L. Hulin, Grenoble, France. Eng. Pat. 140,114, 7.5.18. (Appl. 7661/18.) Addition to 128,327.

SEE U.S. Pat. 1,304,567 of 1919; this J., 1919, 630 A.

Barium hydroxide; Process for preparing — from barium sulphide. E. A. Barnes, Allentown, Pa., U.S.A. Eng. Pat. 140,297, 18.7.19. (Appl. 17,991/19.)

SEE U.S. Pat. 1,316,133 of 1919; this J., 1919, 819 A.

Ammonia; Synthetic production of —. G. Claude, Assignor to L'Air Liquide (Soc. Anon. pour l'Étude et l'Exploit. des Proc. G. Claude), Paris. U.S. Pat. 1,332,460, 2.3.20. Appl., 14.3.18.

SEE Eng. Pat. 130,086 of 1918; this J., 1919, 718 A.

Ammonium nitrate; Manufacture of —. J. R. Partington, Lostock Gralam, and G. J. Jones, London. U.S. Pat. 1,306,924, 17.6.19. Appl., 10.12.18.

VIII.—GLASS; CERAMICS.

Striae in optical glass; Comparison tests for — by the Brashear converging light, direct view, Bureau of Standards' tank immersion, and short range projection methods. L. E. Dodd. J. Amer. Ceram. Soc., 1919, 2, 977—1006.

THE author determined the number of striae in 117 samples of glass by each of the four methods mentioned in the title and found that, when the samples have polished ends, the short range projection method is the best for regular use. A beam of light is projected from a small lamp of special shape, giving a line of light 2.4 mm. long and 0.5 mm. wide, through the glass to be examined on to a sheet of plate glass with an opal backing. Shadows of any striae in the specimen are projected on to the screen.—A. B. S.

Cristobalite; Latent heat of fusion of —. E. W. Washburn. J. Amer. Ceram. Soc., 1919, 2, 1007—1008.

THE latent heat of fusion of cristobalite in binary mixtures of silica and alumina, very rich in silica, calculated from the lowering of the freezing point, is found to be 6950 cal. per mol. if the solute is sillimanite, or 6650 cal. per mol. if it is alumina. The weighted average of these results is 6800 cal. per mol. or 110 cal. per gram. If the

solute consists of associated molecules the calculated latent heat of fusion will be too large. (Cf. J. C. S., May.)—A. B. S.

Enamel-lined apparatus; Manufacture of —. E. P. Poste. J. Amer. Ceram. Soc., 1919, 2, 944—976.

A DETAILED, illustrated description of one of the customary methods of enamelling steel and cast iron, including recipes for enamels, method of fritting, grinding, applying and burning the enamel. The use of the microscope in studying the effect of over- or under-firing is recommended.

—A. B. S.

PATENTS.

Kiln [; Ceramic —]. R. C. Purdy, Worcester, Mass., Assignor to Norton Co. U.S. Pat. 1,332,471, 2.3.20. Appl., 15.6.18.

A CIRCULAR kiln with several inlet flues beneath the floor has fire-boxes opening into the flues, a baffle wall or bag wherein the gases from the fire-boxes and flues are mixed, a conduit from the mixing chamber to the exterior of the heating chamber of the kiln, and means for removing the gases from the latter.—A. B. S.

Tunnel kiln. G. W. Booth, Islington, Ontario. U.S. Pat. 1,333,099, 9.3.20. Appl., 17.5.19.

A TUNNEL kiln has, in its walls, an air space extending longitudinally through the kiln. At one end of the firing zone is a furnace and at the other end a chimney stack both communicating with the interior of the kiln. A flue in the lower part of the tunnel communicates at one end with the stack and with the aforesaid air space at the other end.—A. B. S.

Carboys or large glass containers; Making —. H. M. Brown, Assignor to Spring Stopper Co., Brooklyn, N.Y. U.S. Pats. 1,334,647—8, 23.3.20. Appl., 2.12.18 and 28.2.19.

IX.—BUILDING MATERIALS.

Cement; Effect of calcium sulphate on —. J. C. Witt. Philippine J. Sci., 1919, 14, 221—232.

A KNOWN amount of gypsum was added either to the finished cement or to clinker, the mixture was ground in a small ball mill, analysed to determine the SO_2 content and subjected to the usual physical tests. With the particular cement tested, for laboratory samples containing up to 2.5% SO_2 , the time of setting was practically independent of the SO_2 content; but when the clinker was ground in the usual way in the cement plant a quick or "flash" set was obtained if the SO_2 content was below 1.5%, an irregular or erratic set for a SO_2 content between 1.5 and 1.8%, and a normal slow setting for a SO_2 content between 1.8 and 2.1%, the higher limit being the maximum allowed by the U.S. Government specifications. The effect of exposure of the cement to air was very variable, and was independent of the SO_2 content. Experiments on the addition of lime up to 2% to cement with SO_2 content varying from 1.5 to 2.0% showed that the setting time increases with the proportion of lime, but the effect is independent of the SO_2 content.—W. F. F.

Asphalt rock; Synthetic — with special reference to Zimmer's process. Kröhnke. Chem.-Zeit., 1920, 44, 253—255.

NATURAL asphalt stone can be compressed to a hard and compact mass, whereas the artificial products obtained by mixing bitumen with finely-powdered mineral matter (limestone) fail in this respect. Natural asphalt stone heated to 120° C. crumbles to a brown powder which can be stamped to a hard mass of higher density. If it be heated to a higher temperature than 150° C. it loses this property and gives a "dead" product which is poor and sandy

in texture. Zimmer considers that the mineral matter in rock asphalt is chemically united with the bitumen through the medium of salts of sulphonated acids which have resulted in the course of the production of petroleum. The properties of Zimmer's asphalt (U.S. Pats. 1,237,852 and 1,319,918; this J., 1917, 1095; 1919, 948 A) are compared with those of Swiss, Abruzzi, and Sicilian products, and it is considered that the artificial material, on account of its higher dropping point and lower solidifying point, is superior to the natural substance. The composition and properties of a number of artificial rock asphalts are tabulated.—A. E. D.

Wood; Effect of viscosity on the penetration of creosote into —. E. Bateman. Chem. and Met. Eng., 1920, 22, 359—360.

A DEFINITE relationship exists between the absolute viscosity of creosote and its penetration into wood. For longleaf pine and noble fir with a time of treatment of 2 hrs. and a pressure of 75 lb. per sq. in., for the longitudinal penetration, $yx=k$; for tangential penetration, $y\sqrt{x^3}=k_1$; and for radial penetration, $yx^2=k_2$; x being the penetration, y the absolute viscosity, and k_1 , k_2 , and k_3 being constants. In a large number of experiments the maximum value of xy was found to be 0.6, the minimum value 0.09, and the average value 0.3. Change of temperature of the oil has no other effect than that of changing the viscosity, nor has the presence of free carbon in tar creosote any other effect than is to be expected from increased viscosity. Factors affecting the penetration are viscosity, time of treatment, pressure during the application, and variations in the wood, but the influence of changes in the last three is not definitely known.—W. J. W.

PATENTS.

Woods; Process for hardening [fireproofing] and preserving permeable soft —. A. Lambert, Rome. Eng. Pat. 139,974, 11.6.19. (Appl. 14,789/19.)

PERMEABLE soft woods are impregnated under pressure, with an ammoniacal solution of copper and zinc salts, borax, potassium chromate, and Portland cement, with or without salicylic acid and sodium fluoride.—A. B. S.

Lumber; Process for the drying and curing of —. O. E. Jacobs, Kalamazoo, Mich. U.S. Pat. 1,333,848, 16.3.20. Appl., 15.9.16.

LUMBER, enclosed in a suitable vessel, is heated to about 100° F. (38° C.) to air-dry the surface, and then treated with live steam at about 20 lb. pressure until it has become evenly heated throughout to a temperature not exceeding 250° F. (121° C.). Steam is then blown off and the chamber is subjected to the action of a vacuum, which is continued, with the lumber maintained at 100°—120° F. (38°—49° C.), until the latter is dried.

—W. E. F. P.

Heat-insulating material and process of making the same. R. B. Macdonald, Oakland, Cal., Assignor to W. H. Winkley, Los Angeles, Cal. U.S. Pat. 1,332,348, 2.3.20. Appl., 1.7.18.

A HEAT-INSULATING material is formed from a mixture of heat-insulating earth, alkali, starch, and water, a portion of the alkali being combined with the earth to form a silicate, and the material having a large number of air-cells formed by the drying of the starch.—A. B. S.

Heat-insulating material and process of making the same. W. H. Winkley, Los Angeles, Cal. U.S. Pat. 1,332,370, 2.3.20. Appl., 14.8.19.

THE material contains heat-insulating earth, sodium carbonate, hydrated lime, starch, and water.

—W. E. F. P.

Insulation; Process for utilising the final liquors of the potash industry for the production of materials for heat —. *Process for producing [heat] insulating materials from basic magnesium carbonate and fibres.* "Lipsia" Chem. Fabrik, Mügeln. Ger. Pats. (a) 304,239 and (n) 304,240, 8.7.15. Additions to 303,310.

(a) The magnesia contained in the final liquors of the potash industry is precipitated as carbonate, $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$, on suitable fibrous tissue. On drying, the carbonate is converted into basic carbonate, and a very light, porous product of low thermal conductivity is obtained. (n) Hydrated magnesium carbonate is first produced and then converted into basic carbonate and precipitated on fibrous tissue.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Nitrogen in steel; Effects produced by —. G. F. Comstock and W. E. Ruder. Chem. and Met. Eng., 1920, 22, 399—405.

AN outline is given of published researches on nitrogen in steel, together with photo-micrographs showing the structures produced. Experiments were conducted to determine the effect of heat treatment, especially the rate of cooling, on the micro-structure of nitrogenised pure iron. Five samples were cut from a $\frac{1}{4}$ in. swaged bar of pure, vacuum-fused, electrolytic iron which had been heated for 3 hours to 700° C. in a stream of ammonia gas. Four of these were heated for 15 mins. to 600°, 700°, 800°, and 950° C. respectively, and then quenched with water, after which they were again heated for 15 mins. at the same temperatures and allowed to cool with the furnace. The fifth sample was heated to 1000° C. and slowly cooled. In the first case, the

nitride needles were absorbed by the ferrite and held in solution in the quenched sample, appearing as pearlitic patches and intergranular material in the slowly cooled sample. In sample 2, quenched, the grains were larger, and the nitrogen only appeared at the boundaries. The presence of needles in the slowly cooled sample indicates that a minimum temperature of 700° C. with slow cooling is necessary for their appearance. The third sample showed similar results to sample 2, except for lighter and wider grain boundaries. At 950° C. (sample 4) all the nitride was absorbed and retained in solution on quenching, and after slow cooling the grain was smaller and the nitride appeared as needles at the boundaries. Diffusion inwards of the outside nitride band had also taken place. The fifth sample showed needles and widened grain boundaries and rapid diffusion inwards of the outside nitride band. The experiments show that nitrogen occurs in various forms, dependent on treatment, and may not be visible at all, even in highly nitrogenised steel. The dark pearlitic patches do not necessarily denote carbon, but are a function of the nitrogen present and the rate of cooling. The needles are not Neumann's lines or slip bands caused by cutting, as they neither disappear on heating above A_c , nor appear in the quenched as well as the slowly-cooled samples. These lines appear to be due to a nitride of iron, soluble at 700° C. in ferrite, retained in solution by quenching but reappearing at the boundaries on slow cooling.—W. J. W.

Iron objects; Cooling of highly heated —. F. Riedel. Stahl u. Eisen, 1920, 40, 1—9.

FORMULÆ have been devised for calculating the rate of cooling of highly heated iron objects by radiation and by conduction. Results of experiments on heat radiation were in fair agreement with the calculated results. The temperature distribution in the interior of the iron bodies during cooling is also discussed, and the results of some experiments are given.—J. W. D.

Gold and silver; Electro-deposition of — from cyanide solutions. S. B. Christy. U.S. Bureau of Mines. Bull 150. 1919. Pp. 171.

THE paper, which embodies the results of twenty years' investigations on the electro-deposition of gold and silver from dilute cyanide solutions such as are obtained in the leaching of ores, contains a review of all the methods that have been proposed, more especially those which the author himself has worked out (see U.S. Pats 613,096 of 1900; 756,328 of 1904; and 883,170 of 1908; this J., 1901, 494; 1908, 454). Clear solutions and rapid circulation are necessary for good results. A large cathode area and an excess of potassium cyanide above that required to form the double cyanides are necessary for rapid and complete precipitation, and, if the voltage is kept low and the circulation rapid, a considerable amount of cyanide is regenerated. The current should be stopped at the point at which the amperage becomes constant. The use of pervious electrodes (fragments of carbon packed in boxes) both as anodes and cathodes has been adopted. A complete description of the construction and working of a model plant is given. The cell consists of an oblong wooden box containing a simple pervious cathode at one end and a simple pervious anode at the other. The intervening space is filled up with a series of compound pervious electrodes (U.S. Pat. 883,170; this J., 1908, 454), $\frac{1}{4}$ in. apart with a potential of 3.5 volts between each. The electrodes are all made up of "Excelsior" charcoal (carbonised "Excelsior fibre") packed in wooden frames, both sides of which are covered with cheesecloth. The solution is circulated through the box by means of a small centrifugal pump; the speed of circulation is determined to a large extent by the current gap, a $\frac{1}{4}$ in. gap giving

three times the capacity that a $\frac{1}{2}$ in. gap gives. In the former case, for example, for a 96% precipitation a maximum capacity of 144 tons per 25 hours for a 1-ton box was obtained.—A. R. P.

Zinc; Reactions of the metallurgy of —. M. Lemarchands. *Comptes rend.*, 1920, 170, 805—807.

In an atmosphere of nitrogen zinc oxide is readily reduced directly by carbon without the intermediate formation of carbon monoxide. The amount of carbon entering into the reaction is intermediate between the amounts necessary if carbon monoxide or carbon dioxide is respectively the gaseous product. In explanation of this the author states that the reduction of zinc oxide by carbon monoxide takes place with a velocity superior to the reduction of carbon dioxide by carbon and commences at a lower temperature, i.e., 350° C. as against 400° C. for the latter.—W. G.

Electrolytic zinc production; Method for analytical control of —. H. F. Bradley. *Chem. and Met. Eng.*, 1920, 22, 651—65.

A DESCRIPTION is given of methods for analysing leaching and electrolyte solutions, concentrates, calcine and leach residues, zinc dust precipitate, and anode scale from cells.

Roasting; Physical chemistry of —. II. *Equilibria in the system lead-sulphur-oxygen*. W. Reinders. *Z. anorg. Chem.*, 1919, 109, 52—62.

THE results of Schenck and Albers (this J., 1919, 370 A) are criticised and shown to be untrustworthy and in some cases, particularly the quintuple points in the system lead-sulphur-oxygen, impossible.—J. F. S.

Coal dust in steel mills. Tracy. See IIA.

Catalysis. Dhar. See VII.

Films of metalloids and metals. Braly. See XXIII.

PATENTS.

Aluminium; Solder for —. F. F. Boisselier, Colombes, France. *Eng. Pat.* 124,715, 30.1.19. (Appl. 2288/19.) *Int. Conv.*, 26.3.18.

AN alloy of the composition Al 28%, Zn 36.5—37.5%, Sn 33%, Cu 1.5—2.5%.—J. W. D.

Solder. C. W. Hill, Edgewood, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U. S. Pat. 1,333,619, 16.3.20. *Appl.*, 22.7.18.

A SOLDER consisting of 6—10% cadmium and 94—90% lead, and containing a small but appreciable amount of zinc.—A. R. P.

Solder. G. P. Luckey, Wilksburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co. U. S. Pat. 1,333,666, 16.3.20. *Appl.*, 13.3.18.

A SOLDER consisting of an alloy of 90—94% lead and 10—6% cadmium.—A. R. P.

Electroplating. C. A. Bolton, Blagden Hill, Somerset. *Eng. Pat.* 133,967, 17.1.19. (Appl. 1271/19.)

COPPER is deposited electrolytically on aluminium or its alloys by immersing the article in strong nitric acid, then quickly "flashing" it electrolytically in a bath consisting of an acid solution of cupro-nickel sulphate or nitrate, and finally plating in an acid bath of copper sulphate or nitrate.—B. N.

Aluminium or its alloys; Preparing for electroplating —. H. D. Cunningham, Brighton. *Eng. Pat.* 139,967, 4.6.19. (Appl. 14,111/19.)

THE articles are scoured with an abrasive such as

pumice, or brickdust moistened with water at 80° F. (27° C.), washed, then either subjected to a second scouring with abrasive material moistened with a solution of copper sulphate at 90° F. (32° C.) to produce a thin coating of copper, or placed in an acidulated bath of copper sulphate, and subsequently a thicker coating of copper is deposited by electrolysis using a low voltage.—J. W. D.

Metal; Method of preparing — to be galvanised or coated. H. G. Harmeling, Paducah, Ky., Assignor to J. L. Fay, St. Louis, Mo. U. S. Pat. 1,334,092, 16.3.20. *Appl.* 29.7.18.

THE metal is heated and subjected to the action of hot acetic acid solution.—J. W. D.

Metals; Process for coating substances having greatly developed surface, with heavy — or insoluble salts thereof. H. Bechhold, Frankfurt. *Ger. Pat.* 309,187, 11.5.18.

THE substance to be coated is allowed to absorb a soluble salt of the heavy metal, from aqueous solution, and the salt is then converted into an insoluble compound or reduced to metal. For example, 100 grms. of bolus is digested with 1 litre of 0.4% copper sulphate solution; the absorbed salt is converted into hydroxide by means of sodium hydroxide, and then warmed. The oxide layer thus produced may be reduced by means of hydrogen or hydrazine. A deposit of silver on charcoal may be similarly obtained, by means of formaldehyde.—J. H. L.

Ore concentration. E. C. R. Marks, London. From Luckenbach Processes, Inc., San Francisco, Cal., U. S. A. *Eng. Pat.* 139,535, 4.11.18. (Appl. 18,030/18.)

THE ore is brought in contact with a mineral selective agent, e.g., a mixture of rubber solution and petroleum grease (see also *Eng. Pats.* 133,277 and 133,498; this J., 1919, 909 A), supported on a travelling belt, rotating cylinder, or rotating table, or by a matted or tangled mass of material such as wood shavings or mineral wool. The valuable mineral constituents adhere to the selective agent and may be subsequently separated by treatment with hot water, centrifuging, or the like.—J. W. D.

Furnaces; Tilting crucible or melting pot —. Soc. des Alliages et Bronzes Forgeables, Paris. *Eng. Pat.* 140,015, 26.9.19. (Appl. 23,746/19.) *Int. Conv.* 21.7.19.

THE axis of the trunnions on which the tilting takes place is tangential to the edge of the mouth of the crucible at the point or very close to the point over which the molten metal flows on pouring.—J. W. D.

Carbonizing [case-hardening] furnace. J. H. L. De Bats, Zelenople, Pa., Assignor to New Process Metals Corporation, Wilmington, Del. U. S. Pat. 1,333,796, 16.3.20. *Appl.*, 19.8.18.

A CARBONISING furnace consists of a hermetically closed rotating drum, to receive the carbonising material and the metal to be carbonised, and an interior flue, which is arranged along the axis of the drum, and is heated by means of an injector burner.—A. R. P.

Blast furnace. C. H. Mace, Denver, Colo., Assignor to A. T. Carozza, Baltimore, Md. U. S. Pat. 1,334,310, 23.3.20. *Appl.*, 28.9.17.

THE tuyères between the shaft and crucible are diametrically opposed, rectangular in section, with straight parallel sides. The continuation of the sides form connecting surfaces between opposite tuyères.—W. F. F.

Molten metal; Removing impurities from —. W. White, Washington, D.C. U.S. Pat. 1,332,585, 2.3.20. Appl., 1.11.18.

GASES and other impurities are removed from molten metal contained in a crucible, by imparting to the metal a rotary motion by means of a paddle, whereby the surface of the metal is displaced into a vertical position around the sides of the crucible, and the sound metal is forced towards the exterior of the mass. The rotary movement is then slowly reduced so as to allow the metal to fall back gradually to its normal position, and the portions of the charge containing the impurities are separated from the sound metal.—A. R. P.

Tungsten crucible and method of making and using same. J. H. Robertson and D. Jankower, New York. U.S. Pat. 1,333,036, 9.3.20. Appl., 14.7.19.

A CRUCIBLE is made from a disc of sheet tungsten which is laid over the top of a die electrode; the other electrode, in the form of a plunger, is brought down to make contact with the disc, and, when the latter is hot and in a pliable condition, presses it into the die, thereby forming the crucible. Alternating current is used and a regulating rheostat is included in the circuit.—A. R. P.

Copper-lead smelting process. W. McA. Johnson, Hartford, Conn. U.S. Pat. 1,333,720, 16.3.20. Appl., 24.10.14.

AN acid and a basic ore mixture are heated to a high temperature (1200° C.) in separate rotary kilns and then mixed and smelted by means of internally developed heat in a closed container, i.e., an electric furnace. The charge is tapped into, and allowed to settle in, two electrically heated settling hearths arranged in series, and products (lead, matte, and slag) are tapped as usual.—A. R. P.

[Zinc] refining process; Ebullient —. W. McA. Johnson, Hartford, Conn. U.S. Pat. 1,333,721, 16.3.20. Appl., 12.2.16.

IMPURE spelter from an electric furnace or retort plant is melted in a settling furnace and the top layer is tapped off into an electric distilling furnace. The vapours are passed through a layer of zinc oxide to remove from the spelter any volatile impurity having a greater affinity for oxygen than zinc. The last fraction of the metal in the distilling furnace is returned to the settling furnace at the end of the day's run and the heavy lead-iron alloy, which sinks to the bottom of the latter, is tapped once a week and returned to the plant.—A. R. P.

Alloy. F. A. Fahrenwald, Cleveland, Ohio. U.S. Pat. 1,333,965, 16.3.20. Appl., 25.6.17.

A STRONG, hard, and light alloy contains aluminium and less than 65% of beryllium (glucinum).

—A. E. D.

Magnesium alloy. W. R. Veazey, Cleveland, Ohio, Assignor to The Dow Chemical Co., Midland, Mich. U.S. Pat. 1,334,193, 16.3.20. Appl., 10.10.18.

AN alloy of magnesium with relatively small proportions of manganese and copper.—J. W. D.

Sodium; Method of making metallic —. A. W. Smith and W. R. Veazey, Cleveland, Ohio, Assignors to The Dow Chemical Co., Midland, Mich. U.S. Pat. 1,334,179, 16.3.20. Appl., 12.10.18.

METALLIC sodium is produced by electrolysis of a fused mixture of sodium carbonate and sodium chloride in such proportions that the mixture has a lower melting point than either of its constituents.

—J. W. D.

Melting furnaces and the like; Lids for —. Akt.-Ges. Brown, Boveri & Co., Baden, Switzerland. Eng. Pat. 131,887, 25.8.19. (Appl. 20,858/19.) Int. Conv., 23.8.18.

Furnaces for heat treatment of metals. D. M. Cunningham, Armadale, Scotland, and Stein and Atkinson, Ltd., London. Eng. Pat. 140,238, 23.4.19. (Appl. 10,132/19.)

PATENTS.

Electrolysers; Mono-polar electrode —. G. G. Hepburn, Manchester. Eng. Pat. 139,296, 22.2.19. (Appl. 4472/19.)

A MONO-POLAR electrode electrolyser of the filter press type comprises a number of units, consisting of anodes, cathodes, frames, and diaphragms, each unit being electrically independent of the others, having independent liquid connections, and insulated from adjacent units.—B. N.

Batteries; Primary —. *Electric battery*. O. E. Ruhoff, Assignor to French Battery and Carbon Co., Madison, Wis. U.S. Pats. (A) 1,331,213, 17.2.20, and (B) 1,331,877, 24.2.20. Appl., (A) 9.11.18, (B) 5.7.18.

(A) A MATERIAL for electric batteries is made by adding a manganese compound to a suspension prepared by stirring deloculated conductive material with water, thoroughly agitating the mixture, adding sal ammoniac (ammonium chloride), or similar salt, again agitating the mixture and filtering. The material is dried, compacted, and the product ground, mixed with more carbonaceous conductive material and sal ammoniac. (B) A battery, containing carbon, powdered depolarising material, and zinc, is provided with a porous partition, which is inserted between the depolarising material and the zinc. The partition is soaked during the process of manufacture with a 1–5% solution of potassium bichromate or other salt of chromic acid, which will act on the zinc to form a product which protects it from the depolarising material when the battery is at rest, but does not affect the efficiency of the battery when in action.—B. N.

Electrolytic cell. E. A. Le Sueur, Ottawa, Canada. U.S. Pat. 1,331,571, 24.2.20. Appl., 25.1.19.

THE anode is provided with a conducting stem protected by a conducting sheath of resistant metal, and sheets of resistant metal are clamped against opposite sides of the sheath and extend from it in a lateral and downward direction.—B. N.

Plastic material practically incombustible, strong, and possessing insulating properties. D. Motta, Assignor to E. Rugiu and A. Villain, Genoa, Italy. U.S. Pat. 1,331,519, 24.2.20. Appl., 23.7.19.

A PLASTIC and elastic insulating material is prepared from paper paste without size and equal parts by volume of calcium carbonate and magnesium silicate, the weight of the combined carbonate and silicate being substantially the same as the paper paste.—B. N.

Coumarone-resin insulating material. A. A. Wells, Caldwell, N.J., Assignor to Ellis-Foster Co. U.S. Pat. 1,332,860, 2.3.20. Appl., 9.4.17.

A MOULDED electric insulator containing coumarone resin as an essential constituent.—A. de W.

Insulating liquids for transformers and switchboards; Incombustible or difficultly combustible —. H. Grossmann, Ober-Urdorf, Switzerland. Ger. Pat. 315,402, 17.2.14. Int. Conv., 31.1.14.

A NORMAL transformer oil is mixed with a more volatile incombustible insulating liquid, such as tetrachloroethane or epichlorhydrin, and a non-conducting organic base, such as aniline or dimethylaniline, which will neutralise acid decomposition products.—H. J. H.

Insulating or inflammable liquids; Process for electrically heating —. Allgem. Elektrizitäts-Ges., Berlin. Ger. Pat. 316,012, 25.10.18.

A CONDUCTING liquid carrying current is passed through a coil immersed in the liquid to be treated. The current is led in by electrodes. The heating liquid should have a high boiling point, and by maintaining it under increased pressure with the aid of a suitable safety-valve still higher temperatures can be attained.—H. J. H.

Tungsten or platinum wire coils; Process for removing metallic cores from —. Elektrische Glühlampenfabrik "Watt" A.-G., Vienna. Ger. Pat. 315,667, 18.2.19. Int. Conv., 14.3.18.

THE core is removed by an electrolytic process which leaves the coil untouched. The coil may be made

one pole of a cell, the other pole being carbon or another metal, or the two components of the coil may themselves be joined in the bath to form an electrolytic couple, whereby the core passes into solution.—H. J. H.

XII.—FATS; OILS; WAXES.

Oils; Splitting of — by means of castor seed lipase. J. J. Sudborough, H. E. Watson, and P. S. Varma. J. Indian Inst. Sci., 1919, 2, 241–265.

NICLOUX's method of enzymic hydrolysis (this J., 1904, 327, 942) was found the most suitable for the treatment of oils on a large scale. A lipase preparation from decorticated castor seeds is more active than an equivalent quantity of enzyme from undecorticated seeds. The activity of castor seed lipase begins to diminish after three days from the date of preparation. By the use of manganous sulphate as activator (0.2 part per 100 parts of oil and 4 parts of crushed castor seed) 90 to 95% of hydrolysis is effected in 48 hours. Samples of concentrated crude fermentation glycerin prepared by enzymic hydrolysis gave analytical results equal to those of a Twitchell crude glycerin, but yielded an inferior distillate and left a larger residue.

—C. A. M.

Oil splitting with germinating and resting castor seeds. K. G. Laiwala. J. Indian Inst. Sci., 1919, 2, 266–267.

THE results obtained by hydrolysing various oils by means of crushed meal from resting and germinating castor seeds showed that, on the whole, the former seeds possess greater lipolytic activity.

—C. A. M.

Castor and soya beans; Lipolytic activity of —. A. W. Barton. J. Amer. Chem. Soc., 1920, 42, 620–632.

FROM a study of the hydrolysis of lard, olive oil, and ethyl butyrate by the lipases of castor and soya beans it is deduced that the lipase of castor beans is more intense in its action than that of soya beans. The range of acidity in which action on lard and olive oil took place was practically the same with both enzymes and independent of the substrate. The degree of activity for a given acidity was practically the same for olive oil and for lard. The activity towards ethyl butyrate was less, and the range of acidity in which action took place was

much higher and narrower. It is concluded that soya and castor beans contain the same lipase or lipases, and that both contain more than one lipolytic enzyme.—J. K.

Chrysalis oil; Characters of — L. Desvergues. Ann. Chim. Analyt., 1920, 2, 80—82.

Two samples of silkworm chrysalis oil obtained from an oil works in the Rhône valley differed widely, one being a dark-brown substance resembling vaseline, and the other a pale limpid oil. The latter had the following characters: Sp. gr. at 15° C., 0.915; solidif. pt., -10° C.; n_D^{20} = 1.4665; acid value, 8.5; saponif. value, 186.1; iodine value, 83.9; unsaponifiable matter 1.3%; mol. equiv. of fatty acids, 268.6; m.pt. of fatty acids, 26.0° C.; m.pt. of saturated fatty acids, 50.0° C.; and iodine value of unsaturated fatty acids, 95.1. The semi-solid product had: Sp. gr. at 15° C. 0.961; solidif. pt., 23.5° C.; acid value, 113.0; saponif. value, 184.8; iodine value, 86.7; unsaponif. matter, 4.8%; mol. equiv. of fatty acids, 263.2; m. pt. of fatty acids, 33.3° C.; m.pt. of saturated fatty acids, 50.0° C.; and iodine value of unsaturated fatty acids, 139.6. The unsaponifiable matter from the oil contained only a small quantity of cholesterol, whereas that from the semi-solid product contained a considerable quantity. The different results given by the two samples are to be attributed to differences in the methods of extraction.—C. A. M.

Fats and oils; Determination of the iodine values of — by Winkler's bromate method. J. V. Lakhani and J. J. Sudborough. J. Indian Inst. Sci., 1916, 1, 173—179.

WINKLER's method (this J., 1914, 872) gives trustworthy results with ordinary oils and fats, provided that the addition takes place in the absence of light. In presence of diffused daylight substitution of bromine takes place to an extent which increases with the duration of contact. Correct iodine values are obtained with acids such as crotonic and cinnamic acids with α -ethylene linkages within 30 mins. if light is excluded, but the values obtained with the esters of such acids are much too low and not concordant. The use of finely powdered bone charcoal caused a considerable increase in the rate of the absorption of bromine, the iodine value of ethyl cinnamate being raised thereby from about 18.6 to 121, and that of ethyl crotonate from 24.5 to 170.3.—C. A. M.

Phloroglucinol reagent; Method of preparing — for the Kreis [rancidity] test. H. W. Dixon. J. Ind. Eng. Chem., 1920, 12, 174.

ONE HUNDRED grms. of sodium hydroxide is dissolved in 40 c.c. of water and cooled to a temperature at which a few crystals of resorcinol dropped into the liquid do not become brown; 15 grms. of resorcinol is then stirred into the liquid, the vessel is covered to exclude air and the mixture heated on a sand-bath for 2—3 hrs. until a dark chocolate-coloured melt is obtained. After cooling the mass is dissolved in 500 c.c. of water, the solution cooled in ice, acidified with hydrochloric acid, and extracted with successive 100 c.c. portions of ether. The united ethereal extracts are treated with animal charcoal and filtered, the filtrate forming a stock solution for the Kreis test (this J., 1904, 1001; Kerr, this J., 1918, 475 A).—W. P. S.

Emulsions. T. R. Briggs. J. Phys. Chem., 1920, 24, 120—126.

INTERMITTENT shaking is much more efficient for preparing emulsions than continuous shaking. The time required for complete emulsification depends on the interval of rest between the individual shakes. Emulsions are readily made by rolling or rotating cylinders containing oil and soap solution. (Cf. J.C.S., May.)—J. F. S.

Emulsions. T. R. Briggs, F. R. Du Cassé, and L. H. Clark. J. Phys. Chem., 1920, 24, 147—160.

EMULSIONS of oil and water may be made by grinding the two together in a mortar in the presence of a finely divided solid which is easily wetted. The finely divided solid serves to increase the area of the interface between oil and water and is more effective if suspended in the oil before adding the water. In the "Continental" method of preparing emulsions gum arabic acts both as finely divided solid and as emulsifying colloid. Emulsions of water in oil may be made in a mortar by using finely divided solids easily wetted by oil. (Cf. J.C.S., May.)—J. F. S.

Proso millet oil. Dunbar and Binnewies. See XIXA.

Oils and fats; Process for recovering — from soap-free waste water. Naaml. Vennoots. A. Jurgens' Vereenigde Fabrieken, Oss, Holland. Eng. Pat. 124,220, 12.3.19. (Appl. 6142/19.) Int. Conv., 9.3.18.

THE water is treated with small quantities of an electrolyte, e.g., 0.01% to 0.02% of sodium chloride, alum, or sulphuric acid, to break down the emulsion.—A. de W.

Washing and degreasing plant; [Beater-arms for] benzine — W. Irwin, Copenhall. Eng. Pat. 140,191, 4.3.19. (Appl. 5327/19.)

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

White lead; Modification of the Thompson method for the determination of acetic acid in — L. McMaster and A. E. Goldstein. J. Ind. Eng. Chem., 1920, 12, 170—171.

THE Thompson method (this J., 1905, 487) may be shortened by distilling with phosphoric acid as described until the mixture has a small bulk and then continuing the distillation with steam until about 600 c.c. of distillate is obtained. This is treated with 0.5 c.c. of phosphoric acid and distilled under a pressure of about 150 mm.; during the distillation air is admitted through a fine capillary reaching into the liquid. When 10 c.c. of the distillate requires no more than one drop of $N/10$ sodium hydroxide for neutralisation the distillation is stopped and the total distillate titrated. In the case of white lead which has been ground with oil it is almost impossible to extract the whole of the oil, and the distillate obtained in the Thompson method contains free fatty acids; the second distillation under reduced pressure yields a distillate free from fatty acids, and consequently the results obtained for acetic acid are lower than those found by the Thompson method.—W. P. S.

Lead chromates. L. Bock. Farben-Zeit., 1920, 25, 761.

THE lead chromates show many examples of change of colour with alteration of dispersity, e.g., many products of tones varying from orange to red can be brought to the same tone by grinding, whilst pale pigments can be obtained from the normal chromate, after washing, by continued standing under water. The sulphur or canary tones of the chrome yellows obtained by simultaneous precipitation of the chromate and sulphate of lead depend on their high degree of dispersity. The pigments obtained by addition of highly dispersed lead sulphate to or even precipitation of lead sulphate on to ordinary chrome yellow are not appreciably lighter in tone than the ordinary pigment, whilst their purity and opacity are inferior, simulating that of "reduced" chrome yellows.—A. de W.

Pigments; Fineness and texture of —. H. A. Gardner. Circ. 90, Paint Manufacturers' Assoc., U.S.A., and Nat. Varnish Manufacturers' Assoc. Mar., 1920. 6 pp.

THE pigment under examination is rubbed with the finger across the grooves of an Edison disc phonograph record, and the surface is then examined with the microscope. Most pigments consist of coarse particles covered with fine ones, and when examined by the method described the coarser particles are retained in the grooves with their facets arranged parallel to the plane of the record. The microscopic observation of pigments mounted on a record is best done by viewing obliquely. The number of particles in a given weight of pigment may be estimated by preparing a suspension of 1 grm. of the pigment in a litre of water containing a very little gelatin, and counting the particles in a few drops of the suspension contained in the cell of a haemocytometer.—A. de W.

Carbon black in natural gas; Apparatus for estimating —. R. O. Neal. Chem. and Met. Eng. 1920, 22, 358—359.

AN apparatus for determining the quantity of carbon black obtainable from gases of unknown composition comprises a central portion, hood, and hopper, of sheet iron, the hopper having a sliding door to enable the carbon black to be removed from a depositing plate by means of a scraper. Below the depositing plate, at an adjustable distance, is fixed the gas pipe with lava tip burners, each capable of burning 4 cb. ft. of gas per hr., and the gas supply is connected to a meter and is controlled by a needle-valve, a U-tube for determining the pressure being inserted between the meter and the burners. The apparatus may also be used without a meter by previously calibrating it against a meter and observing different pressures on the manometer tube and recording the time. The test should last at least one hour, using 15—20 cb. ft. of gas. The carbon black should be removed at intervals of 10 mins., and at the end of the test it is removed by a brush and the total weighed.—W. J. W.

Oleo-resin from Hardwickia pinnata. K. S. Iyer and J. J. Sudborough. J. Ind. Inst. Sci., 1918, 2, 29—35.

THE oleo-resin obtained from *Hardwickia pinnata* is a dark-brown viscid liquid soluble in alcohol, ether, light petroleum, acetic acid, and turpentine. It closely resembles copaiba balsam, as the following constants show: Sp. gr. at 15° C., 1.008; acid value, 90.2; saponif. value, 112.9; acetyl value, 79.6; volatile oil, 42.7%. The volatile oil, separated by distillation with superheated steam, is colourless, and has a pungent, bitter taste. It boils mainly between 248° and 253° C., and its physical constants closely resemble those of caryophyllene, the nitroschloride of which was actually isolated from the oil and identified. The residual resin is brittle, is completely soluble in 90% alcohol, and yields a good quality spirit or oil varnish.—G. F. M.

Oleo-resin from Dipterocarpus indicus. J. C. Mansukhani and J. J. Sudborough. J. Ind. Inst. Sci., 1918, 2, 37—45.

THE oleo-resin of *Dipterocarpus indicus* (Dhuma tree) is intermediate between the oleo-resin of *Hardwickia pinnata* (preceding abstract), and that of other *Dipterocarpus* sp. which yield the so-called garjan (gurjun) balsam. The following constants are given for the oleo-resin: Acid value, 12.6; saponif. value, 16.3; acetyl value, 48.2, total volatile oil, 67.8%. The volatile oil, isolated by steam distillation, boiled mainly at 250°—254° C. The nitroschloride was obtained from the oil in somewhat greater yield (10—11%) than that obtained from the *Hardwickia* oil, and was identified as

α -caryophyllene nitroschloride. The residual resin is harder than the *Hardwickia* resin, and gives both spirit and oil varnishes of good quality. The volatile oil apparently possesses therapeutic properties similar to copaiba oil.—G. F. M.

Varnishes; Solvent media and their effect on [synthetic resin] —. H. Wolff. Farben-Zeit., 1920, 25, 668—671.

THE solubility of synthetic resins (formolites) of different makes and even of different deliveries of the same make varies very considerably, especially in mixtures containing benzene and its homologues. This is shown by actual determinations of the benzene-carrying power of different specimens when dissolved in various solvents, e.g., ethyl and methyl acetates, methyl formate, and acetone. The viscosity curves of solutions of synthetic resins in acetone-benzene mixtures show that with increasing proportion of benzene to acetone there is a change from molecular to colloidal dispersed systems. In some cases precipitation or even gel-formation results from increasing addition of benzene. The persistent softness of the films left when some formolite varnishes are allowed to dry spontaneously is attributable to the selective evaporation of the solvent in the film, the solvent of higher boiling-point and weaker solvent power being retained to a proportionately greater degree as evaporation proceeds, so that a surface layer of relatively impermeable gel of the resin in the indifferent solvent is formed, which inhibits further evaporation in the under layers. The solvents chosen for use in formolite varnishes should therefore be of such nature as to permit of a large addition of the poorer of the solvents without precipitation of the resin, or the more active solvent should possess the lowest rate of evaporation in the mixture. Alternatively a component, e.g., pyridine, may be added which diminishes the selective evaporation of the active and non-active solvents.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PRECHA.

Rubber goods; Determination of cellulose in —. S. W. Epstein and R. L. Moore. *Indiarubber J.*, 1920, 59, 559—566.

ONE half gram of the rubber is digested with 25 c.c. of freshly distilled cresol (b. pt. 195° C.) for 4 hours at 160°—185° C., then cooled and 200 c.c. of light petroleum spirit (b. pt. 45°—50° C.) added with constant agitation. After allowing to settle and decanting the liquid through a Gooch crucible containing a pad of acid-treated, ignited asbestos, the residue is washed thrice with petroleum spirit, five times with hot benzene, and once or twice with acetone; it is then treated with hot hydrochloric acid (10%), transferred completely to the crucible, washed 10 times with hydrochloric acid, then with water until free from chlorides, and treated with acetone and subsequently with a mixture of acetone and carbon bisulphide (1:1) until the extracts are colourless. The residue is washed with alcohol, dried for 90 min. at 105° C., transferred to a weighing bottle and weighed. The extracted material is digested in a beaker with 15 c.c. of acetic anhydride and 0.5 c.c. of sulphuric acid for 30 min. at 75° C., cooled, treated with 25 c.c. of 90% acetic acid, filtered slowly through a pad of treated asbestos in a Gooch crucible, washed repeatedly with hot 90% acetic acid and then 5 times with acetone. The crucible is placed in a weighing bottle, dried for 2 hours at 150° C., and then weighed. The loss in weight on acetylation represents the cellulose. The presence of leather does not interfere with the method, but in such case it is desirable to digest with cresol at 120° C. for 16 hours. The acetylation process indicates 95% of any wood present, 90% of any jute, 21% of cork, and 70% of any leather.

XV.—LEATHER; BONE; HORN; GLUE.

Molybdenum value [of tannins]; Simplified method for the determination of the —. R. Lauffmann. *Ledertechn. Rundsch.*, 1919, 11, 93—91. *Chem. Zentr.*, 1920, 91, II., 220. (See also this J., 1913, 153.)

TEN c.c. of filtered tannin solution of about four

times the usual strength for analysis is mixed with 10 c.c. of a reagent composed of equal vols. of 10% ammonium molybdate and 15% ammonium chloride solutions and filtered. Ten c.c. of the filtrate is evaporated to dryness and dried in the water oven to constant weight. At the same time, 10 c.c. of the tannin solution and 10 c.c. of the above reagent are evaporated together in a basin and dried to constant weight. The weight found by the evaporation of the filtrate is doubled and the product is subtracted from the dry weight of the unfiltered mixture, the difference giving the weight of the precipitate. This is calculated as a percentage of the total dissolved solids of the tannin extract. The following molybdenum values are given: Oak bark extract 65.5—81.3; oak wood extract 112.0—152.1; spruce bark extract 23.6—36.7; chestnut extract 148.2—191.3; quebracho extract, solid, not sulphited 2.0—33.8; the same, fluid, sulphited 0.0—23.4; mangrove extract 117.9; mimosa bark extract 67.9.—J. F. B.

XVI.—SOILS; FERTILISERS.

Lime; Absorption of — by soils. F. J. Warth and M. P. Saw. *Mem. Dep. Agric. India*, 1919, 5, 157—172.

EXPERIMENTS on the absorption by different types of soil of calcium carbonate from solutions of calcium bicarbonate of different concentrations in the presence of varying amounts of carbon dioxide showed that carbon dioxide plays an important part in the equilibrium attained. A new method of determining the lime requirement of a soil may be based on the experimental results, but is too difficult and involved for ordinary laboratory work. —W. G.

Soil; Retention of certain acidic to basic constituents of the — affected by ammonium sulphate and sodium nitrate. L. P. Howard. *Soil Sci.*, 1919, 8, 313—321.

THE "acidity" in a soil caused by long continued use of ammonium sulphate is a result of a change

in the ratio of acids to bases. Iron and aluminium take the places normally occupied by the stronger bases, calcium and magnesium, and the salts of the weaker bases undergo hydrolysis and give rise to a definite hydrogen ion concentration in the soil solution. (*Cf.* J. C. S., i., 416).—W. G.

Potassium-bearing minerals as a source of potassium for plant growth. E. de Turk. Soil Sci., 1919, 8, 269—301.

TRIALS were made with orthoclase, microcline, leucite, alunite, and lepidolite on a very loose peaty soil quite free from sand and from roots or other residues of recently grown plants. In the pot experiments, where crops were grown, the minerals were added at a rate equivalent to 2 tons per acre, and one ton of ground limestone per acre was also added. Lepidolite was detrimental to the growth of buckwheat under these conditions, whilst the other finely-ground minerals gave an increase in yield of 21—35%. The additional application of organic manures or soluble sodium or magnesium salts did not increase the yield of crop or the availability of the potash in the minerals used. Except in the case of lepidolite, the solubility of the minerals used was low. This high solubility of lepidolite probably accounts for its effect in stunting the crop, some toxic element, such as lithium, possibly being dissolved from the mineral. The solubility of all the minerals was increased by the presence of ammonium chloride or of decomposing alfalfa (lucerne). The low availability of the potash in dune sand is due to the fact that most of it is contained in the larger particles, which offer a relatively small surface to the solvent action of the water. The increase in solubility produced by grinding such sands is not sufficient to be of practical value.—W. G.

Iron-aluminium phosphates; Utilisation of —. G. H. Stanley. J. S. Afr. Assoc. Anal. Chem., 1920, 3, 13—21.

SAMPLES of iron-aluminium phosphate from a large deposit at Saldanha Bay, S. Africa, had the following composition:— P_2O_5 , 5.68—32.68; Fe_2O_3 , 2.60—11.96; Al_2O_3 , 2.22—17.29; and SiO_2 and insoluble matter, 15.67—77.05%. The material is therefore of less value than Redonda phosphate. By heating the Saldanha phosphate rock with limestone and small coal in an iron vessel with perforated false bottom, whilst blowing air through the heated mass, it could be converted into a material resembling a low-grade basic slag which could be produced and sold at about 7s. per unit of P_2O_5 . By this process about 75% of the phosphoric anhydride is converted into a citric-soluble form.

—C. A. M.

Plants: Influence of organic compounds on the development of —. IV. G. Ciamician and C. Ravenna. Atti R. Accad. Lincei, 1920, 29, i., 7—13. (Compare this J., 1919, 297 A.)

FURTHER experiments have been carried out with compounds belonging to a number of different chemical classes. (*Cf.* J. C. S., i., 408).—T. H. P.

Nitrogen [in fertilisers]; Use of potassium permanganate in determining — by the Kjeldahl method. W. Frear, W. Thomas, and H. D. Edmiston. J. Assoc. Off. Agric. Chem., 1919, 3, 220—224.

THE addition of potassium permanganate at the end of the acid digestion period caused a considerable loss of nitrogen in the case of a wide range of fertilisers. The loss depended somewhat on the amount of permanganate added, but chiefly on the time of addition. If the addition was delayed for 2 mins. after the flame had been removed there was no loss.—W. P. S.

PATENTS.

Potassium compounds; Process for extracting — from rocks containing potassium and simultaneously producing nitrogen-containing fertilisers. C. Rossi, Legnana, Italy. Eng. Pat. 130,963, 12.5.19. (Appl. 11,913/19.) Int. Conv., 9.8.18.

FINELY-GROUND potash-bearing rocks such as leucite, volcanic ash, felspar, orthoclase, granite, etc., are mixed with calcium carbide and heated in a stream of nitrogen. Calcium cyanamide is formed together with a complex nitrogenous fertiliser produced by the interaction of the free carbon and the lime present and their combination with the nitrogen, whilst the potassium compounds are volatilised and may be completely recovered. The addition of coal to the rocks increases their absorption of nitrogen. A complex fertiliser, consisting of a mixture of potassium compounds with the nitrogenous product, may be obtained by keeping the temperature of reaction below the volatilising temperature of the potassium compounds.—W. J. W.

Fertilisers containing nitrogen and phosphoric acid. Norsk Hydro-Elektrisk Kvaelfabrikations-selskab, Christiania. Eng. Pat. 132,496, 25.7.19. (Appl. 18,536/19.) Int. Conv., 13.9.18.

A MIXTURE of an insoluble phosphate and a urea salt, e.g., urea nitrate, is either employed direct as a fertiliser, in which case the moisture in the soil causes reaction between the two compounds with formation of soluble phosphates, or the reaction is first effected by moistening the mixture, and the product is dried for subsequent use as a fertiliser. (Reference is directed to Eng. Pat. 17,507 of 1902; this J., 1902, 1462).—L. A. C.

XVII.—SUGARS; STARCHES; GUMS.

Dextrose; Detection and characterisation of — in plants by a new biochemical method. E. Bourquelot and M. Bridel. Comptes rend., 1920, 170, 631—635.

THE dry plant material is extracted with boiling 80% alcohol, the solution is evaporated to dryness, resinous materials are removed by extraction with ethyl acetate, and the residue is dissolved in a little water and the solution evaporated to dryness under reduced pressure. The residue is dissolved in 70% methyl alcohol, and the reducing power and rotation of the solution are measured. Emulsin is added and the solution is left to stand until no further change in its rotation occurs. The reducing power and rotation are again measured, and from their changes the amount of dextrose present may be calculated; emulsin converts 82.6% of the dextrose present in 70% methyl alcohol into β -methylglucoside even in the presence of other sugars.—W. G.

Dextrose; Determination of — in the presence of lactose. E. Hildt. Ann. Chim. Analyt., 1920, 2, 78—80.

LACTOSE may be quantitatively hydrolysed by means of Twitchell's sulpho-aromatic compounds (see this J., 1919, 51 A). A suitable catalyst is prepared by dissolving 180 grms. of sodium benzenesulphonate, free from iron, in water containing 49 grms. of pure sulphuric acid, and diluting the solution to a litre. A quantity of a solution (e.g., defecated urine), containing not more than 1 gm. of sugar, is mixed with 20 c.c. of the Twitchell reagent, made up to 100 c.c., shaken, and filtered, and 50 c.c. of the filtrate hydrolysed for 6 hours at 95°—98° C. The remainder of the solution is used for the titration of reducing sugars by means of Fehling's solution diluted with 4 vols. of water, and treated with 5 or 6 drops of sodium hydroxide solution. The

hydrolysed portion, after cooling and dilution to 50 c.c., is titrated in the same way. If n and n' be the number of c.c. required to decolorise 10 c.c. of Fehling's solution before and after hydrolysis respectively, the amounts of hydrated lactose (x) and anhydrous dextrose (y) in grms. per 100 c.c. are given by the equations: $x = 3.55/n' - 3.55/n$, and $y = 1.458/n' + 3.34/n$.—C. A. M.

XVIII.—FERMENTATION INDUSTRIES.

Malting and brewing. P. Petit. Brasserie et Malterie, 1919, 9, 241—245, 257—261.

By restricting germination the malting loss is reduced, but the short-grown malt obtained is imperfectly modified in respect of proteins, which remain to a large extent insoluble. They can be partially dissolved by pre-mashing, but are liable to precipitation by a slight change of reaction of the wort. The conversion of these imperfectly dissolved proteins into completely soluble degradation products by "protein rest" is incomplete, because the short-grown malt is deficient in proteolytic power. Hence the increased yield of extract attained by means of pre-mashing and the "protein rest" consists largely of proteins in a state of unstable solution. Their contribution to flavour and head-formation is of doubtful value, and they are certainly liable to cause difficulties in clarification and protein haze in the finished beer.—J. H. L.

Alcoholic fermentation; Chemistry of —. C. Neuberg and E. Reinfurth. Ber., 1920, 53, 462—469.

In reply to Zerner (this J., 1920, 276 A) it is pointed out that the impossibility of effecting a quantitative conversion of sugar into glycerol and acetaldehyde by fermentation in the presence of sodium sulphite is to be attributed to the gradually increasing alkalinity of the solution and not to the slowness of reaction between aldehyde and sulphite and, further, that Zerner's conclusion that the formation of pyruvic acid cannot be the preliminary step in the production of acetaldehyde is based on faulty experiment. (Cf. J. C. S., i., 406).—H. W.

Pyruvic acid; Biochemical production of —. A. Fernbach and M. Schoen. Comptes rend., 1920, 170, 764—766.

FURTHER evidence is given that in a mineral nutrient solution pyruvic acid is formed during alcoholic fermentation by yeast, providing the medium is kept neutral by the presence of an excess of calcium carbonate.—W. G.

Wine; Bacterial decomposition of tartaric acid and glycerol in —. H. Müller-Thurgau and A. Osterwalder. Landw. Jahrb. der Schweiz, 1919. Chem. Zentr., 1920, 91, II., 90—91.

A NUMBER of Swiss red wines developed, some weeks or months after the decomposition of the malic acid was complete, maladies due to bacterial decomposition of tartaric acid and glycerol in some cases, and of glycerol alone in others. These maladies were associated with evolution of carbon dioxide and increase of volatile acidity (acetic with a small proportion of propionic acid); very frequently the wines lost their red colour to some extent and became brownish, and in a few cases they acquired a bitter flavour. Access of air aggravated the trouble. In some cases the tartaric acid was eventually decomposed completely, but about 0.2—0.3 % of glycerol remained in all cases. From a wine in which both tartaric acid and glycerol underwent decomposition, two new organisms were isolated, viz., *Bact. tartarophthorum* and *B. tartarophthorum* var. α . Both decompose tartaric acid energetically, but whilst the former also decomposes glycerol the latter does so to only a slight extent. Acetic acid and carbon dioxide are produced from tartaric acid, and acetic, propionic, and lactic acids from glycerol. Both bacteria are facultative anaerobes and form non-motile and non-sporulating rods 0.8—1 μ thick. They decompose malic acid readily and produce mannitol from levulose. High acidity and high tannin-content have an inhibitive influence on the maladies described, whilst high temperatures promote them. Suitable preventive measures are storage at low temperatures, use of sulphur dioxide and metabisulphite, and pasteurisation; but in the case of wines similar to those investigated these measures should not be applied until after the decomposition of the malic acid is complete.—J. H. L.

Methyl alcohol in spirits; Detection of —. P. Hasse. Pharm. Zentr., 1920, 61, 177—182.

THE sample is distilled and 0.5 c.c. of the distillate (containing not more than 0.025 c.c. of alcohol) is mixed with 1 c.c. of 5 % potassium permanganate solution, 2.5 c.c. of dilute sulphuric acid (sulphuric acid 19 grms., water 200 c.c.) and, after standing 2 mins., the mixture is decolorised by the addition of 1 c.c. of 10 % oxalic acid solution. To 0.5 c.c. of this mixture are then added 1 drop of peptone solution (=2.5 mgrms. of peptone) and 1 c.c. of sulphuric acid containing iron (0.05 gm. of iron alum dissolved in 1 c.c. of water and added to 300 grms. of sulphuric acid). A deep blue colour is obtained if the spirit contains 1 μ of methyl alcohol; a red-blue colour is produced by 0.3 % of the alcohol. Pure ethyl alcohol gives a yellowish-red coloration with the test. If an indication of the presence of methyl alcohol is obtained, it should be confirmed by the morphine and magenta-sulphurous acid tests.—W. P. S.

Oralic acid. Bau. See XX.

PATENTS.

(A—C) *Yeast; Manufacture of pressed* —. (D—I) *Manufacture of yeast with little or no production of alcohol.* Verein der Spiritus-Fabrikanten in Deutschland, Berlin. Ger. Pats. (A) 300,663, 25.2.15; (B) 303,251, 16.3.15; (C) 303,252, 20.8.15; (D) 300,662, 17.3.15; (E) 303,221, 1.4.15; (F) 303,222, 20.3.15; (G) 303,253, 8.5.15; (H) 304,241, 13.4.15; and (I) 301,242, 16.4.15.

(A) YEAST is grown, by the ordinary aeration process, in solutions containing not more than 2 % of refined sugar or raw beet sugar, together with not less than 15 parts of mineral nutrient salts per 100 parts of sugar. The yeast produced has a normal character and colour. (B) The mineral acid liberated

during the fermentation is neutralised by addition of suitable alkaline mineral salts, *e.g.*, carbonates. When molasses is used the basic substances therein neutralise a part of the free acid. The process may be applied also to fermentations carried out in presence of mineral salts for other purposes than the production of yeast. (c) Sodium salts may be substituted for potassium salts in the nutrient liquid. The "soda yeast" obtained possesses a working power equal to that of a good bakers' yeast. (d) Yeast is pitched in highly diluted wort, and stronger wort is added slowly and continuously during the growth of the yeast, whereby, owing to the continuous consumption of nutrient substances, the concentration of the wort remains throughout such as to ensure the best and most rapid assimilation of the nutriment supplied. (e) Wort containing yeast is continuously drawn off from the lower part of the vat as fast as fresh nutrient solution is added. The yeast is separated by centrifugal means from the wort thus drawn off. (f) Sugar and mineral salts are employed for the preparation of the wort. The mineral salts may amount to half the weight of the sugar used. In using ammonium sulphate as source of nitrogen the acidity (free sulphuric acid) increases very rapidly, and is neutralised by means of alkalis or alkaline salts. (g) Antiseptics assimilable by yeast, *e.g.*, formaldehyde and formic acid, are added to the nutrient solution. The proportions required in the solution, which is added continuously to the vat (0.01–0.1% of formaldehyde and 0.03–0.3% of formic acid), are too small to injure the yeast. (h) In the process claimed in (e) so much yeast is pitched at the commencement as can be grown in the quantity of liquid then present. (i) In the process claimed in (f) a solution of free alkalis or alkaline carbonates is added continuously to the wort, to furnish mineral nutriment to the yeast, and a faintly alkaline reaction is maintained in the wort during yeast growth.—J. H. L.

Cellulose; Process for saccharifying plant material containing —. C. G. Schwalbe, Eberswalde. Ger. Pat. 305,690, 4.5.16.

THE moist material, containing less than 50% of water, is subjected to the action of a gaseous acid such as hydrochloric, hydrofluoric, or sulphurous acid, until it is swollen but not dissolved, the heat produced being eliminated by cooling, if necessary below the ordinary temperature. The gaseous acid is then removed and the gelatinous material is saccharified by dilute acid under atmospheric or higher pressure. From 100 parts of wood dry substance it is possible to obtain 70 parts of soluble matter containing nearly the theoretical yield of dextrose and pentoses.—J. H. L.

Caramel. Eng. Pat. 137,339. See XVII.

Alcohol in beverages. U.S. Pat. 1,333,905. See XXIII.

XIXA.—FOODS.

Milk; Action of colloids in the reductase test for —. E. Eichwald. Z. Unters. Nahr. Genussm., 1919, 38, 359–361.

THE colloids (proteins and fat) present in milk appear to have an influence on the Methylene Blue test for reductase in milk; the finer the state of division of the colloids the slower is the rate at which the colour is destroyed.—W. P. S.

Milk; Analysis of —. [Influence of formaldehyde, etc.] C. Porcher. Ann. Falsif. 1920, 13, 35–37.

THE addition of 1 drop of 40% formaldehyde solution to 50 c.c. of milk did not affect the determina-

tion of the lactose, but when 5 drops were added the amount of lactose found increased from 5.00 to 5.31%.—W. P. S.

Proso millet; analysis of its oil. A characteristic alcohol. B. A. Dunbar and E. R. Binnewies. J. Amer. Chem. Soc., 1920, 42, 658–666.

MEAL from the hulled grain of the proso millet (*Panicum miliacum*) contained 2.86% ash, 12.80% moisture, 6.25% crude fibre, 15.86% crude protein, 5.07% oil (ether extract), 57.16% nitrogen-free extractives, and 59.65% starch. The oil, which was extracted by petroleum spirit equally as well as by ether, when kept out of contact with the air gradually deposited thin, pearly-white plates of "prosol," $C_{44}H_{86}O_2$, m. pt. 279° C., soluble in most organic solvents, but sparingly in cold ether or alcohol. The oil separated from prosol had sp. gr. 0.9228 at 25° C.; $n_D^{20}=1.4745$; an acetyl value corresponding to 10.9% alcohols and hydroxy acids; Hübl iodine value, 92.3; Reichert-Meißl value, 2.5; glycerin content, 3.31%; free fatty acids equivalent to 11.9% oleic acid; phytosterol, 0.63%; and unsaponifiable matter, 2.52%. It showed 3.18% increase in weight after oxygenation by Livache's process, and is therefore a semi-drying oil, ranking with rapeseed oil. The soluble acids corresponded to 0.36% formic acid, a trace of acetic acid being present. Insoluble fatty acids amounted to 89.8% of the oil, 76.5% being unsaturated and consisting of about 72% palmitic acid and a residue of carnaubic and daturic acids. The saturated fatty acids contained 51.6% oleic acid, 20.4% linolic acid, and 23.7% isolinolic acid.—J. K.

Humin formed by the acid hydrolysis of proteins; Origin of the —. IV. Hydrolysis in the presence of aldehydes. III. Comparative hydrolysis of fibrin and gelatin in the presence of various aldehydes. G. E. Holm and R. A. Gortner. J. Amer. Chem. Soc., 1920, 42, 632–640.

THE results of experiments on the hydrolysis of fibrin and gelatin in presence of benzaldehyde, butyraldehyde, isobutyraldehyde, acetaldehyde, and formaldehyde respectively confirm the previous conclusion (this J., 1918, 18 A) that in a normal protein hydrolysis the formation of black acid-insoluble humin is dependent upon the presence of tryptophane in the protein molecule.—J. K.

Arginine nitrogen. Holm. See XXIII.

PATENTS.

Cheese; Process of making Emmenthal or Swiss —. C. F. Doane, Eureka, Cal. U.S. Pat. 1,334,693, 23.3.20. Appl., 23.5.19.

MILK is heated to 134°–155° F. (57°–68° C.), then cooled, and rennet added to form a curd. The curd is heated to give the necessary firmness and to expel moisture or whey.—W. F. F.

Fodder from wood; Process and apparatus for producing —. H. Mühlenbein, Cöthen. Ger. Pat. 305,090, 18.11.16.

THE wood passes continuously through a series of vessels in which it is comminuted, then subjected to known chemical treatment with alkali and with oxidising agents such as chlorine, and then separated from the liquid, mixed with other feeding-stuffs, dried and, if necessary, ground. The digesting apparatus consists of two or more vessels, capable of being heated, and fitted with stirring mechanism, perforated feed, inlet and screened outlet for the chemical agents, and a steam outlet hood. The process can be applied also to the preparation of cellulose for paper-making, and the digesting apparatus may be used in place of a diffusion battery in producing sugar juice and fodder slices from beets, and in similar cases.—J. H. L.

Fodders; Process for the better utilisation of the nutritive value of inferior —. Kriegsausschuss für Ersatzfutter G.m.b.H., Berlin. Ger. Pat. 306,464, 18.1.16.

STRAW, hay, grasses, twigs, wood waste, etc., in a comminuted or ground state are subjected to the action of a solution of calcium saccharate at the ordinary temperature, or below or above 100° C., under atmospheric or higher pressures, and dried. —J. H. L.

Sugar beets; Process for producing a fodder and foodstuff from —, especially for use as adjunct in bread-making and the like. F. von Langen, Elsdorf. Ger. Pat. 310,028, 22.7.16.

BEETS are sliced or pulped and extracted by known methods. The residue is dried to a moisture-content of less than 10%, and the juice, without any purification, is evaporated under reduced pressure to a massecuite of 80–95% dry substance. The dried beet residue, in a finely granular or mealy form, is mixed with the hot massecuite so as to obtain a loose dry product containing at least the same proportion of sugar to other dry substance as occurs in beets. —J. H. L.

Cooling foods, beverages, and the like; Means for —. A. L. Price, Chatswood, N.S.W. Eng. Pat. 139,895. (Appls. 6550, 17.3.19, and 20,473, 20.8.19.)

XIXB.—WATER PURIFICATION; SANITATION.

Sewage; Purification of — by activated sludges. R. Cambier. Comptes rend., 1920, 170, 681–681.

THERE is very rapid disappearance of ammoniacal nitrogen during the first hour from sewage in contact with activated sludge at the ordinary temperature without a corresponding increase of nitric nitrogen, which only shows a marked increase after the first hour. Temperature has a marked effect on the purification. At 0° C. purification is complete, but nitrification is retarded; maximum activity is reached at 20°–25° C. At 37° C. there is no formation of nitric nitrogen, and the sewage is not modified in appearance. Nitrous nitrogen is only found in appreciable quantities at temperatures above 30° C. Both the ammonia and colloidal matter of the sewage are for the most part absorbed by the sludge at the moment of contact. —W. G.

Activated [sewage] sludge; Formation of —. F. Diénert. Comptes rend., 1920, 170, 762–763.

IN the preparation of activated sludge air is bubbled for a certain time through sewage, which is then allowed to settle, the water drawn off, fresh sewage added, and the air again bubbled through, this being repeated daily until, during a period of bubbling of air for five consecutive hours 20 mgrms. of ammoniacal nitrogen per litre of sewage is converted into nitrous or nitric nitrogen. This period of activation varies with the sewage or water used, the volume of air, and the temperature of the water. The change from inactivity of the organisms to activity is manifested quite suddenly. —W. G.

Air; Electrical purification of —. D'Arsonval, Bordas, and Touplain. Comptes rend., 1920, 170, 636–638.

By means of a high-tension electric discharge perpendicular to the direction of the current of air, the air may be purified from solid or liquid particles or bacteria. Using a copper tube at zero potential and an axial wire at a negative potential of 25,000 to 30,000 volts, the air passing at the rate of 127 cb. m. per hr., the issuing air was absolutely sterile, and 95–97% of the solid particles was

removed. Sterilisation is probably effected by ozone produced by the high-tension discharge.

—W. G.

Hypochlorous acid; Strength of — in solution, with particular reference to *eusol*. J. McCrae. Pharm. J., 1920, 191, 273.

IN Hart's method of determining the strength of *eusol* (this J., 1920, 79A) an error is made in assuming that 2 atoms of available chlorine correspond to 1 mol. of calcium hypochlorite; actually half of the available chlorine is derived from the chloride residue. Hence the amounts of bleaching powder given by Hart must be doubled if a solution containing 0.45% of hypochlorous acid is to be obtained. —C. A. M.

Picric acid; Toxicity of —. F. Koelsch. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 63–65.

PICRIC acid, under the conditions obtaining in munition works, is a relatively harmless substance, and, with the exception of certain supersensitive persons, the workers are but little affected by it; acute or chronic poisoning was never observed by the author. In the case of workers who exhibit sensitiveness towards picric acid, the symptoms noticed are irritation of the eyes, nose, throat, and mucous membrane, cardialgia, etc., but these effects may be lessened by paying attention to personal cleanliness. In a few instances it may be necessary to remove a person from the picric acid plant to other work, but special hygienic regulations do not seem to be required. —W. P. S.

PATENTS.

Sterilising liquids; Apparatus for —. H. B. Rudd, Akron, Ohio, assignor to The Electropure Dairy Co., Chicago, Ill. U.S. Pat. 1,333,633, 16.3.20. Appl., 22.9.19.

AN upright receptacle is provided on opposite sides with electrodes which extend at an angle from the top to the bottom and form water-jacket chambers between themselves and the wall of the receptacle. The intake and discharge pipes of the apparatus communicate with each of the water-jacket chambers, and the discharge of liquid from the receptacle is controlled by thermodynamic valves operable at predetermined temperatures. —W. E. F. P.

Sewage and other effluents; [Mixing] apparatus for use in treatment of — [by the activated sludge process]. L. Whyte, Wilmslow, and H. Fothergill, Cheadle Hulme. Eng. Pat. 104,189, 28.2.19. (Appl. 5028/19.)

Water; Softening —. E. Edser and S. Tucker, London, Assignors to Minerals Separation North American Corporation, New York. U.S. Pat. 1,333,393, 9.3.20. Appl., 3.7.18.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Strychnine; Test for —. H. E. Buc. J. Assoc. Off. Agric. Chem., 1919, 3, 193.

TO 0.5 c.c. of the strychnine salt solution are added 1 grm. of amalgamated zinc and 0.5 c.c. of hydrochloric acid. After 15 mins. the liquid is decanted and treated with 0.02% potassium ferrieyanide solution, added drop by drop. A pink to rose-red coloration develops. Large amounts of some alkaloids and other organic substances interfere, but in their absence the test will detect 0.001 mgrm. of strychnine. —W. P. S.

Opium assay. D. B. Dott. Pharm. J., 1920, 194, 302.

A MODIFICATION of the British official process is

described which includes certain features taken from pharmacopœias and an improvement on the Japanese method of purifying the morphine-lime solution.—W. P. S.

Glucosides. V. *Synthesis of β-gaultherin, of methyl β-tetra-acetylglucosidoanthranilate, and of β-glucosidoresorcylic acid methyl ether.* P. Karrer and H. Weidmann. *Helv. Chim. Acta*, 1920, 3, 252—257.

By methylation of β-glucosidosalicylic acid with diazomethane, its methyl ester is obtained. Whilst structurally identical with natural gaultherin, it differs from the latter in that it is hydrolysed by emulsin, but not by gaultherase. Gaultherin is therefore the α-stereoisomeride. Mauthner's product (this J., 1913, 748 A) is identical with the tetra-acetyl derivative of the above ester, and is therefore not tetra-acetylgaultherin. (*Cf.* J.C.S., i., 395.)—J. K.

Glucosides. VI. *Configuration of glucosides.* P. Karrer. *Helv. Chim. Acta*, 1920, 3, 258—260.

PICTET has shown that levoglucosan is produced by the distillation of certain β-glucosides, but not from α-glucose (this J., 1918, 49 A; 1920, 40 A). A considerable amount is, however, obtainable from β-glucose, and the reaction is therefore conditional upon the presence of the β-configuration. Starch and cellulose, which answer to the reaction, probably contain β-glucosidic linkages, and it is possible that they contain the levoglucosan grouping. The structure of the trimethylglucose obtained by Denham and Woodhouse from cellulose (this J., 1917, 607) suggests that the glucose residues in cellulose are coupled at the points indicated:—

(*Cf.* J.C.S., i., 370.)—J. K.

Capsaicin, the pungent principle of capsicum; Constitution of —. II. E. K. Nelson. *J. Amer. Chem. Soc.*, 1920, 42, 597—599.

THE conception of capsaicin as vanillyldeceonoyl-amide (this J., 1919, 654 A; *cf.* Lapworth and Royle, this J., 1919, 843 A) is confirmed by the regeneration of capsaicin from vanillylamine and deconoyl chloride, the latter being obtained from the acid produced from capsaicin. (*Cf.* J.C.S., i., 380.)—J. K.

Peru balsam; Physical and chemical constants of —. E. C. Merrill. *J. Assoc. Off. Agric. Chem.*, 1919, 3, 194—197.

THE Hanus method is unreliable for determining the iodine value of the cinnamein separated from Peru balsam; the time of contact (30 mins.) usually employed is too short, at least 3 hrs. being required. There is no marked difference in viscosity between true and artificial Peru balsam. Cinnamein from artificial balsam has a slight optical rotation (+0.35° for 2 c.c. of cinnamein dissolved in 10 c.c. of benzene, and observed in a 100 mm. tube), and n_D^{25} less than 1.57, whilst cinnamein from genuine balsam is optically inactive, and n_D^{25} above 1.57.—W. P. S.

Truxillic acids. A. W. K. de Jong. *Proc. K. Akad. Wetensch.*, 1920, 22, 509—511.

THE isomeric truxillic acids may best be separated from cinnamic acid by sublimation at 130° C. in a current of air, and from one another first by the varying solubility of their calcium salts, and then through their barium salts. If the mixed truxillic acids are dissolved in just sufficient N/10-potassium hydroxide, and to the solution 1.5 grms. of anhydrous calcium chloride is added for each 10 c.c., the β-, δ-, and ε-acids are precipitated as

calcium salts. These are collected and converted into the barium salts, which may then be separated by their differing solubility in water. To the filtrate from the mixed calcium salts 8.5 grms. of calcium chloride is added for each 10 c.c., the calcium salt of β-cocaic acid being thereby precipitated. This is filtered off, and from the filtrate, by addition of hydrochloric acid and extraction with ether, α- and γ-truxillic acids are obtained. These may readily be separated, since the γ-acid is soluble in hot water, but the α-acid is not. (*Cf.* J.C.S., i., 389.)—W. G.

Pyrrole, indole, and carbazole; Metallic salts of —. E. C. Franklin. *J. Phys. Chem.*, 1920, 24, 81—99.

SODIUM, potassium, magnesium, and calcium salts of pyrrole, indole, and carbazole are formed by the action of the metals, and sodium, potassium, and silver salts by the action of the metal amide on the bases in liquid ammonia solution at low temperatures. The salts are all unstable, and hydrolysed vigorously by water. (*Cf.* J.C.S., i., 396.)—J. F. S.

Silver-salvarsan. A. Binz, H. Bauer, and A. Hallstein. *Ber.*, 1920, 53, 416—428.

ULTRA-FILTRATION experiments, absence of the Tyndall phenomenon, and the appearance under the ultra-microscope show that silver-salvarsan does not contain colloidal silver or silver oxide. In the formation of silver-salvarsan and its derivatives, two molecules of silver nitrate react with one molecule of the salvarsan compound, as is shown by the isolation of dichlorosalvarsan di-silver chloride $[\text{AgCl.NH}_2\text{.C}_6\text{H}_4\text{(OH).Cl.As}]_2$ in the solid state. Silver-salvarsan contains silver oxide in complex combination, but the exact mode of attachment of the metallic atoms to the salvarsan molecule remains undecided. (*Cf.* J.C.S., i., 401.)—H. W.

Oxalyl chloride and bromide; Use of — for producing acid chlorides, acid bromides, or acid anhydrides. III. R. Adams and L. H. Ulich. *J. Amer. Chem. Soc.*, 1920, 42, 599—611.

WHEN the method of preparing acid anhydrides from 1 mol. of oxalyl chloride and 2 mols. of acid (this J., 1918, 221 A) is applied to *m*- or *p*-nitro, 3,5-dinitro-, or 2,4,6-trinitrobenzoic acids, mixed anhydrides are produced, which are very stable towards excess of oxalyl chloride, but decompose on melting. Aliphatic acids give less favourable results than aromatic acids, some acid being unchanged and some acid chloride being formed in addition to the anhydride. Acid chlorides may be prepared smoothly and in good yield by boiling the anhydrides, including those of the above nitro-compounds, with 1.5—2.5 mols. of oxalyl chloride alone or in presence of benzene for two hours; except in the case of the nitrobenzoic acids, the anhydrides may be replaced by the acids themselves. A method of preparing anhydrides and chlorides which gives still better results and has not the above limitations, consists in the treatment of the sodium salts with 1 or 1.5 mols. respectively of oxalyl chloride. Oxalyl bromide behaves in a similar manner to the chloride, and gives better yields of acid bromides than phosphorus pentabromide. (*Cf.* J.C.S., i., 386.)—J. K.

Ethylene and sulphur chloride; Mechanism of the reaction between —. J. B. Conant, E. B. Hartshorn, and G. O. Richardson. *J. Amer. Chem. Soc.*, 1920, 42, 585—595.

THE formation of ββ'-dichlorodiethyl sulphide by the action of sulphur monochloride on ethylene at 40°—60° C. can be best represented by the equations: (1) $\text{S}_2\text{Cl}_2 \rightleftharpoons \text{S} + \text{SCl}_2$; (2) $\text{C}_2\text{H}_4 + \text{SCl}_2 \rightarrow \text{CH}_2\text{Cl.SCl}$; (3) $\text{C}_2\text{H}_4 + \text{CH}_2\text{ClCH}_2\text{SCl} \rightarrow (\text{CH}_2\text{ClCH}_2)_2\text{S}$. Reaction (3) becomes appreciable only when the

absorption of ethylene reaches about 30% of the total, but towards the end it predominates. An almost pure compound of formula $\text{CH}_2\text{Cl.CH}_2\text{Cl.SCl}$ can be obtained by shaking sulphur dichloride with excess of ethylene at 0°C . The product prepared in a similar manner from sulphur monochloride has similar properties, but contains small amounts of unchanged monochloride and dichlorodiethyl sulphide. When the crude dichlorodiethyl sulphide is distilled under reduced pressure, there is a residue, which, when freed from a small amount of elementary sulphur, corresponds approximately in composition to the formula $(\text{CH}_2\text{Cl.CH}_2)_2\text{S}_2$. Correspondingly, only about 50% of the theoretical amount of sulphur is produced in the reaction (it is not precipitated, but is in colloidal solution, from which it separates slowly at the ordinary temperature and rapidly at 100°C ., leaving the freezing point of the disulphide unchanged); in addition, the amount of ethylene absorbed is only 95% of that theoretically required for its complete conversion into the sulphide and only about 80% of the theoretical quantity of sulphide is actually produced. (*Cf.* J.C.S., i., 363.)—J. K.

Nitriles; New method of formation of — by catalysis. A. Mailhe. *Comptes rend.*, 1920, 170, 813–815.

Is the method previously described for the catalytic preparation of aliphatic or aromatic nitriles (this J., 1918, 74 A) by passing the vapours of the corresponding esters along with ammonia over alumina or thoria at 500°C ., the ammonia may be replaced by various primary amines.—W. G.

Oxalic acid; Determination of —. Part 2. A. Bau. *Woch. Braun.*, 1919, 36, 293–297, 301–305, 309–312, 319–321, 327–329, 337–339, 345–347, 359–360. *Chem. Zentr.* 1920, 91, II., 160–161.

ORDINARY acetic acid may contain glyoxylic acid, which is oxidised by air to oxalic acid. It is advisable therefore to keep the calcium acetate reagent (this J., 1918, 524A, 671A) in loosely stoppered bottles and to filter it before use. In the qualitative testing for traces of oxalic acid in materials containing starch great care is necessary to remove influences which destroy or mask the oxalic acid. Light and animal charcoal must be avoided, and to prevent oxidation of ferrous salts an atmosphere of carbon dioxide is desirable. Sulphates and magnesium salts mask the determination of oxalic acid. 0.02% of oxalic acid was found in barley and rye, in peas and soya beans 0.005–0.01%, whereas oats, rye and wheat flour, and white beans gave negative results. In a Japanese beer 28.64 mg. of oxalic acid per litre was found.—H. J. II.

Chloroform from coke-oven gas. A. J. Dey. *Pharm. J.*, 1920, 104, 302.

A SAMPLE of chloroform prepared from alcohol produced from coke-oven gas (see Bury, this J., 1920, 94A) complied with all the requirements of the B.P. except that, on evaporation, it yielded a characteristic odour. The latter could be removed by treatment with sulphuric acid, and was probably due to the presence of an unsaturated hydrocarbon.—W. P. S.

Ether; Action of — on metallic mercury. D. B. Dott. *Pharm. J.*, 1920, 104, 302.

PURE ether has no action on mercury, but ether containing peroxide reacts producing a dark-coloured film on the surface of the metal. When the ether contains much peroxide (the so-called ozonic ether) a certain amount of yellow mercuric oxide may be formed. The value of ether in aiding the complete mixing of mercury and calcium carbonate in making "grey powder" is due to the

presence of an oxidising impurity in the ether; pure ether would be useless for the purpose.

PATENTS.

Ergot; Manufacture of a highly active preparation of —. Chem. Fabr. vorm. Sandoz, Basle, Switzerland. Eng. Pat. 125,396, 9.4.19. (Appl. 9006/19.) Int. Conv., 9.4.18.

POWDERED ergot is treated with a dilute aqueous acid such as oxalic acid, or solutions of acid salts, so as to render the basic constituents insoluble in the solvents subsequently used for the extraction of the fatty substances. The cellular tissue remaining after extraction of the fat is then mixed with fresh solvent to which an alkaline reagent such as barium hydroxide is added gradually until the acid is neutralised; the alkaloids are thus liberated and pass into the solvent from which they may be separated by evaporation under reduced pressure.

—D. F. T.

Arsenical compounds; Aromatic —. The Rockefeller Institute for Medical Research, Assignees of W. A. Jacobs, W. H. Brown, M. Heidelberger, and L. Pearce, New York, U.S.A. Eng. Pat. 128,181, 21.10.18. (Appl. 17,173/18.) Int. Conv., 13.6.18. Addition to 120,385 (see U.S. Pat. 1,280,123; this J., 1919, 268 A).

The sodium or potassium salts of the previously described (*loc. cit.*) N-(arsenoaryl)-bis- α -aminoacylarylamides of the general formula,

where M is the alkali metal, are equally valuable for treatment of trypanosomal or spirochetal infections and, being soluble in water, are particularly suitable for practical therapeutic use. The salts are prepared by dissolving in water equivalent quantities of the aromatic arsenic compound and the alkali hydroxide, and either evaporating to dryness under reduced pressure or precipitating the salt by the addition of a water-miscible liquid such as acetone or alcohol. The sodium salt forms a yellow powder readily soluble in water.

—G. F. M.

Gallic acid; Preparation of —. E. C. R. Marks, London. From Nitritfabrik Akt.-Ges., Koepenick, Germany. Eng. Pat. 139,419, 29.8.19. (Appl. 21,280/19.)

GALLIC acid is produced by heating to boiling solutions or suspensions of tannin with at least such quantities of metallic compounds, preferably the carbonates or hydroxides of the alkaline earths, that all the hydrogen atoms of the carboxyl and hydroxyl groups originally present and those formed by hydrolysis are substituted by the metal, and subsequently decomposing the gallates thus formed by the addition of an acid. It is advantageous to use the metallic compounds in some excess in order to assist in the coagulation of albuminous matter.

—G. F. M.

Mercuric iodide preparation; Manufacture of a —. J. Verfürth, Munich. Ger. Pat. 315,658, 9.7.16.

FATS, resins, and lipoids are added to solutions of red mercuric iodide in solvents which dissolve these substances, and the product may then be precipi-

tated by water. The precipitated mercury iodide does not turn into red mercuric iodide even on drying; it is soluble in many organic solvents such as ethyl alcohol, methyl alcohol, acetone, benzene, ethyl acetate, and ether, and can be rubbed down to yellow ointments.—J. F. B.

Hog-cholera virus; Artificial cultivation of the —. F. Proeschner, Sioux City, Iowa. U.S. Pat. 1,334,318, 23.3.20. Appl., 27.1.19.

Inulin; Process for obtaining — from plants. A. Daniel, Charlottenburg, Germany. Eng. Pat. 109,813, 18.9.17. (Appl. 13,418/17.)

SEE Ger. Pat. 313,986 of 1916; this J., 1920, 37 A.

Methyl alcohol; Manufacture of —. J. A. Christensen, Copenhagen. Eng. Pat. 125,946, 2.4.19. (Appl. 8320/19.) Int. Conv., 20.4.18.

SEE U.S. Pat. 1,302,011 of 1919; this J., 1919, 877 A.

Beta-halogen-ethylaminobenzoic esters and their derivatives. β -Alkylamino-ethylaminobenzoic alkyl esters and their derivatives. J. Altwegg and J. Landrion, Lyon, Assignors to Soc. Chim. des Usines du Rhône (anc. Gilliard, P. Monnet, et Cartier), Paris. U.S. Pats. 1,334,641—2, 23.3.20. Appl., 13.6.19.

Tobacco-leaves or leaves of like plants; Fluid for treating —. S. Hagino, Tokyo, Japan. U.S. Pat. 1,334,752, 23.3.20. Appl., 18.3.19.

SEE Eng. Pat. 137,683 of 1919; this J., 1920, 280 A.

XXII.—EXPLOSIVES; MATCHES.

Nitroglycerin waste acid mixtures; Formation of a solid phase in —. H. H. Dodds. J. S. Afr. Assoc. Anal. Chem., 1920, 3, 22—24.

FROM a sample of waste acid from nitroglycerin manufacture, kept at -3° to $+5^{\circ}$ C. in long closed glass tubes, there separated after about 5 days large transparent hexagonal crystals which continued to grow until about 15% of the acid had crystallised. In experiments with other waste acids of similar composition the crystals could not be obtained, although the original crystals continued to grow in any acid mixture of approximately the same composition up to the above-mentioned limit of 15%. The crystals had the composition:— H_2SO_4 , 79.40; HNO_3 , 3.47; HNO_2 , 0.32; H_2O (by diff.), 15.41; $\text{C}_{12}\text{H}_{11}(\text{NO}_3)_3$, 1.40%; total acidity (as HNO_3) 105.57%. Sp. gr. 1.7636 at 15° C. By recrystallising them twice at -1° C. their sulphuric acid content was raised to 82.18, and the nitric acid lowered to 1.43%, so that they gradually approached the theoretical composition of sulphuric acid monohydrate (84.48% H_2SO_4), with which also they agreed in appearance, m. pt. and sp. gr. The crystals, however, would not grow, but slowly dissolved in cooled mixtures of sulphuric acid and water (80—90% H_2SO_4) free from nitric acid. Since the crystals contain much less nitric acid than the liquid waste acid (e.g., 9.33%), a possible alternative method of denitration is suggested.—C. A. M.

Picric acid; Influence of the sulphonation of the phenol on the yield of —. M. Marquoyrol and P. Carré. Sealed note, 13.7.17. Bull. Soc. Chim., 1920, 27, 195—199.

THE yield of picric acid is much higher from phenoldisulphonic acid than from the monosulphonic acid, the difference in yield increasing with rise in the nitration temperature. In the sulphonation of the phenol the best yield of the disulphonic acid is obtained by heating 1 part of phenol with 5 parts of 93% sulphuric acid for $\frac{1}{2}$ —1

hour at 100° C. In practice the same result is attained by previously heating the sulphuric acid to 40° — 50° C. before adding the molten phenol at 50° — 60° C.—W. G.

Phenoltrisulphonic acid and its transformation into picric acid. M. Marquoyrol and P. Carré. Sealed note, 26.4.18. Bull. Soc. Chim., 1920, 27, 199—204.

By the sulphonation of phenol with ten times its weight of oleum containing 20% SO_3 , a mixture of the disulphonic and trisulphonic acids is obtained containing 80% of the trisulphonic acid. This latter acid, on nitration, gives a yield of picric acid equal to 90% of theory. Thus in the nitration of the phenolsulphonic acids the yield of picric acid increases from the mono- up to the trisulphonic acid, the accumulation of sulphonic acid groups increasing the resistance to oxidation of the molecule of phenol.—W. G.

Toxicity of picric acid. Koelsch. See XIXB.

PATENTS.

Explosive bodies; Process for producing compressed — from hexanitrodiphenylamine. O. von Schroeter, Oberlössnitz-Radebeul. Ger. Pat. 315,305, 4.2.09.

HEXANITRODIPHENYLAMINE is mixed with trinitrotoluene before compression. From a mixture of 80 parts of the former and 20 parts of the latter, bodies of sp. gr. 1.70—1.72 can be produced, which do not crack or become powdery.—J. H. L.

Matches; Manufacture of the igniting composition for — and matches manufactured by this method. O. J. Mellgren, Göteborg, Sweden. Eng. Pat. 140,026, 31.10.19. (Appl. 26,827/19.)

THE finely-divided bark of pine trees or other coniferous trees is used as a filling material and binding agent in match-head compositions.—W. J. W.

Match heads; Process of treating —. W. A. Fairburn, Great Barrington, Mass., Assignor to The Diamond Match Co., Chicago, Ill. U.S. Pat. 1,332,438, 2.3.20. Appl., 9.11.18.

MATCH-HEADS containing a gelatinous material and a chromium compound capable of interacting to produce a non-hygroscopic material are subjected after formation to the action of intense artificial light.—W. J. W.

Explosive materials; Manufacture of —. P. Landrin, Lyon, France. U.S. Pat. 1,334,462, 23.3.20. Appl., 31.1.18.

SEE Eng. Pat. 130,093 of 1918; this J., 1919, 742 A.

XXIII.—ANALYSIS.

Evaporator; Laboratory vacuum film —. H. E. Watson. J. Indian Inst. Sci., 1919, 2, 209—212.

A SMALL apparatus of the "Kestner Climbing Film Evaporator" type has been devised for laboratory purposes, and can be used either under atmospheric or reduced pressure. It comprises an evaporating tube of copper or tin, 6 ft. long and $\frac{1}{2}$ in. in external diameter; a steam jacket with upper and lower cocks; and a separator of tinned copper, the steam exit tube from which is connected to a condenser and receiver, the latter being attached by a side tube to a vacuum pump and manometer. The apparatus will evaporate 2 to 4 litres of water per hour under a pressure of 100 to 200 mm. of mercury, the steam being at atmospheric pressure.—C. A. M.

Nephelometer. C. Chéneveau and R. Audubert. Comptes rend., 1920, 170, 728—731.

THE absorption of light by the turbid medium is compensated by the displacement of a prism of

neutral-tinted glass of very slight angle. The adjustment is made so that the light transmitted by the medium and this prism fall side by side on a monochromatic green screen, and the prism is adjusted until the screen is uniformly illuminated. It is shown that the total mass, M , of the particles in suspension in the medium is a linear function of the displacement of the prism, and thus the value of M may be read off directly on a scale. (Cf. J.C.S., May.)—W. G.

Melting point; Influence of state of division on —.
F. Meissner. Z. anorg. Chem., 1920, 110, 169—186.

EXPERIMENTS with very fine powders of salol failed to show that, in a fine state of division, the melting point is lower than when the substance is in a coarser condition. In other experiments the substance was heated between a hot plate, in which a uniform temperature gradient was maintained, and a cylindrical lens, so that between the plate and lens there was a lamella of varying thickness. At that part of the plate where the temperature corresponded with the melting point a boundary line was formed between solid and liquid substance. The form of this line, in the cases of azobenzene, tristearin, and myristic acid, showed that the melting point of the thinnest lamella, 0.8μ , was distinctly lower than the normal melting point, 0.355°C . lower in the case of azobenzene and slightly less in the other cases. (Cf. J.C.S., May.)—E. H. R.

Films produced by metalloids and metals capable of being volatilised by heat; Rapid process for collecting and characterising —. A. Braly. Comptes rend., 1920, 170, 661—663.

A SIMPLE, portable apparatus for use in the field in applying the blowpipe test to minerals consists essentially of two sheets of mica mounted on some refractory material and capable of easy adjustment. On one sheet the mineral is heated in the blowpipe flame and the film is deposited on the other. By regulating the flame temperature successive films from the different metals or metalloids present in the mineral may be obtained. The usual tests for characterising the different elements present may be applied to the films.—W. G.

Manganese; Volumetric estimation of —. P. Nicolardot, A. Réglade, and M. Geloso. Comptes rend., 1920, 170, 803—810.

IS using von Knorre's method for the volumetric estimation of manganese (this J., 1902, 72), by precipitation with ammonium persulphate as the dioxide, re-solution of the precipitate in an excess of a reducing solution and back titration with a standard solution of potassium permanganate, the theoretical factor is 1 grm. $\text{Fe} = 0.4917$ grm. Mn. In practice a higher factor is necessary, owing to slight variation in the composition of the precipitate. The variations are due mainly to the presence of iron. In the absence of iron the factor found was 0.498, and in the presence of 40% of iron 0.4929. When the solution in which the precipitation takes place contains more than 10% of sulphuric acid the precipitation of the manganese is incomplete.

—W. G.

Molybdenum; Gravimetric determination of — as sulphide. J. Sterba-Böhm and J. Vostrebal. Z. anorg. Chem., 1920, 110, 81—103.

MOLYBDENUM can be precipitated quantitatively as MoS_3 by means of hydrogen sulphide in presence of formic acid if it is present entirely as molybdate; any trace of reduced molybdenum must be oxidised by means of nitric acid. A quantity of solution containing 0.1—0.3 grm. MoO_3 is diluted with water to 200—300 c.c., and formic acid is added to give a 5% solution of free

acid. If only traces of electrolytes are present in the solution, it is advisable to add a small quantity of pure potassium chloride, up to 0.75% calculated on the total volume of the solution. Directly the formic acid has been added a rapid stream of clean hydrogen sulphide (free from acid) is passed through the solution, in the cold for the first half-hour and then for 1—1½ hours at 40° — 50°C . Alternatively the hydrogen sulphide may be passed for 2 hours into a solution of the molybdate made alkaline with ammonia or potassium hydroxide, the formic acid then added, and the solution heated for one hour on the water bath. The precipitated molybdenum sulphide is washed by decantation, collected in a Gooch crucible, and dried in a current of carbon dioxide, first at 100°C . and then at 250°C . It is then cooled in the gas current and weighed in a weighing bottle. When these conditions are observed the product has the exact composition MoS_3 .—E. H. R.

Combustion of organic chloro-compounds by chromic-sulphuric acid mixture. J. Guyot and L. J. Simon. Comptes rend., 1920, 170, 734—736.

CHLORO-SUBSTITUTED esters may be estimated by oxidation with a mixture of chromic and sulphuric acids if an excess of chromic acid is used and an amalgamated copper coil is interposed between the reaction vessel and the gas burette where the carbon is measured so as to retain the chlorine. Methyl chlorosulphonate and chloroformate gave theoretical results, but in the case of the corresponding ethyl esters the ethyl group was not oxidised. Whereas acetic acid is not oxidised by this method, its chloro derivatives are completely oxidised.—W. G.

Nitrogen; The Kjeldahl method for the determination of —. I. K. Phelps and H. W. Daudt. J. Assoc. Off. Agric. Chem., 1919, 3, 218—220.

Numerous experiments were made with the object of rendering the Kjeldahl method applicable to the determination of nitrogen in all organic substances. It was found possible to determine nitrogen in the following "refractory" substances when 0.7 grm. of mercuric oxide, 10 grms. of potassium sulphate, and 25 c.c. of sulphuric acid were used for 0.2—0.4 grm. of substance, the digestion being prolonged for 2½ hrs.:—Isatin, atropine, cocaine, nicotinic acid, hydroxyquinoline, caffeine, amarine, quinoxaline hydrochloride, 2-methyl-1-quinazolinone, etc. Low results were obtained when sodium sulphate was used in place of potassium sulphate.—W. P. S.

Arginine nitrogen; Modification of the apparatus for the determination of — by Van Slyke's method. G. E. Holm. J., Amer. Chem. Soc., 1920, 42, 611—612. (See this J., 1911, 1135.)

By fitting a Kjeldahl flask with a cork carrying a tap funnel and the elongated water-jacketed tube of a Kjeldahl still-head, loss of material by bumping is prevented, and the necessity for transference of the solution after digestion with alkali is obviated.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Gallon and Whitfield. Distillation apparatus. 11,258. Apr. 23.

Garrow and Nielsen. Production of catalysts and oxygen carriers. 10,681. Apr. 17.

Lloyd. Furnaces. 10,422 and 10,433. Apr. 14.

Losey. Disintegrating fused materials. 10,947. Apr. 20.

Miller. Furnaces, ovens, kilns, etc. 10,526. Apr. 15.

Pettis. Decanting and agitating apparatus. 10,277. Apr. 13.

Schmidt. Recovering volatile solvents. 10,582. Apr. 15. (Ger., 7.8.15.)

Thäberg. 10,565. See II.

Vanneau. Grinding or crushing apparatus. 10,387. Apr. 14. (Fr., 9.11.17.)

Walker. Drying methods. 10,618. Apr. 16.

Walter. Purification of feed water for steam generators etc. 10,762. Apr. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

16,229 (1918). Fadden. Furnaces for producing mineral distillates of definite composition. (141,089.) Apr. 21.

353 (1919). Schuck. See XII.
 392 and 393 (1919). Fidler and Maxwell. Continuous kilns and dryers of tunnel and car type. (141,124—5.) Apr. 21.

5121 (1919). Brian. Vertical drying-kiln. (141,468.) Apr. 28.

12,103 (1919). Plumbridge. Recovery of volatile solvents. (141,210.) Apr. 21.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Brownlee. Lubricating oils. 10,738. Apr. 17. (U.S., 13.5.18.)

Craven and Ormandy. Production of mixed fuels consisting of solids and liquids. 10,532. Apr. 15.

Fay, and United Oil and Coal Corporation. Storage and use of colloidal fuel. 11,234. Apr. 22.

Fay, and United Oil and Coal Corporation. Fuel for furnaces of steam generators etc. 11,235. Apr. 22.

Griffin. Enrichment of producer gas. 10,496. Apr. 15.

Howgate. Retorts for manufacture of coal-gas etc. 11,000. Apr. 20.

Jackson (International Gasoline Process Corporation). Apparatus for distillation of oil. 10,446. Apr. 14.

Kopp (Wurmback and Hoeppermann.) Production of liquid fuel for explosive motors etc. 10,634. Apr. 16.

Macdonald. Apparatus for cracking oils. 11,100. Apr. 21.

Marks (Soc. Franco-Belge de Fours à Coke). Coke ovens. 10,186. Apr. 12.

Meade. Manufacture of coal gas. 10,971. Apr. 20.

Smith. Purifying mineral oils. 10,390. Apr. 14.

Thäberg. Apparatus for filtering and pressing peat etc. 10,565. Apr. 15.

Trent. Method of cleaning coal. 10,572. Apr. 15. (U.S., 9.7.19.)

Trent. Treating carbonaceous etc. material. 10,573. Apr. 15. (U.S., 16.9.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

10,352 (1918). Strache. Gasification of carboniferous substances. (117,083.) Apr. 21.

18,039 and 19,134 (1918). Wade (Le Petit). Production of liquid fuels. (141,091.) Apr. 21.

18,270 (1918). Bataafsche Petroleum Maatsch., and Brey. Rectification of hydrocarbons. (123,719.) Apr. 21.

19,677 (1918). Marks. See VII.

9491 (1919). Stafford. Destructive distillation. wood, woody fibre, etc. (141,417.) Apr. 28.

6523 (1919). Dibdin. Revivifying spent oxide. (141,172.) Apr. 21.

9491 (1919). Stafford. Destructive distillation. (141,505.) Apr. 28.

13,374 (1919). Andrews and Averill. Treating hydrocarbons for the production of lighter hydrocarbons. (141,223.) Apr. 21.

16,383 (1919). Dempster and Beard. Purifiers employed in gas-works. (141,572.) Apr. 28.

22,094 (1919). Hall Motor Fuel, Ltd., and McCrea. Desulphurising sulphur-bearing hydrocarbons. (141,272.) Apr. 21.

III.—TAR AND TAR PRODUCTS.

APPLICATION.

Tindale. Distillation of coal tar and products derived therefrom. 10,924. Apr. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

18,270 (1918). Bataafsche Petroleum Maats. See II.
1338 (1919). South Metropolitan Gas Co., and Stanier. See XX.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATIONS ACCEPTED.

17,225 (1917). Bayer and Co. Manufacture of monoazo dyestuffs. (133,012.) Apr. 21.
20,534 (1918). Imray (Soc. Chem. Ind. in Basle). Mordant dyeing disazo-dyestuffs, and their application in dyeing and printing. (141,401.) Apr. 28.
30,839 (1919). Imray (Soc. Chem. Ind. in Basle). Manufacture of monoazo dyestuffs. (141,643.) Apr. 28.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bronnert. Manufacture of viscose silk. 10,195. Apr. 12.
Bronnert. Manufacture of artificial silk. 11,362. Apr. 23.
Eastern Manufacturing Co. Finishing paper. 11,073. Apr. 21. (U.S., 9,12,16.)
Tattersall. Separating fatty etc. matters from effluents due to washing wool etc. 10,468. Apr. 15.
White. Manufacture of fibrous material from zoophytes etc. 11,415. Apr. 21.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Brandwood and Brandwood. Apparatus for dyeing yarns. 11,065. Apr. 21.
Calico Printers' Assoc., and Rouse. Printing cotton fabrics. 10,130. Apr. 12.
Calico Printers' Assoc., and Warr. Production of patterns etc. on fabrics. 10,286. Apr. 13.
Duncan. Dyeing and waterproofing material. 10,791. Apr. 19.
Nägelin. Apparatus for treating textile goods in hank form by circulating liquid. 10,429. Apr. 14. (Switz., 4,10,19.)

COMPLETE SPECIFICATIONS ACCEPTED.

20,116 (1918). Lord. Apparatus for treating hanks of yarn with liquids. (141,098.) Apr. 21.
20,534 (1918). Imray (Soc. Chem. Ind. in Basle). See IV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Bird. 10,282. See XVII.
Clayton. Sulphur-burning furnaces etc. 11,343. Apr. 23.
Dent, Golding, and United Alkali Co. Production of sulphur compounds. 10,855. Apr. 19.
Dior. Sulphuric acid chambers. 10,386. Apr. 14.
Freeth and Munro. Purification of rock-salt brine etc. 10,608. Apr. 16.
Garrow and Nielsen. 10,681. See I.
Mehner. Manufacture of cyanogen compounds. 11,116. Apr. 21. (Ger., 9,10,14.)
Soc. l'Air Liquide. Production of hydrogen peroxide. 10,751. Apr. 17. (Fr., 11,5,14.)
Wade (Lindsay Light Co.). Recovery of thorium. 11,115. Apr. 21.
Watson. Removal of arsenic from hydrochloric acid. 10,909. Apr. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

19,677 (1918). Marks (Soc. Franco-Belge de Fours à Coko). Production of sulphate of ammonia from distillation and like gases. (141,093.) Apr. 21.
365 (1919). Armour Fertilizer Works. Production of aluminium nitride. (122,829.) Apr. 28.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Clarke, Girtin, and Rhodin. Bleaching sand. 10,860. Apr. 19.
Ferguson. Manufacture of sheet glass. 11,323. Apr. 23.
Norway and Scholz. Enamel-ware. 10,261. Apr. 13.
Rollason. Manufacture of refractory materials for furnace linings. 11,002. Apr. 21.
Travers. Glass-melting pots and blocks for tank furnaces. 10,201. Apr. 12.
Virginia Plate Glass Corporation. Manufacture of glass. 10,579. Apr. 15. (U.S., 17,4,19.)

COMPLETE SPECIFICATIONS ACCEPTED.

927 (1919). Carborundum Co. Manufacture of refractory articles. (133,014.) Apr. 28.
24,884 (1919). Atkinson, Stoin and Atkinson, and Moorshead. Glass furnaces. (141,617.) Apr. 28.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Fabr. Aktiebolaget Kronsten. 11,042. See XI.
Grubenholz-Imprägnierung Ges. Impregnating wood. 10,436. Apr. 14. (Ger., 29,11,13.)
Haring, Voit, and Holzbearbeitungsges. Process of drying wood. 10,435. Apr. 14. (Ger., 28,3,19.)
Milner and Robinson. Manufacture of bricks, blocks, etc., from blast-furnace slag. 10,302. Apr. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

10,937 (1918). Hoare. Production of building material. (141,390.) Apr. 28.
180 (1919). Badder, Burrows, and Allender. Waterproof cements, concretes, and mortars. (141,113.) Apr. 21.
1113 (1919). Boillot and Daudignac. Apparatus for manufacturing cement. (141,142.) Apr. 21.
18,775 (1919). Roy. Rendering wood impermeable and recovering liquids contained therein. (140,361.) Apr. 28.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Bangerter. Metal alloy. 10,125. Apr. 12.
British Thomson-Houston Co. (General Electric Co.). Tungsten alloys. 10,756 and 10,835. Apr. 17 and 19.
Collins. Purification and recovery of tin. 10,959. Apr. 20.
Hurley. Process for galvanising or zinc-dipping articles. 10,238. Apr. 13.
Milner and Robinson. 10,302. See IX.
Minerals Separation, Ltd., and Wood. Concentration of oxidised ores. 10,929. Apr. 20.
Naef. Treatment of copper-nickel matte. 10,895. Apr. 20.
Newman, and Rustproofing Synd. Rustproofing ferrous metals etc. 11,106—8. Apr. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

16,801 (1918). Cooper Research Co. Alloys. (120,565.) Apr. 28.
18,982 (1918). Riley. Coating steel or iron with white alloy. (141,092.) Apr. 21.
374 (1919). Worrall. Hard metal alloys. (141,122.) Apr. 21.
532 (1919). Waring. Open-hearth furnaces. (141,132.) Apr. 21.
